owed to a remote common ancestor, or (the small number of common characters being considered) be an entirely independent evolution from representations of natural objects (*see* CRETE). (2) An *Art*, whose products cannot be confounded with those of any other known art by a trained eye. Its obligations to other contemporary arts are many and obvious, especially in its later stages; but every borrowed form and motive undergoes an essential modification at the hands of the Aegean craftsman, and the product is stamped with a new character. The secret of this character lies evidently in a constant attempt to express an ideal in forms more and more closely approaching to realities. We detect the dawn of that spirit which afterwards animated Hellenic art. The fresco-paintings, ceramic motives, reliefs, free sculpture and toreutic handiwork of Crete have supplied the clearest proof of it, confirming the impression already created by the goldsmiths' and painters' work of the Greek mainland (Mycenae, Thebes, Vaphio, Dendra, Tiryns). (3) *Architectural plans and decoration.* The arrangement of Aegean palaces is of two main types. First (and perhaps earliest in time), the chambers are grouped round a central court, being engaged one with the other in a labyrinthine complexity, and the greater oblongs are entered from a long side and divided longitudinally by pillars. Second, the main chamber is of what is known as the *megaron* type; i.e., it stands free, isolated from the rest of the plan by corridors, is entered from a vestibule on a short side, and has a central hearth, surrounded by pillars and perhaps hypaethral; there is no central court, and other apartments form distinct blocks. In spite of many comparisons made with Egyptian, Babylonian and "Hittite" plans, both these arrangements remain incongruous with any remains of prior or contemporary structures elsewhere. Whether either plan suits the "Homeric" palace does not affect the present question. (4) *A type of tomb*, the dome or "beehive," of which the grandest examples known are at Mycenae. The Cretan "larnax" coffins, also, have no parallels outside the Aegean. There are other infinite singularities of detail; but the above are more than sufficient to establish the point.

B. Origin and Continuity.—With the immense expansion of the evidence, due to the Cretan excavations, a question arises how far the Aegean civilization, whose total duration covers at least 3,000 years, can be regarded as one and continuous. The exploration of Cnossus shows that Aegean civilization had its roots in a primitive Neolithic period, of uncertain but very long duration, represented by a stratum which (on that site in particular) is in places nearly 20 ft. thick, and contains stone implements and sherds of hand-made and hand-polished vessels, showing a progressive development in technique from bottom to top. This Cnossian stratum seems to be throughout earlier than the lowest layer at Hissarlik. It closes with the introduction of incised, white-filled decoration on pottery, whose motives are presently found reproduced in monochrome pigment. We are now in the beginning of the bronze age, and the first of Evans's "Minoan" periods. Thereafter, by exact observation of stratification, eight more periods have been distinguished at Cnossus, each marked by some important development in the universal and necessary products of the potter's art, the least destructible and therefore most generally used archaeological criterion. These periods fill the whole bronze age, with whose close, by the introduction of the superior metal, iron, the Aegean age is conventionally held to end. Iron came into general Aegean use about 1000 B.C., and possibly was the means by which a body of northern invaders established their power on the ruins of the earlier dominion. The important point is this, that throughout the nine Cnossian periods, following the Neolithic age (named by Evans, "Minoan I. 1, 2, 3; II. 1, 2, 3; III. 1, 2, 3"; *see* CRETE), there is evidence of a perfectly orderly and continuous evolution in, at any rate, ceramic art. From one stage to another, fabrics, forms and motives of decoration develop gradually; so that, at the close of a span of more than 2,000 years, at the least, influences of the beginning can still be clearly seen and no trace of violent artistic intrusion can be detected. This fact, by itself, would go far to prove that the civilization continued fundamentally and essentially the same throughout. It is, moreover, supported by less abundant remains

of other arts. That of painting in fresco, for instance, shows the same orderly development from at any rate Period II. 2 to the end. About institutions we have less certain knowledge, there being but little evidence for the earlier periods; but in the documents relating to religion, the most significant of all, there is no trace of sharp change. We see evidence of a uniform nature worship passing through all the normal stages down to theanthropism in the latest period. There is no appearance of intrusive deities or cult-ideas. We may take it then (and the fact is not disputed even by those who believe in one thorough racial change, at least, during the bronze age) that the Aegean civilization was indigenous, firmly rooted and strong enough to remain dominant in its own geographical area throughout the bronze age.

This conclusion does not necessarily lead to the corollary that the mass of those who possessed this civilization remained for the most part racially the same throughout the bronze age. This indeed may be true for Crete, but as already indicated there are grave reasons for believing that on the mainland matters were not so simple, and herein lies the crux of Greek ethnology. A solution which would satisfy the archaeological and anthropological problems to be indicated would go far to solving the vexed questions of Hellenic origins, especially as regards Achaeans and Dorians (*see* DORIANS, ACHAEANS and IONIANS), and the first appearance of Aryans in the peninsula. In the neolithic age the general characteristics of the culture of the mainland and of Crete are quite distinct. On the mainland at the end of the neolithic age a bronze-using culture appears which is undoubtedly akin to that of the islands and Crete. In the middle period, however, about 2000 B.C., a new element comes into the mainland typified for archaeologists by a well marked class of pottery called "Minyan Ware." This occurs as an import into Melos and was even imitated there, but though contemporary Melian wares are recognized in Crete, as in the temple repositories at Cnossus, hardly a sherd of Minyan ware has been found in Crete. Suddenly, just before the beginning of the last period, Cretan influence and culture came in full force to the mainland. Some hold that this betokens a complete conquest of the mainland by Crete, wholesale displacements of population and the institution of Cretan dynasts at Mycenae and elsewhere. Others maintain that this indicates a rapid absorption by a vigorous and progressive folk of a developed culture which they adapted to their own purposes. For the latter view we can urge:—

(1) Distinct differences are observed between the products of the mainland and those of Crete and both, for instance, appear as imports in Melos side by side; (2) the oldest royal grave at Mycenae contains mostly mainland pottery, and throughout the succeeding period, though the superficial culture is Cretan, there are clear signs that its basis is the old element which produced Minyan ware; (3) there is a variation in burial customs between Crete and the mainland pointing to a divergence in belief as regards the dead; (4) the fortified castles of the mainland like Mycenae, Tiryns and Midea are in strong contrast to the undefended palaces of Crete; (5) in the earlier periods Cretan pottery, except in a few cases, has not been found outside, but the adoption of the Cretan phase of Aegean culture by the mainland just precedes the spread of the last phase of that culture far and wide in the Levant, and it is notorious that the remains from Rhodes, Cyprus and Philistia depend on the mainland and not on Crete.

All this suggests that about 1600 B.C. when the last period began some powerful folk (that which introduced Minyan pottery) arose on the mainland and quickly absorbed the mature Aegean culture of Crete, and soon after, when Crete collapsed, about 1400 B.C., the mainlanders became the dominant force and spread their version of Aegean culture abroad. The recent discoveries that the walls and palaces of Tiryns and Mycenae belong to the last phase after 1400 B.C. support this view, as also the other conclusion which places the greatest achievements of Aegean architecture, like the treasury of Atreus, in this the culminating phase of the Aegean culture, which closed perhaps with the great armada led against Troy.

A good deal of anthropometric investigation has been devoted

to human remains of the Aegean epoch, especially to skulls and bones found in Crete in tombs of Period II. The result of this, however, has established the fact that the Aegean races, as a whole, belonged to the dark, long-headed *Homo Mediterraneus*—a fact only valuable in the present connection in so far as it tends to discredit an Asiatic source for Aegean civilization, though there was clearly much affinity between Crete and south-western Asia Minor. From the skull-forms studied, it would appear, that the Aegean race was by no means pure even in the earlier Minoan periods. On the mainland indeed the skulls from Asine show that both the long and the short types were present in the middle period together with one or two examples of an "Armenoid" character. This is by no means in disagreement with archaeology. There is some ground for supposing that the language spoken in Crete before the later Doric was non-Hellenic, though perhaps Indo-European. This inference rests on three inscriptions in Greek characters but non-Greek language found in eastern Crete. The language has some apparent affinities with Phrygian. The inscriptions are post-Aegean by many centuries, but they occur in the part of the island known to Homer as that inhabited by the Eteo-Cretans, or aborigines. Their language may prove to be that of the Linear tablets.

V. HISTORY OF AEGEAN CIVILIZATION

History of an inferential and summary sort only can be derived from monuments in the absence of written records. The latter do, indeed, exist in the case of the Cretan civilization and in great numbers; but they are undeciphered and likely to remain so, except in the improbable event of the discovery of a long bilingual text, partly couched in some familiar script and language. Even in that event, the information which would be derived from the Cnossian tablets would probably make but a small addition to history, since in very large part they are evidently mere inventories of tribute and stores. The engraved gems probably record divine or human names (*see* CRETE).

(1) **Chronology.**—The first chronological datum is inferred from a close similarity between certain Cretan hand-made and polished vases of Minoan Period I. 1. and others discovered by Petrie at Abydos in Egypt and referred by him to the 1st dynasty. He goes so far as to pronounce the latter to be Cretan importations, their fabric and forms being unlike anything Nilotic. If that be so, the period at which stone implements were beginning to be superseded by bronze in Crete must be dated before 4000 B.C. But below all Evans's "Minoan" strata lies the immensely thick Neolithic deposit. To date the beginning of this earliest record of human production is impossible at present. The Neolithic stratum varies very much in depth, ranging from nearly 20ft. to 3ft., but is deepest on the highest part of the hillock. Its variations may be due equally to natural denudation of a stratum once of uniform depth, or to the artificial heaping up of a mound by later builders. Even were certainty as to these alternatives attained, we could only guess at the average rate of accumulation, which proceeds very differently on different sites and under different social and climatic conditions. In later periods at Cnossus accumulation seems to have proceeded at a rate of, roughly, 3ft. per 1,000 years. Reckoning by that standard we might push the earliest Neolithic remains back behind 10,000 B.C.; but the calculation would be worthy of little credence. Surer chronological links are provided by the close affinity with early dynastic Egyptian products shown by the stone bowls from tombs of the 1st period at Mochlos and in Mesara. At Cnossus actual Egyptian bowls of the earliest dynastic times have been found. These facts, and the parallelism displayed by Cretan seals in ivory and stone from the Mesara ossuaries and by Egyptian seals of the 1st six dynasties, enable us to say that the 1st period began before the middle of the 4th millennium. We reach another fairly certain date in the synchronism of remains belonging to the 12th dynasty (*c.* 2225 B.C.) with products of Minoan Period II. 2. Characteristic Cretan pottery of this period was found by Petrie in the Fayum and by Garstang at Abydos in conjunction with 12th dynasty remains, and various Cretan products of the period show striking coincidences with 12th dynasty styles, especially

AEGEAN CERAMICS, IVORIES AND GOLD WARE

Figs. 1 and 3. Ivory figures and heads from Knossos, Crete, probably representing athletes or acrobats. 2. A falence, or coloured and glazed earthenware, relief of a wild goat and her young, taken from the temple repository of the second palace of Knossos. 4. Reconstructed drawing of a terra-cotta figure of the first or second Thessalian period. 5. A terra-cotta head of the first Thessalian period. 6. Reproduction of the so-called Vaphio cups of chased gold, with a design of bull-fighting scenes, Mycenaean, of the period 1800-1600 B.C. 7. Birds on a triad of pillars from Knossos, Crete. 8. Jug of monochrome red ware of the first Thessalian period. 9. Reproduction of a sarcophagus from the palace at Hagia Triada, Crete, of the late Minoan period, about 1350 B.C. 10. A king's cup in gold from Dendra, near Medea. The cup, which was found in a tomb of 1350 B.C., is chased with a design of octopuses and dolphins.

in their adoption of spiraliform ornament. The spiral, however, occurs so often in natural objects (*e.g.*, horns, climbing plants, shavings of wood or metal) that too much stress must not be laid on the mutual parentage of spiraliform ornament in different civilizations. A diorite statuette, referable by its style and inscription to Dynasty 13, was discovered in deposit of Period II. 2, in the central court, and a cartouche of the "Shepherd King," Khyan, was also found at Cnossus. He is usually dated about 1633 B.C. This brings us to the next and most certain synchronism, that of Minoan Periods III. 1, 2, with Dynasty 18 (*c.* 1600-1400 B.C.). This coincidence has been observed not only at Cnossus, but previously, in connection with discoveries of scarabs and other Egyptian objects made at Mycenae, Ialysus, Enkomi, etc. In Egypt itself Kefti tributaries, bearing vases of Aegean form, and themselves similar in fashion of dress and arrangement of hair to figures on Cretan frescoes and gems of Period III., are depicted under this and the succeeding dynasties (*e.g.*, Rekhmara tomb at Thebes). Actual vases of late Aegean style have been found with remains of Dynasty 18, especially in the town of Amenophis IV.—Akhenaten—at Tell el-Amarna; while in the Aegean area itself we have abundant evidence of a great wave of Egyptian influence beginning with this same dynasty. To this wave were owed in all probability the Nilotic scenes depicted on the Mycenae daggers, on frescoes of Hagia Triada and Cnossus, on pottery of Zakro, on the shell-relief of Phaestus, etc.; and also many forms and fabrics; *e.g.*, certain Cretan coffins, and the faience industry of Cnossus. These serve to date, Periods III. 1-2 in Crete, the shaft-graves in the Mycenae circle, the Vaphio tomb, etc., to the 16th and 15th centuries B.C., and Period III. 3, the walls and palaces of Mycenae and Tiryns, the majority of the 6th stratum at Hissarlik, the Ialysus burials, the upper stratum at Phylacope, etc., to the century immediately succeeding.

The *terminus ad quem* is less certain—iron does not begin to be used for weapons in the Aegean till after Period III. 3, and then not exclusively. If we fix its introduction about 1100 B.C. and make it coincident with the incursion of northern tribes, remembered by the classical Greeks as the Dorian Invasion, we must allow that this incursion did not altogether stamp out Aegean civilization, at least in the southern part of its area. But it finally destroyed the Cnossian palace and initiated the "Geometric" age, with which, for convenience at any rate, we may close the history of Aegean civilization proper.

(2) **Annals.**—From these and other data the outlines of primitive history in the Aegean may be sketched thus. A people, agreeing in its prevailing skull-forms with the Mediterranean race of north Africa, was settled in the Aegean islands from a remote Neolithic antiquity, but, except in Crete, where insular security was combined with great natural fertility, remained in a savage and unproductive condition until far into the 4th millennium B.C. In Crete, however, it had long been in close contact with Egypt and had developed a certain civilization, and at a period more or less contemporary with Dynasties 11 and 12 (2200-2000 B.C.) the scattered communities of the centre of the island coalesced into a strong monarchical state, whose capital was at Cnossus. There the king, probably also high priest of the prevailing nature cult, built a great stone palace, and received the tribute of feudatories, of whom, probably, the prince of Phaestus, who commanded the Messará plain, was chief. The Cnossian monarch had maritime relations with Egypt, and presently sent his wares all over the southern Aegean (*e.g.*, to Melos in the earlier Second City period of Phylacope). A system of pictographic writing came into use early in this Palace period, but only a few documents, made of durable material, have survived. Pictorial art of a purely indigenous character, whether on ceramic material or plaster, made great strides, and from ceramic forms we may legitimately infer also a high skill in metallurgy. The absence of fortifications at Cnossus, Mallia, and Phaestus suggests that at this time Crete was internally peaceful and externally secure. Small settlements in close relation with the capital, were founded in the east of the island to command fertile districts and assist maritime commerce. Gournia and

Palaiakastro fulfilled both these ends; Zakro must have had mainly a commercial purpose, as the starting point for the African coast. The acme of this dominion was reached about the end of the 3rd millennium B.C., and thereafter there ensued a certain, though not very serious, decline. The period may be considered to close with a general disaster which overtook the principal Cretan sites at the end of the 17th century B.C. The cause is still to seek; some think it was due to war, others believe that it may have been the result of a terrible earthquake. This would have been caused by the explosion of the volcano of Thera which split that island in two and covered the prehistoric remains which belong to the last phase of the middle period with a deep deposit of pumice.

On the mainland the neolithic population, to judge by its brilliantly painted pottery, seems to have been distinct from that of the islands and to have been related rather to the tribes of the Danubian and Carpathian areas, which some regard as the original home of the Aryans. After the close of the first neolithic period in Thessaly a bronze-using folk, closely akin to the inhabitants of the islands, came to the mainland and advancing from the south-east gradually made themselves masters of the peninsula as far north as Othrys. When this occurred we cannot say, but as the earliest bronze age ware on the mainland is still somewhat primitive it may have taken place well before the end of the 3rd millennium B.C. Once established the bronze age people, together with the remains of the aborigines, developed on a culture parallel to that of the Cyclades, and several prosperous settlements arise as at Tiryns, Mycenae itself, Asine, Nemea, Zygouries and Korakou. If the Cretans and islanders were of non-Hellenic race, the bronze-using incomers may have introduced the non-Hellenic place-names in *-ssos* and *-nthos*. When the second period in Crete had already evolved about the beginning of the 2nd millennium B.C. a new factor entered the mainland. This was accompanied by a new kind of pottery, "Minyan Ware," but whence or how it came we do not yet know. This people seems to have coalesced readily with the pre-existing population which, as we know, already contained two racial elements, and this is reflected in the skull types from Asine. At first, though in communication with islands such as Melos and Paros, they seem to have had no contact with Crete till shortly before the end of the 17th century B.C. Then Aegean culture, as represented by the Cretan culture of the renaissance after the disaster, came into the mainland in full force. This may have been due to a conquest of the mainland by Cretans, or to the hospitable reception of refugees from the disaster in Crete, or to raids conducted by chiefs of the mainland against Crete. Whatever the cause the mainland became saturated with Cretan culture, but it still retained its own individuality, which changed and charged with its own feeling whatever was borrowed from Crete. For instance the evolution of certain mainland vase shapes continues unbroken, but is modified by the influence of Crete. Thus at the beginning of the 3rd period, almost coincident with the rise of the 18th dynasty in Egypt, we have a renaissance in Crete and the establishment of strong centres of culture at Mycenae, Thebes and other mainland sites. In Crete the palaces were rebuilt on a larger scale and with more sumptuous appointments, though there was a distinct tendency towards the baroque. The mainland followed suit, but there is almost the same quality of difference between them as there is between English and American 18th century culture. For two centuries this continued, the mainland becoming stronger and Crete weaker, till just about the time when the 18th dynasty decayed in the nerveless hands of Akhenaten, Crete collapsed and ceased to be the centre of Aegean culture. She still existed, but only as a provincial centre, down to the dawn of the iron age. Her inheritance passed to the mainland which, probably under the leadership of Mycenae, established a great dominion, such as that which Homer depicts under Agamemnon's suzerainty. This is the age of the greatest uniformity of the Aegean culture. Then arose the great Cyclopean fortresses of Tiryns and Mycenae with their palaces, then were built the proudest of the beehive tombs, then Aegean products of mainland style reached distant shores from Sicily to Philistia,

from Macedonia to Egypt. The energy of the mainlanders both in spreading abroad through the Mediterranean the culture which they had adopted as their own and in erecting monumental buildings which testify to amazing architectural skill, demonstrates that they were a people of strong character, capable and original. Were these the Achaeans? Who were the makers of Minyan ware? Were they from Asia Minor like the Tantalids; and were they, so to speak, the forerunners of the Etruscans, who in another land at a later date so quickly absorbed Hellenic culture? These are problems which cannot yet be answered, but it seems possible that Aryans may well have been resident in the peninsula long before the Homeric age and so were not northern invaders as modern criticism has asserted, for Greek tradition regarded the Achaeans as natives. The activities of the mainland folk after 1400 seem to find an echo in the Hittite tablets which record the doings of the Ahhiyava from that century onwards.

Towards the beginning of the 12th century the traditional date for the Trojan War and when Egypt was vexed by the Peoples of the Sea, signs of degeneration again appear and soon after came a final catastrophe, probably about 1100 B.C. Mycenae and Tiryns went up in flames. The palace at Cnossus was once more destroyed, and never rebuilt or re-inhabited. Iron took the place of bronze, and Aegean art, as a living thing, ceased on the Greek mainland and in the Aegean isles, including Crete, together with Aegean writing. In Cyprus, and perhaps on the south-west Anatolian coasts, the cataclysm was less complete, and Aegean art continued to languish, cut off from its fountain-head. Such artistic faculty as survived elsewhere issued in the lifeless geometric style which is reminiscent of the later Aegean, but wholly unworthy of it. Cremation took the place of burial of the dead. This great disaster, which cleared the ground for a further evolution of art, was probably due to an incursion of northern tribes, gradual rather than sudden, who were possessed of superior iron weapons—those tribes which later Greek tradition and Homer knew as the Dorians. They crushed a civilization that had outgrown its strength; and it took two or three centuries for the artistic spirit, instinct in the Aegean area, and probably preserved in suspended animation by the survival of Aegean racial elements, to blossom anew. On this conquest seems to have ensued a long period of unrest and popular movements, known to Greek tradition as the Ionian Migration and the Aeolic and Dorian "colonizations"; and when once more we see the Aegean area clearly, it is dominated by Hellenes, though it has by no means lost all memory of its earlier culture, which was after all the mainspring of the Greek genius. The darkness that shrouds the close of the bronze age was but the prelude to a brighter dawn.

(D. G. H.; A. J. B. W.)

AEGEAN SEA, an arm of the Mediterranean sea, between Greece on the west and Asia Minor on the east, and connected by the Dardanelles with the sea of Marmora, and the Black sea. The name archipelago (*q.v.*) was formerly applied scientifically to this sea. Various derivations suggest origin of "Aegean" from the town of Aegeae, or from Aegea, queen of the Amazons, who perished in this sea; or from Aegeus, father of Theseus, who drowned himself here. Structurally the sea is a much-shattered old land-block almost entirely submerged, outlined by younger fold-mountains (being continuations of ranges of Asia Minor), also partly submerged. Both features have accounted for this island-studded sea with its alternating deeps and shallows. Island chains may be traced through Chios, Psara and Skyros to the North Sporades, through Samos, Nikaria, Mykoni, Tinos, Andros and the south-east promontory of Euboea, and through Rhodes, Scarpanto, Crete and Cerigo to the south-east promontory of the Peloponnese. Between the latter chains are the great group of the Cyclades including Naxos, Paros and Milo. Islands in the northern section of the sea include Thasos, off the Macedonian coast, Samothrace, fronting the Gulf of Saros, and Imbros and Lemnos, in prolongation of the Gallipoli peninsula, while Mitylene lies off the coast of Asia Minor. Important sea basins are those of the Cretan sea with depths of over 1,000 fathoms, and the trough between Thessaly and the gulf of Saros over 600 fathoms. Many islands are of volcanic formation; and a well-defined volcanic group includes Milo, Kimolos, Santorin (Thira) and Thirasia. The larger islands have some fertile and well-watered valleys and plains. The chief productions are wheat, wine, oil, mastic, figs, raisins, honey, wax, cotton and silk. The people fish for coral and sponges, as well as for bream and mullet. Greece owns most of the islands, but a number collectively known as the Dodecanese, including Rhodes, Scarpanto, Kaxo, Astypalaea, Kharki, Symi, Tilos, Nisyros, Kos, Kalymnos, Leros and Patmos and minor ones are in Italian hands. Imbros and Tenedos remain Turkish.

AEGEUS, son of Pandion and grandson of Cecrops, was king of Athens and the father of Theseus (*q.v.*).

AEGINA (*Egina* or *Engia*), a Greek island, in the Saronic gulf, 20m. from the Piraeus. Tradition derives the name from Aegina, the mother of Aeacus, who was born in and ruled the island. In shape Aegina is triangular, 8m. long from north-west to south-east, and 6m. broad, with an area of about 41 sq.m. The western side consists of stony but fertile plains, well cultivated with grain, vines, almonds, figs and some cotton. The rest of the island is rugged. From the conical Mt. Oros at the south end, the Panhellenian ridge stretches north with narrow fertile valleys on either side. From the absence of marshes the climate is the most healthy in Greece. The island forms part of the modern *nomos* of Attica and Boeotia, of which it forms an *eparchy*. The sponge fisheries are important. The chief town is Aegina, at the north-west end of the island, the favourite summer residence of many Athenians.

Antiquities.—The well known temple stands on the ridge near the north corner of the island. In 1811 Baron Haller von Hallerstein and the English architect, C. R. Cockerell, discovered much sculpture from the pediments, which was bought in 1812 by the crown prince Louis of Bavaria and set up in the Glyptothek at Munich. The restoration by B. Thorvaldsen was drastic, ancient parts being cut away to allow of additions treated in imitation of the ancient weathering. The arrangement of the figures has been disputed. Cockerell's inward-facing groups were adopted at Munich till 1901, when Furtwängler's excavation of the site, and fresh

FROM FURTWÄNGLER, "DAS HEILIGTUM DER APHAEA," BY COURTESY OF THE BAYERISCHE AKADEMIE DER WISSENSCHAFTEN

PLAN OF THE TEMPLE OF APHAEA, IN AEGINA

This temple with its famous sculptures was subjected to violent "restoration" at the beginning of last century, but its true character was established by Herr Furtwängler's researches in 1901. Excavations have also shown that the temple belonged not to Zeus or Athena but to a local goddess Aphaea

study of the figures and fragments in Munich, led to a rearrangement which may be regarded as approaching finality. The figures no longer all face towards the centre, but are broken up, as in other early compositions, into a series of groups of two or three figures each. A figure of Athena still occupies the centre of each pediment, but is set farther forward. On each side of this, in the west pediment, is a group of two combatants over a fallen warrior; in the east pediment, a warrior whose opponent is falling into the arms of a supporting figure; other figures also—the bowmen especially—face towards the angles, and so give more variety. The west pediment, which is more conservative in type, represents the earlier expedition of Heracles and Telamon against Troy; the eastern, which is bolder and more advanced, probably refers to episodes in the Trojan war. There are also remains of a third pediment, which may have been produced in competition, but

never placed on the temple. (For the character of the sculptures see GREEK ART.) Inscriptions found by the recent excavations seem to prove that the shrine belonged not to Zeus or Athena as formerly supposed, but to the local goddess, Aphaea, identified by Pausanias with Britomartis and Dictynna. The present temple probably dates from the time of the Persian wars. In the town of Aegina itself are the remains of another temple, dedicated to Aphrodite; one column of this still remains standing, its foundations are fairly preserved, and its votive offerings are important in the early history of Greek vase painting.

HISTORY

Aegina, according to Herodotus (v. 83), was a colony of Epidaurus, to which state it was originally subject. The discovery of gold ornaments belonging to the latest period of Mycenaean art suggests the inference that the Mycenaean culture held its own in Aegina for some generations after the Dorian conquest of Argos and Lacedaemon. It is probable that the island was not Dorized before the 9th century B.C. One of the

FROM PERROT & CHIFFEZ, "HISTORY OF ART," BY PERMISSION OF CHAPMAN & HALL LTD. THE "HARPY CUP," A FAMOUS EXAMPLE OF AEGINETAN ART. THE ILLUSTRATION SHOWS PART OF THE UPPER DESIGN

earliest facts known to us in its history is its membership in the League of Calauria, which included, besides Aegina, Athens, the Minyan (Boeotian) Orchomenus, Troezen, Hermione, Nauplia and Prasiae, and was probably an organization for the suppression of piracy. It follows that the maritime importance of the island dates back to pre-Dorian times. Aegina was the first state of European Greece to coin money (see PHEIDON). Within 40 years of the invention of coinage by the Lydians (c. 700 B.C.), the Aeginetans introduced the system to the western world. The fact that the Aeginetan scale of coins, weights, etc. was in general use in the Greek world is sufficient evidence of the commercial importance of the island. In the earlier half of the 7th century B.C. it appears to have belonged to the Eretrian league. In the next century Aegina is one of the three principal states, and the only state of European Greece trading at the emporium of Naukratis (q.v.; Herod. ii. 178). At the beginning of the 5th century it seems to have been an entrepôt of the Pontic grain trade, at a later date an Athenian monopoly (Herod. vii. 147). Unlike the other commercial states of the 7th and 6th centuries B.C., Aegina founded no colonies.

The history of Aegina, as it has come down to us, is almost exclusively a history of its relations with Athens. The account which Herodotus (v. 79-80; vi. 49-51, 73, 85-94) gives of the relations between the two states is to the following effect. Thebes, after the defeat by Athens about 507 B.C., appealed to Aegina for assistance. The Aeginetans at first contented themselves with sending the images of the Aeacidae, the tutelary heroes of their island. Subsequently, however, they entered into an alliance, and ravaged the seaboard of Attica. The Athenians were preparing to make reprisals, in spite of the advice of the Delphic oracle that they should desist from attacking Aegina for 30 years, and content themselves meanwhile with dedicating a precinct to Aeacus, when their projects were interrupted by the Spartan intrigues for the restoration of Hippias. In 491 B.C. Aegina was one of the states which gave the symbols of submission ("earth and water") to Persia. Athens at once appealed to Sparta to punish this act of Medism, and Cleomenes I. (q.v.), one of the Spartan kings, crossed over to the island, to arrest those who were responsible for it. His attempt was at first unsuccessful; but, after the deposition of Demaratus, he visited the island a second time, accompanied by his new colleague Leotychides, seized ten of the leading citizens and deposited them at Athens as hostages. After the death of Cleomenes and the refusal of the Athenians to restore the hostages to Leotychides, the Aeginetans retaliated by seizing a number of Athenians at a festival at Sunium. Thereupon the Athenians concerted a plot with Nicodromus, the leader of the democratic party in the island, for the

betrayal of Aegina. He was to seize the old city, and they were to come to his aid with 70 vessels. The plot failed owing to the late arrival of the Athenian force. An engagement followed in which the Aeginetans were defeated. Subsequently, however, they succeeded in winning a victory over the Athenian fleet. The dates of these incidents are uncertain. It is unlikely that Athens was at war in 498 B.C. as she sent 20 ships to help the Ionians in revolt against Persia, and Herodotus nowhere suggests a peace earlier than 481 B.C. If we may regard the "30 years" of the Delphic oracle as fixed after the event, i.e., after the Athenian victory in 458 B.C. we may assign the dedication of the shrine to Aeacus and the beginning of the war to 488 B.C. This is supported by the building of the great Athenian fleet—"for the war against Aegina"—in 483 B.C. Overtures were unquestionably made by Thebes for an alliance with Aegina, c. 507 B.C., but they came to nothing. The refusal of Aegina was veiled under the diplomatic form of "sending the Aeacidae." The real occasion of the outbreak of the war was the refusal of Athens to restore the hostages some 20 years later. There was but one war, and it lasted from 488 to 481 B.C., when it was suspended owing to the invasion of Xerxes. That Athens had the worst of it in this war is certain. Herodotus had no Athenian victories to record after the initial success, and the fact that Themistocles was able to carry his proposal to devote the surplus funds of the state to the building of so large a fleet seems to imply that the Athenians were themselves convinced that a supreme effort was necessary. It may be noted, in confirmation of this view, that the naval supremacy of Aegina is assigned by the ancient writers on chronology to precisely this period, i.e., the years 490-480 B.C. In the repulse of Xerxes it is possible that the Aeginetans played a larger part than is conceded to them by Herodotus. The Athenian tradition, which he follows in the main, would naturally seek to obscure their services. The destruction of the Persian fleet appears to have been as much the work of the Aeginetan contingent as of the Athenian. It is difficult to credit the number of the vessels that is assigned to them by Herodotus (30 as against 180 Athenian vessels: see GREECE, *History, Bibliography*).

During the next 20 years the philo-laconian policy of Cimon (q.v.) secured Aegina, as a member of the Spartan league, from attack. The change in Athenian foreign policy, which was consequent upon the ostracism of Cimon in 461 B.C. led to war, in which the brunt of the fighting fell upon Corinth and Aegina. The latter state was forced to surrender to Athens after a siege, and to accept the position of a subject-ally (c. 456 B.C.). The tribute was fixed at 30 talents. By the terms of the Thirty Years' Truce (445 B.C.) Athens covenanted to restore to Aegina her autonomy, but the clause remained a dead letter. In the first winter of the Peloponnesian War (431 B.C.) Athens expelled the Aeginetans, and established a cleruchy in their island. The exiles were settled by Sparta in Thyreatis, on the frontiers of Laconia and Argolis. Even in their new home they were not safe from Athenian rancour. A force landed under Nicias in 424, and put most of them to the sword. At the end of the Peloponnesian War Lysander restored the scattered remnants of the old inhabitants to the island. Its greatness, however, was at an end.

It would be a mistake to attribute the fall of Aegina solely to the development of the Athenian navy. It is probable that the power of Aegina had steadily declined during the 20 years after Salamis, and that it had declined absolutely, as well as relatively to that of Athens. Commerce was the source of Aegina's greatness, and her trade, which appears to have been principally with the Levant, must have suffered seriously from the war with Persia. Her medism in 491 is to be explained by her commercial relations with the Persian Empire. She was forced into patriotism in spite of herself, and the glory won at Salamis was paid for by the loss of her trade and the decay of her marine. The completeness of the ruin of so powerful a state finds an explanation in the economic conditions of the island, the prosperity of which rested upon a basis of slave-labour. It is clear, however, that the number of slaves must have been out of all proportion to that of the free inhabitants. In this respect the history of Aegina does but anticipate the history of Greece as a whole.

The constitutional history of Aegina is unusually simple. So long as the island retained its independence the government was an oligarchy. There is no trace of the heroic monarchy and no tradition of a *tyrannis*. The story of Nicodromus, while it proves the existence of a democratic party, suggests, at the same time, that it could count upon little support.

Modern.—Aegina passed with the rest of Greece under the successive dominations of Macedon, the Aetolians, Attalus of Pergamum and Rome. In 1537 the island, then a prosperous Venetian colony, was overrun and ruined by the pirate Barbarossa (Khair-ed-Din). One of the last Venetian strongholds in the Levant, it was ceded by the treaty of Passarowitz (1718) to the Turks. In 1826–28 the town became for a time the capital of Greece and the centre of a large commercial population which has since diminished considerably.

Grundy, *The Great Persian War*, pp. 154 *et seq.*, 202 *et seq.*, 373 *et seq.*

AEGINETA, PAULUS, a celebrated surgeon of the island of Aegina, whence he derived his name. According to Le Clerc's calculation, he lived in the 4th century of the Christian era; but Abulfaragius (Bar-Hebraeus) places him with more probability in the 7th. The title of his most important work is *Ἐπιτομὴς Ἰατρικῆς Βιβλία Ἑπτὰ* (*Synopsis of Medicine in Seven Books*); the 6th book, treating of operative surgery, is of interest for surgical history.

The whole work in the original Greek was published at Venice in 1528, and another edition appeared at Basle in 1538. Several Latin translations have been published, and an excellent English version, with commentary, by Dr. F. Adams (1844–48). Edition by Heiberg (Leipzig, 1912) and German trans. with appendix by I. Berendes (Leyden, 1914).

AEGIRITE or AEGIRINE: see **ACMITE**.

AEGIS, in Homer, the shield or buckler of Zeus. It was furnished with tassels and bearing the Gorgon's head in the centre. Originally symbolical of the storm-cloud, it probably signifies rapid, violent motion (Gr. *aïssō*). In the later story Zeus is said to have used the skin of the goat Amaltheia (Gr. *aigis* = goat-skin) as a buckler when he went forth to do battle against the giants; in another legend, it is the skin of a monster slain by Athena, who afterwards wore it as a cuirass. Such skin shields were the original form of body protection, afterwards replaced by the solid shield covered with metal. It appears to have been really the goat's skin used as a belt to support the shield. When so used it would generally be fastened on the right shoulder, and would partially envelop the chest as it passed obliquely round in front and behind to be attached to the shield under the left arm. Hence, by transference, it would be employed to denote at times the shield which it supported, and at other times a cuirass. Hence the aegis appears in works of art sometimes as an animal's skin thrown over the shoulders and arms, sometimes as a cuirass, with a border of snakes corresponding to the tassels of Homer, usually with the Gorgon's head in the centre.

RESTORATION OF A STATUE OF ATHENA, WEARING THE AEGIS, A CUIRASS OF ANIMAL SKIN BORDERED WITH SNAKES AND BEARING THE HEAD OF A GORGON

AEGISTHUS, in Greek legend the son of Thyestes by his own daughter Pelopia (Hyginus, *fab.* 88). Having been exposed by his mother, he was found by shepherds and suckled by a goat

(*aîx*), whence his name. His uncle Atreus, who had married Pelopia, took him to Mycenae, and brought him up as his own son. For the rest of his story see **AGAMEMNON**, **ATREUS**.

AEGOSPOTAMI, a small creek issuing into the Hellespont, north-east of Sestos, the scene of the decisive battle in 405 B.C. in which Lysander destroyed the last Athenian squadron in the Peloponnesian War (*q.v.*). The existence of a township is attested by coins of the 5th and 4th centuries.

AEHRENTHAL, ALOYS LEXA VON, COUNT (1854–1912), Austro-Hungarian statesman, was born at Gross-Skal, in Bohemia. He was the son of Baron (Freiherr) Johann Lexa von Aehrenthal and his wife Marie, *née* Countess Thun-Hohenstein, and began his diplomatic career in 1877 as attaché to the Paris embassy under Count Beust. He went in 1878 in the same capacity to St. Petersburg, and from 1883 to 1888 he worked at the Foreign Office in Vienna under Kalnoky, with whom he formed close relations. In 1888 he was sent as councillor of embassy to St. Petersburg, where he exercised considerable influence with the ambassador, Count Wolkenstein. Recalled in 1894 to service in the Foreign Office, he undertook important duties, and in the following year went to Bucharest as ambassador. Here he succeeded in strengthening the relations between the courts of Vienna and Bucharest, the secret alliance which King Charles had concluded in 1883 with the Central European Powers being renewed on Sept. 30. In 1899 he became ambassador in St. Petersburg, where he remained until his appointment as Foreign Minister in Oct. 1906. Aehrenthal at this time thought that Austria-Hungary must, even at the cost of some sacrifice, come to an agreement with Russia. In this sense he endeavoured to continue the negotiations successfully begun by his predecessor, Prince Franz Liechtenstein (b. 1853), for the bridging over of the difference on Balkan questions between Vienna and St. Petersburg, in order to create a basis for a permanent friendly relation between Austria-Hungary and Russia. He played a principal part in concluding the Münchsteig Agreement of 1903. During the Russo-Japanese War he took a strong line in favour of a benevolent attitude on the part of the Vienna Cabinet towards Russia. When, in Oct. 1906, he succeeded Count Goluchowski as Foreign Minister he at first maintained the views which he had professed as ambassador. He was determined to preserve the interests of Austria-Hungary in the Balkans, but also showed himself prepared to meet the Russian wishes in the Dardanelles question. Accordingly he entered into negotiations, after the outbreak of the Young Turk revolution in the summer of 1908, with Isvolski, arranging with him Sept. 15 at the château of Buchlau, in Moravia, an agreement which aimed at securing for Austria-Hungary the annexation of Bosnia and Hercegovina and for Russia the opening of the Dardanelles to Russian warships.

It was only when Isvolski's proposals were wrecked on the opposition of England, and the Russian minister protested against the annexation of Bosnia and Hercegovina, which had meanwhile been accomplished, and supported the Serbs in their opposition to Austria-Hungary, that Aehrenthal abandoned the idea of a friendly accommodation with the Russian Government. In the sharp struggle during the annexation crisis, not only with Russia and Serbia, but with the Western Powers, he held with tenacious energy to his purpose, and, powerfully supported by Germany, succeeded in carrying out his intentions after excited negotiations which threatened to lead to war. The annexation of Bosnia and Hercegovina was acknowledged by the Powers; an agreement was reached with Turkey; Serbia, after long hesitation, was obliged to submit. For this achievement Aehrenthal was rewarded by his master by elevation to the rank of Count (Aug. 18, 1909), while at the courts of his opponents he was hated but respected.

This was the zenith of his political career. Aehrenthal took the greatest pains to prove in all quarters after the conclusion of the annexation crisis, that Austria-Hungary cherished no far-reaching plans of conquest. In this spirit he offered the most decided opposition to those circles at the court of Vienna which advocated a bloody reckoning with Serbia. He held fast by the Triple Alliance, for he saw in this the surest bulwark of peace.

He sought to form the most intimate relations with the German Empire, but insisted on the independence of the Habsburg Monarchy, and energetically repulsed all efforts on the part of the German chancellery to set limits to that independence. A succession of agreements which he concluded with the Italian Foreign Minister Tittoni, enabled him to maintain correct relations with the Italian Government. Yet, by the maintenance of his peace policy, which had the full approval of the Emperor Francis Joseph, he came into serious conflict with Conrad von Hötzenndorf. The battle, carried on with tenacious endurance, ended in 1911 with the victory of Aehrenthal and the resignation of Hötzenndorf.

Aehrenthal married in 1902 Pauline, Countess Széchenyi. He died Feb. 17, 1912. During his life the estimate of his policy fluctuated violently. On the one hand it was blamed as provocative, on the other as weak. After the disastrous result of the World War, bringing with it the downfall of the Habsburg Monarchy, it is still more difficult to answer the question whether the path pursued by Aehrenthal in foreign affairs was the right one. It is certain that the Entente Powers were drawn more closely together by the active part played, during his period of office, by Austria-Hungary in Balkan affairs. It is true that the chances of success for the Central Powers in an international struggle were better in the years 1909 and 1911 than in 1914. But the question remains undecided whether, if his activity had been longer continued, Aehrenthal would have been able to maintain the position of Austria-Hungary as a great power without an appeal to the decision of arms. There is no doubt that Aehrenthal was a statesman of considerable mark, a man of wide knowledge and well-ordered intelligence; he was ambitious, but not vain, and an untiring worker. Moreover, in moments of great excitement he was able to maintain outward calmness. He was convinced of his own value, but had no desire to parade it. The Emperor Francis Joseph esteemed him, stood by him in the good and evil hours of his administration of foreign affairs, and repeatedly refused to accept his tendered resignation.

See B. Molden, Alois, *Graf Aehrenthal: Sechs Jahre auswärtiger Politik Oesterreich-Ungarns* (1917); and the article "Aehrenthal" in the *Deutsche Nekrolog* (vol. xviii., 1917, pp. 230 seq.). (A. F. P.)

AELFRIC, called the "Grammarian" (c. 955–1020), English abbot and author, was educated in the Benedictine monastery at Winchester under Aethelwold, who was bishop there from 963 to 984. Aelfric gained some reputation as a scholar at Winchester, for when, in 987, the abbey of Cernel (Cerne Abbas, Dorsetshire) was finished, he was sent by Bishop Aelfheah (Alphege), Aethelwold's successor, at the request of the chief benefactor of the abbey, the ealdorman Aethelmaer, to teach the Benedictine monks there. He was then in priest's orders. Aethelmaer and his father, Aethelweard, were both enlightened patrons of learning, and became Aelfric's faithful friends.

It was at Cernel, and partly at the desire, it appears, of Aethelweard, that he planned the two series of his English homilies (ed. Benjamin Thorpe, 1844–46, for the Aelfric Society), compiled from the Christian fathers, and dedicated to Sigeric, archbishop of Canterbury (990–94). The Latin preface to the first series enumerates some of Aelfric's authorities, the chief of whom was Gregory the Great. In the preface he regrets that, except for Alfred's translations, Englishmen had no means of learning the true doctrine as expounded by the Latin fathers. The first series of 40 homilies is devoted to plain and direct exposition of the chief events of the Christian year; the second deals more fully with church doctrine and history. Aelfric denied the immaculate birth of the Virgin (*Homilies*, ed. Thorpe, ii. 466), and his teaching on the Eucharist in the *Canons* and in the *Sermo de sacrificio in die pascae* (*ibid.* ii. 262, *et seq.*) was appealed to by the Reformation writers as a proof that the early English church did not hold the doctrine of transubstantiation.

See *A Testimonie of Antiquitie, shewing the auncient fayth in the Church of England touching the sacrament of the body and bloude of the Lord here publicly preached*, printed by John Day (1567). It was quoted in John Foxe's *Actes and Monuments* (ed. 1610).

His Latin *Grammar* and *Glossary* (ed. J. Zupitza in *Sammlung englischer Denkmäler*, vol. i., 1880), were written for his pupils

after the two books of homilies. A third series of homilies, the *Lives of the Saints*, dates from 996 to 997. Some of the sermons in the second series had been written in a kind of rhythmical, alliterative prose, and in the *Lives of the Saints* (ed. W. W. Skeat, 1881–1900, for the Early English Text Society) the practice is so regular that most of them are arranged as verse by Prof. Skeat. By the wish of Aethelweard he also began a paraphrase (ed. by Edward Thwaites as *Heptateuchus*, Oxford, 1698) of parts of the Old Testament, but under protest, for the stories related in it were not, he thought, suitable for simple minds. It has been suggested that this part of his life was chiefly spent at Winchester; but his writings for the patrons of Cernel, and the fact that he wrote in 998 his *Canons* as a pastoral letter for Wulfsgie, the Bishop of Sherborne, the diocese in which the abbey was situated, afford presumption of continued residence there. He became, in 1005, the first abbot of Eynsham or Ensham, near Oxford, another foundation of Aethelmaer's. After his elevation he wrote an abridgment for his monks of Aethelwold's *De consuetudine monachorum*, adapted to their rudimentary ideas of monastic life; a letter to Wulfgeat of Ylmandun (*i.e.*, Ilmington on the borders of Warwickshire and Gloucestershire); an introduction to the study of the Old and New Testaments (about 1008, ed. William L'Isle in 1623); a Latin life of his master Aethelwold; a pastoral letter for Wulfstan, archbishop of York and bishop of Worcester, in Latin and English; and an English version of Bede's *De Temporibus*. The *Colloquium*, a Latin dialogue designed to serve his scholars as a manual of Latin conversation, may date from his life at Cernel. It is safe to assume that the original draft of this, afterwards enlarged by his pupil, Aelfric Bata, was by Aelfric, and represents what his own scholar days were like. The last mention of Aelfric Abbot, probably the grammarian, is in a will dating from about 1020.

BIBLIOGRAPHY.—Sketches of Aelfric's career are in B. Ten Brink's *Early English Literature (to Wiclif)*, trans. H. M. Kennedy, New York, 1883, p. 105–12, and by J. S. Westlake in *The Cambridge History of English Literature* (vol. i., 1907, p. 116–129). An excellent bibliography and account of the critical apparatus is given in R. Wülker's *Grundriss zur Geschichte der angelsächsischen Literatur* (Leipzig, 1885, p. 452–80). See also the account by Prof. Skeat in pt. iv. p. 8–61 of his edition of the *Lives of the Saints*, already cited, which gives a full account of the mss., and a discussion of Aelfric's sources, with further bibliographical references; and C. L. White, *Aelfric, a New Study of his Life and Writings* (1898) in the "Yale Studies in English." The *Canons* and the pastoral to Wulfstan were printed by B. Thorpe in *Ancient Laws and Institutes of England* (1840), and the life of Aethelwold was included by J. Stevenson in the *Chron. Monast. de Abingdon* (vol. ii., p. 253–66, Rolls Series, 1858). For the version of Aethelwold's *De Consuetudine Monachorum* see E. Breck, *A Fragment of Aelfric* (Leipzig, 1887), and for the version of Bede's *De Temporibus*, Oswald Cockayne, *Leechdoms, Wortcunning and Starcraft* (vol. iii. p. xiv–xix, and p. 233 *et seq.*, Rolls Series, 1866). *Alcuini Interrogationes, Sigewulfi Presbyteri in Genesim* (ed. G. E. McLean, Halle, 1883) is attributed to Aelfric by its editor. There are other isolated sermons and treatises by Aelfric printed in Grein's *Bibl. V. A. S. Prosa* (vol. iii.).

AELIA CAPITOLINA. The destruction of Jerusalem and the Temple in A.D. 70 was followed by a second revolt of the Jews. After their defeat Hadrian made the ruined Jerusalem into a Roman colony, Aelia Capitolina, subordinate to Caesarea, the then capital of Palestine (about A.D. 130). Aelia commemorated the emperor's family name; Capitolina is derived from Jupiter Capitolinus to whom a temple was built on the site of the Jewish Temple.

AELIAN (AELIANUS TACTICUS), Greek military writer of the 2nd century A.D., resident at Rome. He is sometimes confused with his namesake Claudius Aelianus (*q.v.*). Aelian's military treatise, *Τακτικὴ Θεωρία*, is dedicated to Hadrian, though this is probably a mistake for Trajan, and the date A.D. 106 has been assigned to it. It is a handbook of Greek, *i.e.* Macedonian, drill and tactics as practised by the Hellenistic successors of Alexander the Great. The author claims to have consulted all the best authorities, the chief of which was a lost treatise on the subject by Polybius. Perhaps the chief value of Aelian's work lies in his critical account of preceding works on the art of war and in the fullness of his technical details in matters of drill. Critics of the 18th century thought Aelian greatly inferior to Arrian, but on

the Byzantines, and on the Arabs, who translated the text for their own use, Aelian exercised a great influence. The emperor Leo VI. incorporated much of Aelian's text in his own work on the military art. The Arabic version of Aelian was made about 1350. The copious details to be found in the treatise made it valuable to the army organizers of the 16th century. The Macedonian phalanx of Aelian had many points of resemblance to the solid masses of pikemen and the "squadrons" of cavalry of the Spanish and Dutch systems, and the translations made in the 16th century formed the groundwork of numerous books on drill and tactics. It has been suggested that Aelian was the real author of most of Arrian's *Tactica*, and that the *Taktikē Oeuplia* is a later revision of this original, but the theory is not generally accepted.

BIBLIOGRAPHY.—First edition of Greek text by Robortelli (Venice, 1552); the Elzevir text (Leyden, 1613) has notes. The text in W. Rüstow and H. Köchly's *Griechische Kriegsschriftsteller* (1855) has a translation, notes and reproductions of the original illustrations.

AELIAN (CLAUDIUS AELIANUS), Roman author and teacher of rhetoric, born at Praeneste, flourished under Septimius Severus and probably outlived Elagabalus (d. 222). He spoke Greek so perfectly that he was called "honey-tongued" (*μελιγλωσσος*) and wrote in Greek himself. His chief works are: *De natura animalium*, curious stories of animal life, frequently used to convey moral lessons (ed. Schneider, 1784; Jacobs, 1832); *Variae historiae* in 14 books, some of which are fragmentary, consisting mainly of anecdotes of men and customs (ed. Lünemann, 1811). Both works are valuable for the numerous excerpts from older writers. Twenty *Peasants' Letters*, after the manner of Alciphron but inferior, are also attributed to him.

Editio princeps of complete works by Gesner (1556); Hercher (1864-66). English translation of the *Various History* only by Fleming (1576), and Stanley (1665) of the *Letters* by Quillard (French) (1895).

AELRED (AELRED, ETHELRED) (1109?-1166), English theologian, historical writer, and abbot of Rievaulx, was born at Hexham about the year 1109. In his youth he was at the court of Scotland as an attendant of Henry, son of David I. He renounced the prospect of a bishopric to enter the Cistercian house of Rievaulx in Yorkshire, founded in 1131 by Walter Espec. He was for a brief period abbot of Revesby, Lincolnshire, but in 1146 returned to Rievaulx as abbot. He led a life of the severest asceticism, and was credited with the power of working miracles. In 1164 he went as a missionary to the Picts of Galloway, where he accomplished a great work of pacification. Two years later he died at Rievaulx in the 57th year of his age. In 1191 he was canonized. His writings are voluminous and have never been completely published. Amongst them is the tract called *Relatio de Standardo*, an account of the Battle of the Standard (1138), better known than the similar account by Richard of Hexham but less trustworthy.

BIBLIOGRAPHY.—See the *Vita Alredi* in John Tynemouth's *Nova Legenda Anglie* (ed. C. Horstmann, 1901, vol. i. p. 41), whence it was taken by Capgrave. From Capgrave the work passed into the Bollandist *Acta Sanctorum* (Jan. ii. p. 30). This life is anonymous but of an early date. The most complete printed collection of Aelred's works is in Migne's *Patrologia Latina*, vol. xcvi.; but this does not include the *Miracula Hagulstaldensis Ecclesiae* which are printed in J. Raine's *Priory of Hexham*, vol. i. (Surtees Society, 1864). A complete list of works attributed to Aelred is given in T. Tanner's *Bibliotheca Britannico-Hibernica* (1748), pp. 247-248. The *Relatio de Standardo* has been critically edited by R. Howlett in *Chronicles, etc., of Stephen, Henry II. and Richard I.*, vol. iii. (Rolls Series, 1886).

AEMILIA VIA or **AEMILIAN WAY**. (1) A high road of Italy, constructed in 187 B.C. by the consul M. Aemilius Lepidus, whence its name; it ran from Ariminum to Placentia, a distance of 176m. almost straight N.W., with the plain of the Po

(Padus) on the right, and the Apennines on the left. The 79th milestone from Ariminum found in the bed of the Rhenus at Bononia records the restoration of the road by Augustus from Ariminum to the river Trebia in 2 B.C. The bridge by which it crossed the Sillaro was restored by Trajan in A.D. 100. The modern high road follows the ancient line, and has some original and some fine modern bridges. After Augustus, the road gave its name to the eighth region of Italy.

(2) A road constructed in 109 B.C. by the censor, M. Aemilius Scaurus, from Vada Volaterrana and Luna to Vada Sabatia and thence over the Apennines to Dertona (Tortona), where it joined the Via Postumia from Genua (Genoa) to Cremona. We must, however, suppose that a coast road from Vada Volaterrana to Genua at least existed before the Via Postumia was built in 148 B.C. According to Polybius the Romans had in his time built the coast road from the Rhone to Carthago Nova; and it is incredible that the coast road in Italy itself should not have been constructed previously.

AEMILIUS, PAULUS (PAOLO EMILIO) (d. 1529), Italian historian, was born at Verona. He obtained such repute in his own country that he was invited to France in the reign of Charles VIII. in order to write in Latin the history of the kings of France, and was presented to a canonry in Notre Dame. He enjoyed the patronage and support of Louis XII. He died at Paris on May 5, 1529. His *De Rebus gestis Francorum* was translated into French in 1581, and has also been translated into Italian and German.

AENEAS, son of Anchises and Aphrodite. In Homer, he is represented as a favourite of the gods, who frequently interpose to save him from danger (*Iliad*, v. 311; xx. 308) as he was destined to rule the surviving Trojans after the war. The story of his emigration is post-Homeric, and is set forth in its fullest development by Virgil in the *Aeneid*. Carrying his aged father and household

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

A MEDIAEVAL ENAMEL ON COPPER OF ABOUT A.D. 1525-30 SHOWING AENEAS LEADING THE TROJANS IN THEIR STRUGGLE AGAINST THE GREEKS WHO HAVE ENTERED THE CITY IN THE BELLY OF THE WOODEN HORSE. THE ORIGINAL IS IN RICH SUBDUED COLOURS AND GOLD

gods on his back and leading his little son Ascanius by the hand, he made his way to the coast, his wife Creusa being lost during the confusion of the flight. After a perilous voyage to Thrace, Delos, Crete and Sicily (where his father died), he was cast up by a storm, sent by Juno, on the African coast.

Refusing to remain with Dido, queen of Carthage, who in despair put an end to her life, he sailed from Africa, and seven years after leaving Troy, reached the mouth of the Tiber. He was hospitably received by Latinus, king of Latium, was betrothed to his daughter Lavinia, and founded a city called Lavinium after her. Turnus, king of the Rutuli, a rejected suitor, took up arms against

him and Latinus, but was defeated and slain by Aeneas on the river Numicius. The story of the *Aeneid* ends with the death of Turnus. According to Livy (i. i. 2), Aeneas, after reigning a few years over Latium, was slain by the Rutuli; after the battle, his body could not be found, and he was supposed to have been carried up to heaven. He received divine honours, and was worshipped under the name of *Iuppiter Indiges* (Dionysius Halic. i. 64).

See Schwegler, *Römische Geschichte* (1867); Roscher's *Lexikon*, s.v.

Romances.—The story of Aeneas, as a sequel to the legend of Troy, formed the subject of several epic romances in the middle ages. The *Roman d'Énéas* (c. 1160, or later), of uncertain authorship, the first French poem directly imitated from the *Aeneid*, is a fairly close adaptation of the original, but with the characteristic tone of a mediaeval romance. On this work were founded the *Eneide* or *Eneit* (between 1180 and 1190) of Heinrich von Veldeke, written in Flemish and now only extant in a version in the Thuringian dialect, and the *Eneydos*, written by William Caxton in 1490.

See *Énéas*, ed. J. Salverda de Grave (Halle, 1891); also A. Peij, *Essai sur le romans d'Énéas* (1856); A. Duval in *Hist. littéraire de la France*, xix.; Veldeke's *Eneide*, ed. Ettmueller (Leipzig, 1852) and O. Behaghel (Heilbronn, 1882); *Eneydos*, ed. F. J. Furnivall (1890). For Italian versions see E. G. Parodi in *Studi di filologia romanza* (v. 1887).

AENEAS SILVIUS: see PRUS II.

AENEAS TACTICUS (4th century B.C.), Greek writer. According to Aelianus Tacticus and Polybius, he wrote a number of treatises (*ὑπομνήματα*) on the art of war; the only one extant deals with the defence of fortified cities, and is chiefly valuable as containing a large number of historical illustrations. Aeneas was considered by Casaubon to have been a contemporary of Xenophon and identical with the Arcadian general Aeneas of Stymphalus, whom Xenophon (*Hellenica*, vii. 3) mentions as fighting at the battle of Mantinea (362 B.C.).

Editions in I. Casaubon's (1619), Gronovius' (1670) and Ernesti's (1763) eds. of Polybius; also separately, with the notes by J. C. Orelli (Leipzig, 1818). Other texts are those of W. Rüstow and H. Köchly, *Griechische Kriegsschriftsteller*, vol. i. (Leipzig, 1853), and A. Hug, *Prolegomena Critica ad Aeneae . . . editionem* (Zürich univ. 1874), R. Schoene (Leipzig, 1911). See L. W. Hunter, *Aeneas on Siegescraft* (revised by S. A. Handford, 1927), an edition with translation and introduction, and the bibliography there given.

AENESIDEMUS, Greek philosopher, was born at Cnossus, in Crete and taught at Alexandria, probably during the 1st century B.C. He was the leader of what is sometimes known as the third sceptical school and revived to a great extent the doctrine of Pyrrho and Timon. His chief work was the *Pyrrhonian Principles* addressed to Lucius Tubero. His philosophy consisted of four main parts: the reasons for scepticism and doubt, the attack on causality and truth, a physical theory and a theory of morality. The reasons for doubt are given in the form of the ten "tropes": (1) different animals manifest different modes of perception; (2) similar differences are seen among individual men; (3) even for the same man, sense-given data are self-contradictory; (4) vary from time to time with physical changes, and (5) according to local relations; (6) and (7) objects are known only indirectly through the medium of air, moisture, etc., and are in a condition of perpetual change in colour, temperature, size and motion; (8) all perceptions are relative and interact one upon another; (9) our impressions become less deep by repetition and custom; and (10) all men are brought up with different beliefs, under different laws and social conditions. Truth varies infinitely under circumstances whose relative weight cannot be accurately gauged. There is, therefore, no absolute knowledge, for every man has different perceptions, and groups his data in methods peculiar to himself. In attacking causality he adduces almost entirely those considerations which are the basis of modern scepticism. Cause has no existence apart from the mind which perceives; its validity is ideal. The relation between cause and effect is unthinkable. If the two things are different, they are either simultaneous or in succession. If simultaneous, cause is effect and effect cause. If not, cause must precede effect, and there must be an instant when cause is not effective, that is, is not itself. Thus he arrives at the fundamental principle of scepticism, the universal opposition of causes: παντὶ λόγῳ λόγος ἀντίκειται (see SCEPTICISM).

For the immediate successors of Aenesidemus see AGRIPPA, SEXTUS EMPIRICUS. See also CARNEADES and ARCESILAUS. Of the *πυρρώνειοι λόγοι* nothing remains; we have, however, an analysis in the *Myriobiblion* of Photius.

AEOLIAN HARP, a stringed musical instrument, played automatically by the wind. It consists of a long narrow sound

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART NEW YORK

A SPECIMEN OF THE AEOLIAN HARP, WHICH WAS PLAYED AUTOMATICALLY BY THE WIND

box made of deal or pine over which ten or a dozen catgut strings of varying thickness are stretched. The sounds are produced by the play of the wind across the strings causing them to vibrate in aliquot parts, i.e. (the fundamental note not being heard) the half or octave, the third or interval of the twelfth, the second octave, and the third above it, in fact the upper partials of the strings in regular succession.

The principle of the natural vibration of strings by the pressure of the wind was recognized in ancient times. King David, we learn from the Rabbinic records, used to hang his *kinnor* (*kithara*) over his bed at night, when it sounded in the midnight breeze. The same is related of St. Dunstan of Canterbury who was in consequence charged with sorcery. The Chinese at the present day fly kites of various sizes, having strings stretched across apertures in the paper, which produce the effect of an aerial chorus.

AEOLINA, the original and more elegant name of the humble instrument familiarly known as the mouth-organ, another name for it being the mouth-harmonica. It was invented in 1829 by Sir Charles Wheatstone, who also invented the concertina, embodying the same principle, and consists simply of free reeds arranged within a small metal box, so that, each reed having a separate air aperture, it is possible by moving the instrument to right and left against the lips, to produce different notes. The mouth-organ may be regarded as a humble relation not only of the concertina (*q.v.*) and the accordion (*q.v.*) but also of the harmonium (*q.v.*).

AEOLIS (AEOLIA), an ancient district of Asia Minor, colonized at a very early date by Aeolian Greeks. The name was applied to the coast from the river Hermus to the promontory of Lectum, i.e., between Ionia to south and Troas to north. The Aeolians founded twelve cities on the mainland, including Cyme, and numerous towns in Mytilene; they were said also to have settled in the Troad and even within the Hellespont.

AEOLODION (also known as AEOLINE and AEOLODICON), one of several instruments of the harmonium type, invented and developed during the early part of the 19th century, having steel springs instead of the usual reeds. A closely similar instrument, employing wooden reeds instead of steel, was the aeolsklavier, and yet another was the aeolomelodicon or choraleon, in which the reeds were supplemented by brass tubes. The aeolopantalon in turn was in the nature of a combined harmonium and pianoforte designed so that either the one or the other could be used at will. None of these instruments succeeded in establishing itself.

AEOLUS (i-öl-ōs), in Greek mythology, according to Homer the son of Hippotes, controller of the winds, and ruler of the floating island of Aeolia. In the *Odyssey* (x. 1) he entertains Odysseus, gives him a favourable wind, and a bag in which the unfavourable winds are confined. To see what it contains Odysseus' companions open the bag; the winds escape and drive them back to the island, whence Aeolus dismisses them with

bitter reproaches. He has been identified with Zeus, and his six sons and six daughters with the 12 months. According to Virgil, Aeolus dwells on one of the Aeolian islands to the north of Sicily, Lipara or Strongyle (Stromboli), where he keeps the winds imprisoned in a vast cavern (Virgil, *Aen.* i. 52).

AEON, or **EON**, a Greek term used to denote an indefinite duration of time; and hence an existence that continues for ever. In the latter sense it was used by the Gnostic sects to denote those eternal beings or manifestations which emanated from the one incomprehensible and ineffable God. (See **GNOSTICISM**.)

AEPINUS, FRANZ ULRICH THEODOR (1724–1802), German natural philosopher, was born at Rostock, Saxony, on Dec. 13 1724. In 1757 he settled in St. Petersburg as member of the imperial academy of sciences and professor of physics, and remained there till his retirement in 1798. The rest of his life was spent at Dorpat, where he died on Aug. 10, 1802.

Aepinus is best known by his researches, theoretical and experimental, in electricity and magnetism, and his principal work *Tentamen Theoriae Electricitatis et Magnetismi*, published at St. Petersburg in 1759, was the first systematic attempt to apply mathematical reasoning to these subjects. His discussion of the effects of parallax in the transit of a planet over the sun's disc excited great interest, having appeared (in 1764) between the dates of the two transits of Venus that took place in the 18th century.

AEPYORNIS, a genus of large extinct flightless birds, comprising the family Aepyornithidae and the order Aepyornithiformes of the Palaeognathidae; they resembled the moas (*q.v.*) in many particulars, and inhabited Madagascar up to, possibly, 200 years ago. They are said to have been the origin of the legend of the roc. *Ae. titan* reached a height of 10ft., and the egg was larger than that of any other bird. (See **ORNITHOLOGY**.)

AEQUI, an ancient people of Italy, whose name occurs constantly in Livy's first decade as hostile to Rome in the first three centuries of the city's existence. They occupied the upper reaches of the valleys of the Anio, Tolenus and Himella; the last two being mountain streams running northward to join the Nar. They were not finally subdued until the end of the second Samnite War, when they seemed to have received a limited form of franchise. After the Social War the folk of Cliternia and Nersae appear united in a *res publica Aequiculorum* which was a *municipium* (*q.v.*) of the ordinary type. The Latin colonies of Alba Fucens (304 B.C.) and Carsoli (298 B.C.) must have spread the use of Latin (or what passed as such) all over the district; through it lay the chief (and for some time the only) route (via Valeria) to Luceria and the south. At the end of the republican period the Aequi appear, under the name Aequiculi or Aequicoli, organized as a *municipium*, the territory of which seems to have comprised the upper part of the valley of the Salto, still known as Cicolano.

Of the language spoken by the Aequi before the Roman conquest we have no record; but since the Marsi (*q.v.*) who lived farther east, spoke in the 3rd century B.C. a dialect closely akin to Latin, and since the Hernici (*q.v.*) their neighbours to the south-west, did the same, we have no ground for separating any of these tribes from the Latian group.

See the articles **MARSI**, **VOLSCI**, **LATINI**, and the references there given; the place-names and other scanty records of the dialect are collected by R. S. Conway, *The Italic Dialects*, pp. 300 *et seq.* (1897).

AERARI, a class of Roman citizens subject to a poll-tax arbitrarily fixed by the censor (from Lat. *aes*, in its subsidiary sense of "poll-tax"). They were (1) the inhabitants of conquered towns who possessed the *ius conubii* and *ius commercii*, but no political rights; Caere is said to have been the first example of this (353 B.C.); (2) full citizens subjected to civil degradation (*infamia*) owing to their employment or to conviction for crime; (3) persons branded by the censor. Those who were thus excluded from the tribes and centuries had no vote, were incapable of filling Roman magistracies and could not serve in the army. According to Mommsen, the *aerarii* were originally the non-*assidui* (non-holders of land). The expressions "tribu movere" and "aerarium facere" are explained by A. H. J. Greenidge—the first as relegation from a higher to a lower tribe or total exclu-

sion from the tribes, the second as exclusion from the centuries. Other views of the original *aerarii* are that they were: artisans and freedmen (Niebuhr); inhabitants of towns united with Rome by a *hospitium publicum*, who had become domiciled on Roman territory (Lange); only a class of degraded citizens, including neither the *cives sine suffragio* nor the artisans (Madvig); identical with the *capite censi* of the Serbian constitution (Belot. Greenidge).

BIBLIOGRAPHY.—See A. H. J. Greenidge, *Infamia in Roman Law* (1894), where Mommsen's theory is criticized; A. S. Wilkins in Smith's *Dict. of Greek and Roman Antiquities* (3rd ed., 1891); J. E. Sandys, *Companion to Latin Studies*, with useful bibliography (1921); W. E. Heitland, *The Roman Republic* (1923).

AERARIUM, in ancient Rome the public treasury. The treasury contained the moneys and accounts of the State, the standards of the legions, the public laws, the decrees of the senate, etc. These were deposited in the temple of Saturn and, during the republic, were in charge of the urban quaestors (see **QUAESTOR**), under the control of the senate. In 28 B.C. Augustus transferred the *aerarium* to two *praefecti aerarii*; in 23 B.C. these were replaced by two praetors (*praetores aerarii* or *ad aerarium*), selected by lot during their term of office. In addition to the common treasury, there was a special reserve fund, also in the temple of Saturn, the *aerarium sanctum* (or *sanctius*), originally consisting of the spoils of war, afterwards maintained chiefly by a 5% tax on the value of all manumitted slaves.

This fund was not to be touched except in cases of extreme necessity. Under the emperors the senate continued to have the nominal management of the *aerarium*, while the emperor had a separate exchequer, called *fiscus*, filled largely with the profits from the imperial domains in Egypt and elsewhere. But after a time, as the power of the emperors increased, this distinction virtually ceased. Besides creating the *fiscus*, Augustus also established in A.D. 6 a military treasury (*aerarium militare*), endowed by the emperor himself (see *Monumentum Ancyranum*, iii. 35) and supported by the proceeds of the tax on public sales and the succession duty. Its administration was in the hands of three *praefecti aerarii militaris*, senators of praetorian rank.

The *tribuni aerarii* have been the subject of much discussion. By the *lex Aurelia* (70 B.C.) the list of *iudices* (jurymen) was composed, in addition to senators and equites, of *tribuni aerarii*. Whether these were the successors of the *tribuni aerarii* who in earlier times were paymasters of the troops, etc., or a new order closely connected with the equites, is uncertain. According to Mommsen, they were persons who possessed the equestrian census, but no public horse. They were removed from the list of *iudices* by Caesar, but replaced by Augustus. According to Madvig, the original *tribuni aerarii* were not officials but private individuals of considerable means, who undertook certain financial work connected with their own tribes. The term was subsequently extended to include all those who possessed the property qualification that would have entitled them to serve as *tribuni aerarii*.

BIBLIOGRAPHY.—See Tacitus, *Annals*, xiii. 29, with Furneaux's notes; J. E. Sandys, *Companion to Latin Studies* (1921), useful bibliography. On the *tribuni aerarii*, see A. H. J. Greenidge, *Legal Procedure* (1901); W. E. Heitland, *The Roman Republic*, §957 (1923).

AERATED BREAD. Ordinary bread is leavened by yeast, the vesicular texture being imparted by the consequent fermentation, which produces carbonic acid gas. Dr. Daughlish invented a process by which bread is directly charged with carbonic acid gas, and to bread so lightened the name "aerated" is given. Machinery for the purpose was first devised about 1860. In the aerating process, the carbonic acid gas is supplied to the flour in conjunction with the water, and the lightening is thus performed without any decomposition whatever. For this reason it is claimed that aerated bread will agree with persons who find they cannot digest ordinary bread through the fermenting process continuing after the bread is eaten.

The mixing of aerated bread is performed in a hollow air-tight receptacle by the revolution of iron arms fixed upon a central spindle. Aerated water is pumped into the mixing receptacle at a very high pressure, and when the kneading is finished a valve is opened

at the bottom of the mixer and the dough is forced out by the elasticity of its contained carbonic acid gas. As the dough issues from the machine it is cut off in portions of the required weight and goes forward in tins to the oven. The aerated process is much quicker than the ordinary method of bread-making with yeast, as with the former an hour and a half serves for the entire conversion of a sack of flour into baked loaves, whereas with the latter process four or five hours are occupied in the formation of the dough and a further period of approximately an hour and a half in the moulding and baking.

The aerating process is said to prevent deterioration of the flour, which takes place with certain grades in the fermented process because the prolonged action of warmth and moisture changes the starchy matter of the flour into dextrine. With the aerating process there is no time for the glucogenic change to take place. Another advantage claimed for the aerating process is uniformity of result. Owing to differences in the character and rapidity of fermentation dependent on variations of temperature, quality of yeast, etc., the manufacture of fermented bread presents vagaries and irregularities which are not present in the aerated method.

AERATED WATERS or CARBONATED BEVERAGES. These may be divided into two classes, namely, aerated table-waters and effervescent beverages. The latter are flavoured and are known in the United States as carbonated beverages, also as "soda-water," "soda" and "pop" and include ginger-ales.

Natural and synthetic flavours are used. Natural flavours are from fruits, nuts, roots, herbs, bark and leaves of plants.

Synthetic flavours are also made in the laboratory. Aerated waters are essentially non-alcoholic beverages artificially saturated at the normal temperature with carbon dioxide, the pressure varying according to the type of beverage. Artificially aerated waters had their inception in Priestley's success in 1772 in producing aerated water in imitation of naturally aerated mineral spring water. Large-scale manufacture of aerated water was commenced by Paul at Geneva in 1790 and shortly afterwards by Schweppe in London. In the United States Priestley's experiments interested a Philadelphia physician, Dr. Philip Syng Physick, and he induced a chemist, Townsend Speakman, of the same city, to prepare carbonated water for his patients. Speakman added fruit juice as a flavour and the soft-drink industry in the United States started at that time, 1807. From the original conception of the imitation of natural carbonated water from springs the industry has broadened to include the production of aerated sweetened drinks and substitutes for beverages, such as cider, which are aerated by fermentation. The technique of large-scale aerated-water manufacture and the apparatus employed have undergone very considerable improvement within the last 20 years. Small-scale production of aerated water has also been rendered much simpler than formerly, when the cumbersome seltzogene apparatus was the only means for small-scale aeration of water.

Raw Materials.—Used in the manufacture of aerated waters are water, carbon dioxide, sugar and certain artificial sweeteners, acidifying materials, fruit juices, artificial fruit essences, essential

oils, vegetable extracts, mineral salts and foam-producing materials. The water employed must be unexceptionable as regards purity, both from chemical and bacteriological standpoints. To this end it is customary to filter the water through an effective filtering medium, for example, kieselguhr, unglazed porcelain, filter-paper or cloth. The water must also be free from objectionable colour, odour and taste. It is sometimes necessary to rectify waters which are either too hard or too soft for the purpose in view, also in some cases manufacturers use distilled water for special purposes. Carbon dioxide is produced as a by-product in the combustion of coke in burning limestone to quick-lime, or from sulphuric acid and carbonates, or recovered as a by-product from fermentation processes. It is either made in a special gas-generator in the aerated-water factory or is purchased in a highly compressed or liquefied state in steel cylinders. In either case it must be free from objectionable taste. Carbonation furnishes in the finished beverage a gaseous pressure of from 40 to 80 lb. per square inch depending upon the type of product. High-pressure carbonation is used on ginger-ales, and is carried on at about 55° and impregnates the beverages with as high as four and one-half volumes of gas. Low pressure is used on fruit drinks, at about 40° to 42° and as low as one volume of gas may be employed.

THE SUGAR CONTENT

Sugar is specially manufactured for use in aerated-water production. It is highly refined by animal charcoal, no blue material having been employed to produce whiteness. Especial care is taken in the refining process to render the sugar free from sediment or scum when made into syrup. Artificial sweeteners, of which saccharin is the chief, are permitted in some countries, and such sweeteners are employed for special purposes, as in cases where sugar is undesirable because of its tendency towards fermentation, or in periods when sugar is expensive or difficult to obtain. Saccharin may be obtained in very high degrees of sweetening power, for example 550 times the sweetening power of sugar. In the United States the use of saccharin is prohibited by the U.S. department of agriculture and by most of the States. The acidifying materials commonly used in aerated waters are citric acid, tartaric acid, malic acid and phosphoric acid. These acids should be free from metallic and arsenical contamination.

Fruit Juices and Fruit Concentrates used for aerated or carbonated beverages are usually treated to eliminate the albuminous and pectinous matter and finally filtered, so that the finished beverages may be as clear as possible. However, there are also many natural fruit or combination of natural fruit and synthetic flavoured beverages with a cloudy appearance. Concentrated fruit flavours may consist of a blend of fruit juice and fruit oil, *i.e.*, from the peel of citrus fruits, and synthetic fruit esters, or a combination of two or more of these. Essential oils, *e.g.*, lemon, orange, limes, etc., are also employed for flavouring purposes, usually after they have been deprived of their insoluble terpenes and sesquiterpenes by fractional distillation. Vegetable extracts of either aqueous or alcoholic nature are prepared from herbs, roots and seeds for use in the production of ginger and herbal beverages. Mineral salts, *e.g.*, sodium bicarbonate, sodium sulphate, calcium chloride, sodium chloride, etc., are used in the preparation of table-waters. In some countries the use of small quantities of saponin bodies is permitted for the production of foam, such bodies being known as "froth-heading." Other substances which are used for this purpose are liquorice extract, for dark-coloured beverages, and various gums. Colouring matter is frequently added to aerated beverages. This usually takes the form of burnt sugar or caramel for brown-coloured drinks, and specially pure coal-tar colours for other beverages.

BOTTLING METHODS

The apparatus used in aerated water bottling is of a highly specialized nature, many improvements having recently been adopted. The bottles are washed by machines of various types, some of the larger being capable of cleansing 1,000 dozen bottles

A DEVICE FOR MEASURING SYRUP INTO AERATED WATER BOTTLES

The syrup enters from the bottom and ceases to flow when it reaches the air tube. The bottle, pressed against bottom nozzle, cuts off the supply tube and opens the discharge valve. The bottle when removed, closes the discharge valve and opens the supply tube and the syrup again enters

BY COURTESY OF (1, 6) THE GEO. J. MEYER MFG. COMPANY, (2) THE CROWN CORK AND SEAL COMPANY, (3) THE EDWARD ERNOLD COMPANY, (4, 5) THE MICHAEL YUNDT COMPANY

MODERN MACHINERY FOR THE MANUFACTURE OF AERATED OR CARBONATED WATERS

1. Cleansed and sterilized bottles being carried by automatic conveyors from a battery of three Meyer-Dumore Bottle Cleaners to the filling and crowning machines
2. A completely automatic multiple labelling machine, with a capacity of 120 bottles a minute, in use in Philadelphia
3. Automatic conveyor to the filling and crowning machines in general use throughout the United States
4. Special Standard Junior Combination Soaker Air Washer, with a cleansing and sterilizing capacity of 48 to 60 bottles per minute
5. Special Standard Junior Air Washer, eight bottles in width, automatically unloading cleansed and sterilized bottles
6. Meyer-Dumore cleansing and sterilizing machinery automatically loading empty bottles from boxes

per hour. The bottling units are capable of measuring into each bottle the correct amount of syrup, filling with carbonated water, sealing and labelling. The bottles used for aerated-water bottling are of four main varieties: (1) Codd's bottles, in which the bottle is sealed by means of a glass marble held against an india-rubber ring by the gas pressure; (2) crown cork bottles, which are securely sealed by a cork-lined metal cap clamped on to a shallow boss on the top of the bottle mouth; (3) screw-stoppered bottles, in which a lignum-vitae stopper screws down on to an india-rubber ring; and (4) swing lever stoppered bottles, in which a porcelain stopper is held down on an india-rubber seating by a strong wire lever acting upon the bottle neck. In the United States the use of crown cork bottles is almost universal. Aerated beverages are also largely sold in siphons, the gas pressure serving to discharge the container. Aerated waters are very simply produced on a domestic scale, in protected siphons, the aeration being accomplished by means of carbon dioxide contained in small steel cylinders.

Typical Compositions of various types of both table-waters and sweetened aerated waters vary widely, each manufacturer adjusting his product according to his judgment of popular taste and the type of water he is using. The following examples of dosage for the production of table-waters are given, taking soft or distilled water as a basis.

Soda-water.—Three and one-half oz. of a mixture of sodium carbonate 15 parts, magnesium chloride $6\frac{1}{2}$ parts, calcium chloride $6\frac{1}{2}$ parts, are dissolved in rogal. of water. This is strictly a table-water and should not be confused with the term "soda-water" used in the United States for flavoured beverages.

German Table-water.—Five and one-half oz. of mixture of sodium carbonate 10 parts, sodium chloride 10 parts, sodium sulphate 1 part, magnesium chloride 8 parts, calcium chloride 5 parts, are dissolved in rogal. of water.

The dosage employed in the preparation of aerated imitations of natural mineral waters (*see* MINERAL WATERS) is much heavier than in the preparation of table-waters, and many salts are included which have well-marked medicinal properties.

The basis of sweetened aerated waters is the syrup, which contains the acidifying material, flavour and colouring matter in addition to the sugar. Usually the syrup contains about 60% of sugar and is employed in the proportion of 1 to 2 oz. for bottles of from 6–12 oz. of finished beverage. The sugar content of carbonated beverages in the United States is from 6–17%, an average of 11%. This is a food value of approximately 80–100 calories for 8 oz. of beverage. The acidity of the syrup is equivalent to about 1% of citric acid, the acidity being adjusted to this strength when acid fruit juices are used. The colouring matter is varied according to the type of fruit which the drink represents. Most essences employed for flavouring aerated beverages are standardized so that they may be used to the extent of $1\frac{1}{2}$ –2 oz. per gallon of syrup. Thus in the preparation of a lime-juice syrup the following essence may be used in the proportion of 2 oz. per gallon of syrup: terpeneless West Indian distilled oil of limes 1 part, alcohol 60° O.P. 28 parts, distilled water 16 parts. In the preparation of beverages of a herbal or root-beer type, a smaller proportion of syrup is employed so that the beverages may not be too sweet. Also, a small proportion of foam-producing material may be employed.

Consumption.—In the United Kingdom, the Dominions and other countries where the sale of alcoholic beverages is permitted, consumption of aerated non-alcoholic drinks depends largely on weather conditions and on prices. Taking as example the United Kingdom, the sale of aerated beverages in many years has been restricted by the succession of wet, cold summers and by the high prices of such drinks consequent upon burdens being placed upon the industry by the Government. The census of production which was taken in 1924 yielded some interesting figures of the extent of aerated beverage production. Thus, in 1924, 36,004,000 gal. of table-waters, valued at £4,848,000, were produced, compared with 94,054,000 dozen bottles, valued at £4,046,000 in 1907; in the section non-alcoholic brewed drinks, as for example ginger-beer, herb-beer, etc., the value of the 1924 production was

£392,000, compared with £221,000 in 1907. As regards table-waters, the comparison of outputs is, to some extent, vitiated by the difference in units of measurement. When the difference in prices between 1924 and 1907 is taken into account it is clear that the output has declined. The same remarks apply to non-alcoholic brewed drinks. The exports of table-waters from Great Britain during 1924 amounted to 434,000 gal., valued at £165,000, and the imports to 878,000 gal., valued at £173,000. Thus only a small proportion of the total production was exported. As regards the imports of table-waters, these were almost wholly of an unsweetened nature, and they amounted to about 8% of the quantity of similar waters produced in the United Kingdom as shown by the reports of the commissioners of customs and excise.

There has been a tremendous increase in the consumption of "soft drinks" in the United States during recent years as a result of increased capacity for production enabled by inventions and improvements of manufacturing equipment, co-operation of the manufacturers through their trade associations with State and Federal authorities to prevent the use of inferior ingredients and to promote highest standards of sanitation in manufacturing and marketing, and to extensive advertising. The output of such beverages during each of three years 1924–26 displayed very marked increase. This is evidenced by the returns issued by the Crown Manufacturers' Association of America of the crown corks sold for beverage purposes. The total of such crowns sold for all beverage purposes in 1924, 1925 and 1926 was 45,693,057, 69,602,072 and 76,610,083 gross respectively. Statistics issued by the American Bottlers of Carbonated Beverages, the national trade association of the manufacturers of "soft drinks," show the total consumption in the United States of bottled carbonated beverages, exclusive of artificial mineral waters and non-alcoholic brewed drinks, in 1924, 1925 and 1926 was 8,000,000,000, 9,014,000,000 and 10,002,502,500 half-pint bottles respectively. The retail values were \$400,000,000 in 1924, \$450,700,000 in 1925 and \$500,125,125 in 1926.

AERIAL, an elevated wire or group of wires forming the principal part of a radio antenna of the open or "condenser" type. (*See* ANTENNA.) An aerial for the reception of programmes from broadcasting stations may consist of a single horizontal wire about 75 or 100 ft. long and elevated about 30 to 50 ft. from the ground. From the aerial, the lead-in wire connects to the receiving set.

AERIAL LAW, the law governing air travel. Aerial navigation is everywhere defined and limited by law. Some British and American jurists still find aviation law lacking in substance, since few precedents and no body of judicial decisions and opinions exist on the subject. With the presence, however, of national and international air statutes the law of aviation will continue to grow along with the development of commercial aeronautics. Speculation on the legal status of aeronautics arose even prior to the advent of mechanical flight. In 1900, about the time Santos-Dumont was making flights in his first power-driven air-ship, and long before heavier-than-air flight had been demonstrated by the Wright brothers, Paul Fauchille had anticipated legal problems growing out of aerial navigation, in his elaborate air code ("*Le domaine aérien et le régime juridique des aérostats*," *Revue générale de droit international public*, 1901). The International Juridical committee on aviation was organized in 1909 for the purpose of drafting an international air code. The rules of this code, although in a sense international, were suitable also for national or municipal codes. The committee continued its work at Paris in 1910, at Geneva in 1912, at Frankfurt on the Main in 1913. This organization has continued its work since the World War and in 1928 had a membership of 28 states in the League of Nations. Another international body, the Institute of International Law, in 1911 adopted a comprehensive code of air rules, applicable also to municipal regulation, covering nationality, registration and marks of identification. ("*Nouveau rapport à l'Institut de droit international*," Madrid, 1911, *Annuaire*, 1911.)

Legal concern before the war was chiefly centred upon the sovereignty of the air, reminiscent of the old controversy over the freedom of the seas. Speculation was based upon three main theories: (1) that, following the theory of *mare liberum*, the air

was free for all traffic regardless of nationality, with the qualification that the subjacent States could provide regulations for their own safety (Nys., *Annuaire*, vol. xxi.; Blüntschi, *Das moderne Völkerrecht*, pp. 22-26; F. Meili, *Das Luftschiff im internen Recht und Völkerrecht*; F. Despagnet, *Cours de droit international public* [1905]); (2) that the State had unlimited jurisdiction over its air space, a theory maintained chiefly by English and American jurists (Sir H. E. Richards, *Sovereignty Over The Air*, p. 27; H. D. Hazeltine, *The Law of the Air*, p. 39; Lycklama à Nijeholt, *Air Sovereignty*, pp. 13-14); (3) that State sovereignty was limited by servitude granting innocent passage for aircraft of all nationalities (J. M. Spaight, *Aircraft in Peace and the Law*; E. Catellani, *Le droit aérien*). The question was settled arbitrarily at the outbreak of the World War when all States asserted jurisdiction over their air space. Holland, Switzerland and the Scandinavian States repeatedly asserted their right of sovereignty, the Dutch enforcing this right by shooting down a German dirigible crossing their territory. (For compilation of notes exchanged by neutrals and belligerents on violations of neutrality by aircraft see *Seekriegsrecht im Weltkriege*, Reichs-Marine-Amts, 1919; also Spaight, *Air Power and War Rights*.)

National sovereignty over air space is now universally enforced. The International Flying Convention of 1919 provides for sovereignty, as do all international agreements and national laws. (British Aerial Navigation Acts of 1911, 1913 and 1920; Franco-German Agreement of 1913; International Aerial Agreement between Great Britain and Switzerland; U.S. Air Commerce Act of 1926.) The right of innocent passage has been accepted, in part, by all nations, but only by treaty. The International Flying Convention provides for contracting states in this respect.

National municipal law also antedates the World War. National acts regulated aerial navigation in France, Germany, Great Britain and Italy. In America the States of Connecticut and Massachusetts had enacted State laws. Air rules, however, are based primarily upon the regulations laid down in the International Flying Convention of 1919. (See P. Cogliolo, *Codice aeronautico*, 1927; M. Sudre and M. Peyrillier, *Répertoire de l'aéronautique et des transports aériens*, 1923; *Treaties, Conventions, International Acts, Protocols and Agreements between the United States and other Powers*, vol. iii., p. 3,768.) (M. W. R.)

The parties to this convention which begin by affirming the sovereignty of each State over the air above its territory are the British Empire, Belgium, Bulgaria, Chile, Czechoslovakia, France, Greece, Italy, Japan, Persia, Poland, Portugal, Rumania, the Saar Territory, the Serb-Croat-Slovene State, Siam and Uruguay. This principle affirmed, the convention goes on to provide for freedom of innocent air passage over the territory of the contracting States for each party to the convention, provided the conditions laid down in it are observed. Such freedom of passage does not apply to "prohibited areas" which States may desire for military reasons to close to all private aircraft, including those in their own territory.

The "nationality" of an aircraft is made to depend upon the country in which it is registered; to be registered in a particular State the aircraft must belong to a national of that State or to a company of which the chairman and two-thirds of the directors possess that nationality. Double registration is prohibited. Every aircraft engaged in international navigation must possess a certificate of airworthiness issued or rendered valid by its State of nationality, and the pilot and other members of the crew must be provided with certificates of competency and licences similarly issued or validated. The documents (certificates, licences, log-books, passenger lists, manifests) which aircraft must be provided with are laid down.

Foreign aircraft may be required to land at aerodromes fixed by the State whose territory they enter; and each State has the right to reserve in favour of its national aircraft the carriage of persons and goods for hire between any two points in its territory. Provision is made for the rendering of assistance to aircraft in landing or in distress, for the application, to aircraft wrecked at sea, of the principles of the maritime law of salvage, for the use of aerodromes at a common tariff of charges, and for certain other

matters. The convention is not applicable to military aircraft nor to State non-military aircraft employed on customs and police service; other State aircraft; e.g., postal, are subject to its provisions. A military aircraft is defined as one commanded by a person in military service detailed for the purpose, and such an aircraft may fly over another contracting State's territory only in virtue of a special authorization.

Rules in regard to the marking of aircraft (to show nationality and identity), certificates of airworthiness, log-books, lights and signals, "rules of the road," licensing of personnel, aeronautical maps and ground markings, the collection and dissemination of meteorological information, and customs procedure, are contained in annexes to the convention, which have been modified from time to time by the International Commission for Air Navigation.

International Commission.—A permanent International Commission for Air Navigation, composed of representatives of the contracting States, is established and charged with certain powers, including the amendment of the annexes, the receipt or initiation of proposals to amend the convention itself and the inter-communication of information affecting air navigation, etc. The office of the secretary-general of the commission is at 20, Avenue Kléber, Paris. The convention may be denounced by one year's notice. States which did not take part in the World War may adhere to it at any time; those which took part in the War may adhere under certain specified conditions. The Commission issues half-yearly a *Bulletin* containing the Convention of 1919 and its annexes revised up to date, and bilateral conventions.

Other Arrangements.—A number of important Powers, it will be seen, are not as yet parties to the Convention, and international air traffic is regulated, so far as they are concerned, by a series of special agreements between themselves and with other States; e.g., the Convention between France and Germany, May 22, 1926. The terms of these agreements are in general conformity with those of the convention. The obstacle to a more general acceptance of the convention has been, first, the provision therein forbidding contracting States to permit, except by special and temporary authorization, the flight above their territory of the aircraft of non-contracting States; secondly, the "weighted" vote which was allowed to the British empire, France, Italy and Japan. Protocols of amendment of both these provisions have been signed but, not having been ratified by all the parties, are not yet in force.

The convention of 1919 does not bind the contracting parties as belligerents or neutrals (though it would continue to apply in war as between two neutrals), and an attempt to frame a corresponding code for war was made at The Hague in 1923. A commission of jurists, representing the United States, Great Britain, France, Italy, Japan and The Netherlands, under the chairmanship of John Bassett Moore, drew up rules which, though they have not been embodied in a convention, are a valuable indication of international opinion, as it stood in 1926, upon the law of air warfare.

Municipal Legislation which has been passed to regulate internal flying and to give effect to the international obligations of each country under the convention of 1919, or the separate bipartite agreements, is contained in laws, decrees, ordinances and regulations of many different kinds. It is of great volume and an indication of its general scope is all that can be attempted. One usually finds in such legislation (*lato-sensu*) provisions for ensuring the safety of air navigation as affecting both air travellers and the general public; provisions, that is to say, for registration and certification of aircraft, licensing of personnel, inspections and tests precedent to such certification and licensing, maintenance and overhaul and renewal of certificates and licences, inspection, licensing and use of aerodromes, carriage of explosives and arms, dropping of articles in flight, jettison of cargo, minimum height of flight over populated areas, investigation of accidents and so on. For defence reasons "prohibited areas" are usually defined, and in many cases corridors of entry for foreign aircraft are prescribed as well as the general conditions on which such entry is allowed; and the carriage of radio apparatus and cameras is usually restricted. Conditions for the grant of concessions for the operation of com-

mercial air lines and the establishment of international airways are occasionally included. Penalties (fine, imprisonment, suspension of licence) for the infringement of the rules are invariably laid down.

Liability for Damage.—Liability for damage occasioned by aircraft to persons or property on the ground appears in many of the codes. In the absence of special provision the liability of the owner or pilot would be dependent ordinarily on proof of actual negligence or intention. Proof would often be very difficult to obtain and hence it has generally been considered equitable to impose upon the owner or pilot an absolute liability to pay compensation for all such damage, save in so far as he can show that the person damaged was himself to blame. It is also sometimes provided that the owner of an aircraft, or the organizers of an air navigation company must cover themselves by insurance against possible claims for compensation or else must deposit security sufficient to cover their liability.

Occasionally it is provided that legal relations between parties on board a foreign aircraft in the air are governed by the law of the aircraft's nationality; *i.e.*, the country in which it is registered. The French law qualifies such a provision by adding that a crime or misdemeanour committed on board a foreign aircraft is within the competence of the French courts, if the guilty party is a French national, or if the aircraft lands in France after the occurrence of the offence. (J. M. S.)

Conference of 1925.—In Oct. 1925, at a conference in Paris of the European and certain other Governments, a draft convention was framed to determine the responsibility of carriers by air. This corresponds to the Berne Convention of 1890 on transport by rail. An international committee of experts is to continue the work of this first conference, and to study a series of questions, connected with unification of private law, of the very greatest practical importance for the development of air traffic, such as damage caused by aircraft to property and persons on the ground, compulsory insurance, establishment of air registers, rights of property and ownership, and mortgages in respect of traffic by air. (H. H. L. B.)

United States.—In contrast with European activity no national law existed in the United States until the passage of the Air Commerce Act of 1926. Until then such ordinary regulations as those governing licensing and inspection of shipping and railroads were lacking for air traffic. Pilots without licences flew aeroplanes which had never been inspected, resulting in hundreds of accidents. With the exception of the government-operated air-mail no air-lines operating on regular schedules were in existence. Aviation was regarded more as a hazardous sport than as a means of communication and transportation. Accidents were caused by defective machines, errors in piloting, lack of terminals, routes and weather data. A Government report attributed 91% of all the accidents to "inexperience and the use of cheap and unsafe equipment."

Uniform air regulation in the United States was complicated by the independent action of many of the individual States. In 1926 there were 26 State air laws. (For State laws in the United States and for the Federal Air Commerce Act see C. Zollman, *Law of the Air*, 1927; R. W. Fixel, *The Law of Aviation*, 1927.) In a flight of 500 m. a machine might come under the jurisdiction of six States each with a separate and perhaps conflicting set of air rules. Exclusive national control was improbable, since this would have necessitated either a constitutional amendment or the voluntary submission on the part of the 48 States to a national air law. Concurrent control alone was possible and uniformity of regulations remained dependent upon the action of the different States. A movement for uniformity had already appeared previous to the enactment of the national air law. The California air statute thus provided that the enactment of Federal air legislation would automatically void its local air law. The Uniform State Law of Aeronautics, adopted already by ten States and Territories, provides that "this act shall be so interpreted and construed as to effectuate its general purpose to make uniform the law of those states which enact it, and to harmonize, as far as possible, with Federal laws and regulations on the subject of

aeronautics." The Federal enactment in 1926 of the Air Commerce Act, supplemented by the Uniform State Law, will tend to bring about uniformity if not exclusive Federal control. The Air Commerce Act follows mainly the rules of the International Flying Convention. The act provides for a Bureau of Civil Aeronautics in the Department of Commerce. This bureau, under an assistant secretary of commerce for air, has charge of Federal inspection of aircraft, crews and aerodromes and the establishment and enforcement of air navigation rules. It also furnishes aids to air navigation by approving and charting air routes, establishing air light-houses and signal stations, furnishing suitable weather reports and providing at the Government fields, in cases of emergency, supplies and repairs at their fair market value. Special provision is made for trials giving the individual complete freedom to test and fly new inventions, no matter how freakish, so long as they do not endanger the public safety. No machine, however, is permitted to carry passengers unless it has been inspected and licensed as a public carrier. European air laws carefully protect the public against the unproved freak machine but they in no manner prohibit the building and testing of any type of craft, from helicopters to tail-less and wingless machines.

Safe air travel will be the preliminary aim of the air board. Public confidence in air travel must be created. To accomplish this air accidents must be decreased, if not eliminated, to a percentage lower even than railroad casualties. In Germany a rigid system of inspections and licensing has helped to cut accidents to a negligible ratio. The following experts' list of "six requisites for safe flying," will serve as a basis for the new air regulations: (1) A machine sound aerodynamically and structurally; (2) a reliable engine of sufficient power; (3) a competent conservative pilot and navigator; (4) airports and emergency landing fields, sufficiently close together to insure gliding to safety; (5) nationwide weather forecast, specialized and adapted to the needs of flying; (6) adequate charts of air routes.

AERIAL NAVIGATION, the science of ascertaining the position of an aircraft and setting its course in a designed direction.

The possibility of applying the methods and instruments used for the older science of maritime navigation to navigation in the air, has naturally been thoroughly explored, but certain fundamental differences need to be allowed for. The speeds of aircraft are several times greater than those of ocean liners; the wind velocities are usually much greater and far less consistent than ocean currents; further, the weight of navigating instruments which can be carried in an aircraft, and the space available for their use are limited.

The most elementary method of navigation is the recognition, either from maps or from previous experience, of the country over which the aircraft is flying; for this purpose, maps have been made which give prominence to railways, rivers and other objects conspicuous from aircraft.

DEAD RECKONING NAVIGATION

The basic method of navigating an aircraft is known as dead reckoning (D.R.); all other methods, such as wireless direction finding or the determination of the altitude of heavenly bodies, serve only to check the D.R. position. Dead reckoning necessitates that a record shall be kept of the speed of the aircraft over the ground and the "track," the latter being the actual direction along which the aircraft is passing over the ground. These values

may be obtained from a knowledge of (a) the speed and direction of the wind, derived either by observation from the aircraft or from meteorological reports; (b) the true speed through the air, obtained by correcting the air-speed indicator for height; and (c) the compass course.

If a vector triangle be drawn such that one side represents (a) above, and another side represents (b) and (c), then the length

FIG. 1.—POSITION OF INSTRUMENT BOARD IN AEROPLANE COCKPIT

Ordinarily there is only one instrument board in an aeroplane. The dual installation here shown is in an instrument testing plane. In the forward cockpit the instrument board consists of round indicators. In the after cockpit vertical indicators are shown

of the third side represents the ground speed and its direction the track of the aircraft over the ground. The ground speed is determined by noting the time taken for a ground object, viewed through a "sight" set at the appropriate position on a vertical bar calibrated in terms of height, to appear to traverse the distance between two timing beads fixed on a horizontal wire which is set along the track of the aircraft. The distance between the two timing beads is made to represent a certain distance on the ground (usually $\frac{1}{2}$ m.) over which the aircraft passes in the observed time.

The angle between the fore and aft line of the aircraft and the track is called the drift angle; it may be determined by observing the direction in which an object on the ground appears to move with reference to the fore and aft axis of the aircraft. If the aircraft were flying directly up or down wind, the drift angle would be zero. The true air speed being known, the wind speed and direction may be found, without timing a ground object, by observing the drift angle on two different compass courses, preferably separated by a fairly large angle.

Graphical construction cannot conveniently be employed in the limited accommodation afforded by an aeroplane cockpit and it is much preferable to solve the vector triangle by instrumental means. Moreover, it is but natural that, where possible, the means for observing ground speed and drift, and the mechanism for solving the vector triangle should be incorporated in one instrument.

Instruments and Methods.—The following are the most important of the instruments used for D.R. navigation. Each enables the ground speed to be determined in the manner described above, and incorporates means whereby the vector triangle may be solved on the instrument itself. They differ somewhat, however, in the method by which the drift is determined. (See fig. 2.)

The Aero Bearing Plate.—In this instrument the drift angle is determined by sighting on a ground object ahead of the aircraft and turning a horizontal drift bar so that the ground object appears to move along the bar.

The Wind Gauge Bearing Plate.—This instrument enables the drift angle to be determined by taking tail bearings of objects over which the aeroplane passed some minutes previously. These observations cannot conveniently be taken by the pilot and a navigator must be carried.

The Course-Setting Sight (Wimperis).—In this instrument the drift angle is determined by sighting ahead. The incorporation of a compass and a link mechanism renders the operation of the instrument to some extent automatic.

The methods of determining the height and speed of aircraft are dealt with elsewhere (see ALTIMETER).

The desiderata of any type of aircraft compass are: (a) that there should be a datum line indicating a known direction; (b) that a restoring force shall be set up if the direction of this line be altered by some agency external to the system; and (c) that the oscillations natural to the system after a disturbance shall be damped. The magnetic compass is particularly suitable for aircraft, since these requirements can be provided without prejudicing lightness and simplicity (see COMPASS and EARTH INDUCTOR COMPASS).

Altimeters.—The most convenient method of determining the height of an aircraft above the ground is by the use of an altimeter, a form of aneroid barometer (*q.v.*). All altimeters are, therefore, set at zero when the aircraft leaves the ground, and they are calibrated in accordance with a standard atmosphere, which has been adopted internationally. The standard atmosphere assumes that, at sea-level, the temperature is 15° C and that the barometric height, reduced to 0° C, is 760 mm. of mercury. The decrease of temperature with increase of height is assumed to be 6.5° C per km. Altimeters so calibrated are usually accurate to within from 2% to 3%. For some purposes, however, a greater accuracy is necessary; this can be achieved by applying a correction obtained from a knowledge of the temperature on the ground and at the operating height. Carefully designed altimeters so corrected are capable of an accuracy of the order of 1%, so long as the conditions of atmospheric temperature and pressure do not vary. An altimeter, however, is quite unable to distinguish a change

these poles its values are too small to afford the directive force which a compass must have. The directive properties of a gyroscopic compass also decrease as the polar regions are approached, being zero at the earth's geographical poles. An interesting attempt to solve the problem of observation of the sun, has resulted in the Goertz sun compass. In this instrument an image of the sun is projected on a ground glass screen when the aircraft is flying on a given course; a rotation of the optical system about a vertical axis once in 24 hours provides that the image is maintained on the screen unless a change of course is made. In practice, the pilot would set the sun compass to the desired course and turn the aircraft until the sun appeared on the ground glass screen; he would then steer by this sun image.

POSITION FINDING

The utility of dead reckoning navigation is limited by the need of at least occasional observation of the ground, and, unless it is possible definitely to recognize some landmark from time to time, the method is subject to accumulative error. In fog, or when an airman is flying above cloud, the ground is not visible and an alternative means of navigation must be provided. One such means, direction finding by wireless (*see* WIRELESS TELEGRAPHY) is still the subject of experiment; while another, navigation by astronomical observation, has been used at sea since the 16th century.

Wireless Direction Finding.—All methods of direction finding by wireless have one underlying principle. If a rectangular coil, capable of symmetrical rotation about a vertical axis, be so placed that the plane of the coil is at right angles to the direction from which the wireless waves are transmitted, no current is set up in the coil; in any other position an oscillating current flows having a maximum value when the coil is set "edge on," *i.e.*, when the two vertical sides and the sending station are in the same vertical plane. If, therefore, the coil be rotated until the current is observed to be a maximum or a minimum, the bearing of the sending station can be determined. In practice, telephonic detection is employed and the position of the minimum or zero signal is preferred to that of maximum strength owing to the much greater sensitivity obtainable. For ground reception the Bellini-Tosi system is usually employed; this consists of two small fixed coils, mutually at right angles, each being connected to an aerial loop, and a rotatable search coil symmetrically arranged with respect to the two fixed coils.

Ground Station D. F.—This is the only method at present regularly employed on commercial air routes. The aeroplane carries transmitting and receiving sets, and calls for its position. Two or more ground stations observe the bearing of the aircraft, and one of them plots the position on a chart and communicates the information to the aeroplane. This method is fairly satisfactory for day use, but reception by a ground station at night is subject to inaccuracies known as "night-effects." Moreover, it is for many reasons desirable that the position should be determined by the aircraft itself and not by a ground station. For this purpose it is sufficient if the ground station transmits signals and the aircraft carries a receiving set, together with means for detecting the direction of the wireless waves. The following are various modifications of this system; each has been the subject of experiment but none is yet in regular use.

Wing Coil D. F.—This method has undergone successful air tests and can be operated by the pilot. Two sets of coils mutually at right angles are fitted in the aeroplane wings and connected to a receiver. One set, the main coils, is directed fore and aft, and the other, the auxiliary coils, is athwartships. When the aircraft is headed toward the sending station the auxiliary coil receives no current but the main coil receives maximum energy. Under these conditions reversal of the auxiliary coil has no effect upon the signals received by virtue of the current set up in the main coil. If now the aircraft be turned so that its fore and aft axis is no longer toward the station, a current is set up in the auxiliary coil, and alternate reversals of the auxiliary coil will, under these conditions, result in unequal strengths of signals; the aircraft must then be turned until equality of signal strength is obtained. The

disadvantage of the method is that it is convenient only when the sending station is the objective or lies on the desired track of the aircraft; moreover, the time taken to fly to the sending station when navigating by wing coils will not, in general, be the shortest possible time, though this is not a very serious objection. The method cannot conveniently be employed to determine position; "homing" by wing coils merely ensures that the aircraft will eventually reach the sending station.

Fuselage Coil D. F.—An alternative method is to use two coils mounted on frames suitable for fitting in the fuselage of the aircraft; these coils are mutually at right angles and may be rotated about a vertical axis. With this arrangement the bearing of a sending station may be obtained, without change of course, by the method described for wing coils. Two or more such bearings on different sending stations, of known positions, would enable the position of the aircraft to be determined. This method necessitates special apparatus and requires the attention of a skilled observer.

Directional Transmission.—In this method the ground station apparatus consists of a fairly large loop which rotates at a speed of about one revolution per minute. No energy is radiated in a direction at right angles to the plane of the coil, and by "tuning in" to the station and observing the time between two consecutive points of silence, the exact speed of rotation can be estimated. Further, if the station emits a distinctive signal when the loop is directed, say, due north, the bearing of the sending station can be calculated by observing the time interval between the distinctive signal and the next zero signal. In practice it would be necessary to use two distinctive signals, preferably 90 degrees apart.

Navigation by Astronomical Observation.—The determination of the position of an aeroplane by astronomical observation is attended by many difficulties and is hardly likely to be employed on a developed air route along which it is convenient to erect wireless beacons. For long distance pioneer flights over undeveloped country and for trans-Atlantic flights, astronomical observation remains the only method of checking the D.R. position. The principles employed are essentially those used for maritime navigation (*see* NAVIGATION), but both the accuracy needed and the accuracy attainable are considerably less on aeroplanes. Determination of the altitude of a heavenly body necessitates either that the horizon shall be visible, or that the true horizontal or vertical be otherwise known. The horizon is often indefinite from an aircraft, and this fact has led to the development at the Royal Aircraft Establishment, Farnborough, of an instrument known as the Bubble Sextant.

The R.A.E. Bubble Sextant.—The image of a bubble, contained in a chamber having a spherical glass cover, is observed by reflection from a pentagonal prism and subsequent transmission through a collimating lens and an index glass. The optical distance of the bubble from the lens and the radius of curvature of the glass cover are both chosen to be equal to the focal length of the lens. This arrangement provides that if an image of the sun, obtained by reflection from the index mirror, is brought into coincidence with the bubble image and the instrument is rocked in the hand, the bubble remains in focus, and bubble and sun appear to move together. When measuring the altitude of a star it is more convenient to observe the bubble image by reflection from the under-side of the index mirror and the star by direct transmission through the mirror. The bubble is, of course, subject to displacement if the aircraft experiences an acceleration which is not truly vertical, and, in practice, an average of ten readings is taken.

NAVIGATION IN FOGS AND AT NIGHT

The safety of an aeroplane flying near the ground depends largely upon the pilot's ability to maintain, within limits, an even keel, normally not difficult; but in fog, when visual connection with terrestrial and celestial objects is not possible, means should be provided to enable a pilot instantly to recognize any involuntary change of course. It is not at first obvious why the natural gravitational force is not a sufficient indication of the vertical.

When an aircraft is turning, however, it is flying on a curved path and the centrifugal acceleration, which acts at right angles to the direction of flight, needs to be considered. It is naturally not possible for a bubble level to distinguish acceleration due to one cause from that due to any other, and the liquid in the level is acted upon, not by the earth's gravitational force alone, but by the resultant of the centrifugal force and the earth's gravitational force. This resultant acts at right angles to the "floor" of the aircraft and the bubble consequently seeks, not the true vertical, defined by gravity, but the apparent vertical, defined by the direction of the resultant of the accelerations. If, therefore, the aircraft executes a banked turn in flight, the bubble remains in the centre of the level and does not indicate a change of course. In fog or cloud a pilot may be unaware that his craft is turning and the magnetic compass affords him little aid, since, as already explained, it is unreliable, under these conditions. The need for an instrument which will indicate that the aircraft is changing course has led to the development of the gyro turn indicator.

The Gyro Turn Indicator.

—The gyro turn indicator provides a pilot with a continuous indication either of the maintenance of straight flight or, if the aircraft is turning, of the direction and approximate rate of the change of course. The action of the instrument may be understood by referring to fig. 3. A

FIG. 3.—DIAGRAM ILLUSTRATING PRINCIPLES OF A TURN INDICATOR. The Turn Indicator enables a pilot to know when he is turning and is of particular use in clouds and fog and at night.

gyro wheel, *a*, rotates about an axis, *b c*, which is horizontal in level flight, and is usually arranged to be athwartships on the aircraft. The frame carrying the wheel and its axle is free to rotate about another horizontal axle, *d e*, at right angles to *b c* (i.e., in the fore and aft line of the aircraft). The axle, *d e*, supports the wheel and the inner frame in an outer frame which is fixed to the aircraft. If the aircraft changes course, the whole system is rotated about a vertical axis, *f f*, and, in accordance with the laws governing the behaviour of a gyroscopic system (*q.v.*) the wheel and the axle, *b c*, commence to rotate about *d e*.

This rotation, which is known as precession, is controlled by springs, *g g*, so that the deflection of *b c* is a measure of the rate of change of course and so that the axle, *b c*, may return to a horizontal position when the aircraft is again flying on a straight course. The deflection of *b c* may be indicated to the pilot by any suitable means. The instrument has proved of the greatest use for flying in fog or cloud; it has been developed in a number of countries, but all types depend upon the principle outlined above and differ chiefly in the methods of indicating the turn and the Reid turn indicator (fig. 4) is one type of the instrument. It employs two rows of electric lamps, each row consisting of four red and four green lamps on each side of a central white lamp. The upper row is controlled by the position of mercury in a U-tube and indicates whether the aircraft is correctly banked. The lower row is controlled by the gyro and indicates the rate of turn. To maintain straight flight the pilot must fly so that no coloured lights are visible.

The Gyro Rudder Control.—Another device, making use of the gyrostatic principle, is the gyro rudder control developed at the Royal Aircraft Establishment, Farnborough. The primary object of this instrument is to relieve a pilot from the strain consequent upon the maintenance of a straight course for a long period of time. The principle is shown in fig. 5. The gyroscopic system consists of a rotor, *a*, mounted in an inner gymbal ring, *b*, which is pivoted about a horizontal axis to the outer gymbal

ring, *c*. The latter carries a pin, *d*, and rotates about a vertical axis, thus operating a valve by means of the lever, *e*. The system is mounted on a vertical pivot, *f*, and two ratio arms, one attached to the false rudder bar and one to the gyro box, engage at *g*. If the aircraft turns, for example, to starboard, air is admitted to the port cylinder, shown in fig. 5, and the starboard cylinder is put into communication with the atmosphere. The pistons consequently move and operate the false rudder bar pivoted at *h*, which in turn operates the pilot's rudder. Movement of the false rudder bar, however, causes a rotation of the gyro box on its pivot, *f*; the valve then closes and the rudder bar returns to its neutral position.

Landing in Fog.—The solution of the problem of effecting a safe landing through several hundred feet of fog is of vital importance to the future of aviation. The problem is one of providing that the pilot of a rapidly moving aircraft shall be able to descend into a fog and, the ground being invisible, shall have an accurate knowledge of his height and the location of suitable landing ground. The nearest approach to success has been achieved in England, where the prevalence of fog brings the problem into particular prominence; efforts have been made in two different directions, the leader cable system and neon lighting; these should be most effective when used in conjunction. A third method is that of the Behm height-finding apparatus (fig. 6).

The Leader Cable System.—In the leader cable system, a cable laid just beneath the ground and excited by alternating current, produces a magnetic field above the cable, consisting of circular magnetic lines of intensity varying approximately inversely as the height above the cable. Vertically over the cable the lines are horizontal, and if instruments are carried enabling this condition to be detected, the pilot will be able continuously to fly vertically over the cable and by gradually decreasing his height, to effect a landing. The position of the track most suitable for landing can be indicated to the pilot by, for example, an auxiliary cable laid along a part of one of the parallel sides of the track. A leader cable has been laid down at the Royal Aircraft

FIG. 4.—THE REID TURN AND BANK INDICATOR

Consisting of an upper and lower row of four red (port) and four green (starboard) electric lamps on either side of a middle white lamp. The upper row indicates the amount of bank, the lower, the rate of turn. If the course is straight no coloured lights will be visible to the pilot.

Establishment, Farnborough, consisting of two straight sections, each about 1 mile in length, connected at the ends by semi-circular bends of about $\frac{1}{2}$ mile radius.

The instruments carried on the aircraft consist of two search coils oriented in such a manner that when the aircraft is vertically

over the cable the resultant electromotive force induced in them is zero, but if the aircraft departs from the desired course, the E.M.F. induced in one coil is greater than that induced in the other and the instrument indicates this condition. The height is determined by a suitable calibration of an instrument which measures the intensity of the magnetic force.

Full scale trials have proved that the operation of the scheme should be practicable, and it has been demonstrated that an aircraft can fly round the track and obtain indication of height purely by use of the instruments carried on the dashboard.

Neon Lighting is particularly suitable for landing in fog owing to its distinctive colour, and to the fact that long "lanes"

FIG. 5.—R.A.E. GYRO RUDDER CONTROL. SHOWING PARTS
This apparatus automatically controls the rudder, relieving the pilot from the strain consequent upon maintaining a straight course and enabling aircraft to fly safely through clouds

of illumination can be provided. Neon tubes have been laid on Croydon Aerodrome and it has been shown that the resulting red glow on the top of a moderately thick fog can be seen at a considerable distance when the aircraft is flying above the fog. When actually in a dense fog, however, the pilot would only see the neon tubes when about 50 ft. above them. However, neon lighting would be of great assistance during the last few seconds of landing.

Flying and Landing at Night.—Navigation at night presents far less difficulty than do flying and landing in fog. There will usually be no difficulty in navigating by D.R. methods, and the problem of night landing is mainly one of supplying sufficient and suitably placed illumination at aerodromes. It is probable that a night-operated air route will have a number of light beacons at suitable distances apart and, unless visibility is very poor, the pilot's task will be merely to fly from beacon to beacon.

The United States have a lighted airway of 1,900 miles from New York to Rock Springs, consisting of a number of terminal aerodromes about 250 miles apart, each having two electric arc beacons, of 500,000,000 candle-power each, one circling the horizon every 20 seconds and the other providing flood lighting for landing purposes. In addition there are emergency fields about 15-30 miles apart, each provided with a light beacon; acetylene gas beacons have been installed every three miles over a considerable proportion of the route. A thousand million candle-power beacon near Dijon, France, having a normal range of about 300 miles has been built mainly to assist aircraft flying at night between Paris and Algiers.

An interesting method of facilitating night landing, known as the Hoenig circles, originated in Germany. The installation con-

sists of two vertical lighted circles of different sizes, placed one behind the other, mounted on a trolley and so arranged that the common axis of the circles indicates the direction of landing. The pilot manoeuvres his craft until he observes two concentric circles; by preserving this orientation of the circles a correct landing can be effected.

Navigation of Airships.—Whilst the principles underlying the navigation of aeroplanes apply also to the navigation of airships, the foregoing description of navigational methods and of the peculiar advantages and disadvantages associated therewith applies chiefly to heavier-than-air craft.

An airship is much steadier than an aeroplane, and instruments, particularly the magnetic compass, are more reliable. Under suitable conditions, astronomical observation can be taken and reduced without difficulty and the accommodation for wireless equipment is greater than in an aeroplane. It will be seen that the conditions obtainable for airship navigation are substantially those employed in maritime navigation. It is important to note, however, that the navigation of airships over long distances will render the availability of accurate meteorological information of primary importance, since an airship, unlike an aeroplane, can land or "anchor" only on prepared aerodromes or masts.

AERODROME, AIR PORT or AIR STATION. An aircraft can land and take-off safely in any large open space, but an organized and equipped aerodrome is required for regular flying. Just as railways must have depots and stations of varying kinds and ocean-going liners must have harbours and docks, so is it necessary for aircraft to possess aerodromes.

Provision of Aerodromes.—On a recognized air route for the operation of land machines, such, for example, as that from London to the Continent, a series of aerodromes is provided at an average distance apart of 25m. and these are classified, according to the purpose which they serve, as terminal aerodromes, aerodromes, landing grounds, and emergency landing grounds. These are situated at Croydon (terminal aerodrome), Penshurst (landing ground), Marden (emergency landing ground), Lympne (aerodrome) and Littlestone (emergency landing ground). Lympne and Littlestone are approximately 5m. apart, and the reason for the existence of the latter, which is situated about sea-level near the coast, is that the former, being on high ground formed by the cliffs overlooking Hythe, is liable to be obscured by low clouds which drift in from the sea. Of the above, both Croydon and Lympne are provided with customs facilities and in consequence are further classified as "customs aerodromes."

The Terminal Aerodrome.—The ideal terminal aerodrome should be close to the heart of the city which it serves; but in the event of this being impossible it should be provided with good communications by road, rail, train or bus. Consideration must be given to adverse meteorological conditions, especially fog.

The ideal layout for an aerodrome is to place the main block of buildings, surrounded by the hangars, in the centre of the aerodrome so that unnecessary taxiing is avoided. Such an

FIG. 6.—THE BEHM HEIGHT-FINDING APPARATUS

Low altitudes are measured by timing a sound wave emitted from the airship and reflected back from the ground. The height is observed by watching the movement of a spot of light on the scale

arrangement also keeps the landing area clear of interference from aircraft manoeuvring on the ground. One drawback is that it is necessary either to have an access road across a part of the ground used for flying, which would be both dangerous and inconvenient since it would tend to cause delays; or else to construct a tunnel road under the aerodrome, a very costly item. From an operational standpoint, the advantages of such a system far outweigh the disadvantages; but the main obstacle to its adoption is the large area of ground that would be required, since it must be of sufficient dimensions to give a clear take-off run in any direction. Consequently it is the normal practice to group all the buildings

PHOTO BY THE GERMAN RAILROADS INFORMATION OFFICE

TRANSFERRING PASSENGERS FROM AEROPLANE TO BUS FOR TRANSPORTATION TO CITY SERVED BY THE AERODROME

together on one side of the aerodrome where adequate approach facilities by road exist.

The site should afford at least 1,000yd. run into any wind. The soil should be light, the land level and for choice a plateau. The land immediately surrounding the site should be free from obstructions.

Aerodromes for the use of flying boats or seaplanes have an open-water site from which to depart and on which to alight, and slipways leading from this water site to the hangar accommodation and to the departure and arrival platforms.

Equipment.—A terminal aerodrome normally is equipped with hangars for the housing of aircraft, workshops, bonded and technical stores, administrative and booking offices for the companies operating services from the stations, as well as for travel and transport agencies, petrol and oil companies, etc. In addition, facilities frequently exist for the customs and for the immigration authorities. Aerodromes are further provided with wireless and meteorological facilities, together with government personnel to operate them. Illuminating beacons for the assistance of aircraft flying by night, and some device for indicating the direction of the wind both by day and by night, are installed. Accommodation is provided for an official belonging to the Government aeronautical inspection department, whose duty it is to ensure that aircraft are being properly maintained; for traffic workers to carry out portage duties and assist in handling machines on the ground; and for the officials appointed by the government for controlling air traffic, the aerodrome, and the government personnel employed there.

Landing Grounds.—Landing grounds may, or may not, be equipped with hangar accommodation, but are normally provided with beacons and wind indicators. Telephones are generally installed, but no personnel other than a caretaker will be found there. Emergency landing grounds are rarely equipped with any form of hangar accommodation and may, or may not, have beacons and wind indicators. Each of the stations on the route to the Continent, with the exception of Marden, shows its name in large capital letters and the good landing area is indicated by automatic red flashing lamps.

Airship Station.—Aerodromes for the use of airships will in general be provided with all the facilities outlined above as requisite for the operation of land aircraft, but in addition will be equipped with a mast at which an airship can be moored, and a plant for the production of the gas required for inflating the ship.

Under normal conditions an airship will only be berthed in a hangar for purposes of overhaul or repair; at other times it will be moored at a mast, which is a steel structure approximately

200ft. high. The head of the mast is fitted with a receiving arm with which a cone on the bow of the airship engages, providing free movement in any direction. The mast is supplied with lifts or elevators for the crew, passengers, goods, etc., and with pipes for the supply of gas, fuel and water. A passenger mounting this lift will find himself in a compartment from which a covered way leads into the nose of the airship and thence to the passenger accommodation.

The New London Terminal Aerodrome.—It became necessary in 1928 to enlarge and rebuild the London Terminal Aerodrome at Croydon. The accompanying plan shows the enlargement and alterations that were decided on. The new aerodrome possesses a maximum run north and south of 1,350yd. and east and west of 1,450 yards. The old buildings were being demolished in 1928 and new ones erected on the east side. The road on which the old buildings stood has been diverted so as to form one of the boundaries. The two hangars have a floor area of 90,000 sq.ft. Offices, stores, workshops, etc., with an area of 36,000 sq.ft., are included in the annexes to these hangars.

The main terminal block provides accommodation for the control staff, the operating companies, and for customs and immigration authorities. Passengers arriving and departing will pass through a central hall in which the booking hall and various waiting rooms are located.

A control tower has been built on the top of the main terminal block. Here an officer assisted by a wireless operator is constantly on duty and is directly in touch with pilots in the air. As machines report their position the control officer marks them on a map and issues any directions and warnings which may be necessary. He also controls the movements of aircraft about to take-off or coming in to land.

Night Lighting.—Adverse weather may compel the pilot to land just after dark, and a landing in fog may sometimes be unavoidable. Adequate lighting facilities must therefore be provided to take care also of regular night flying, which will undoubtedly be organized on the cross-channel routes in the near future.

Beacons of special design are required to meet the needs of the aerial navigator. Croydon possesses a Neon Beacon which is said to have remarkable fog-piercing properties and is visible on clear nights as far as 45 miles. All buildings and other obstructions are marked with fixed red lights and the boundaries of the aerodrome are outlined by red flashing lamps, so that a pilot has indicated beneath him the position of the buildings and the area within which it is safe to land and manoeuvre his machine.

There are various methods of indicating the direction of landing. At Croydon electric lights sunk into the ground under glass covers have been used to show a double "L" in any one of eight directions according to the wind; the same system is applied at

SPECIMEN ROLLING STOCK REQUIRED AT THE AERODROME

Continental aerodromes to show an isosceles triangle or the letter T. An automatic illuminated T, swinging with the wind, is in use at Littlestone and Penshurst. The illuminated "wind sleeve" has the merit of simplicity.

When landing it is important that the pilot should be able to see the surface of the ground distinctly. A floodlight of 4 million candle power has been developed which throws a flat fan-shaped beam horizontally over a large portion of the surface of the aerodrome, producing an effect equivalent to 75% daylight, with no confusing shadows.

BY COURTESY OF GENERAL ELECTRIC COMPANY AND WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY

METHOD OF LIGHTING AN AERODROME

Lighting for aviation had its inception during the World War. Reconnaissance and bombing expeditions by aircraft over enemy territory were frequently conducted after nightfall and the problem of lighting the aerodrome for take-off or landing was a new one. Portable arc search-lights and parachute flares came into use for night-flying activities. The year following the close of the war witnessed the inauguration of all commercial aviation and the work of developing lighting equipment for night flying began. In the conjectural representation above, all buildings and obstructions are marked with fixed red lights and the boundaries are outlined with fixed white lights. The floodlights throw a flat fan-shaped beam on the surface of the aerodrome enabling the pilot to see the ground distinctly. The beacons guide the aerial navigator toward the aerodrome.

International Obligations.—Under the International Convention for the Regulation of Air Navigation (*see* AVIATION, CIVIL) the contracting States, of which Great Britain is one, must nominate customs aerodromes, and the chief countries of the world have accepted it as a principle that the Government or local authorities should be responsible for providing and maintaining the air ports required in international air navigation. Every aircraft engaged in international flying must, before proceeding from one country to another, be cleared by the customs and must make its final departure from an appointed customs aerodrome; similarly an aircraft arriving from another country must make its first landing at a customs aerodrome for examination before proceeding elsewhere.

The Convention secures uniformity in such matters as markings, lighting, signals, rules, etc., at all public aerodromes belonging to the contracting States, whether owned by the Government or otherwise; also it provides that every public aerodrome must be available to the aircraft of all contracting States on exactly the same terms as to national aircraft.

The majority of contracting states have issued their own regulations. In the British regulations, which are laid down in the Air Navigation (Consolidation) Order, 1923, and Amending Orders, 1925 and 1927, an aerodrome is defined as follows:—

“Aerodrome” means any definite and limited ground or water area intended to be used either wholly or in part for the landing or departure of aircraft. Aircraft in this connection includes all balloons, whether fixed or free, kites, airships and flying machines.

All aerodromes in Great Britain and Northern Ireland, which are used as regular places of landing or departure by aircraft carrying passengers for hire or reward, must be licensed for the purpose by the Secretary of State for Air.

Service (Royal Air Force) Aerodromes.—Apart from the special facilities required at a civil aerodrome for commercial traffic, all the remaining features except as regards lighting are to be found equally at a service aerodrome—with the addition of quarters for the officers and airmen and the installations necessary for service operations and training.

The situation of a service aerodrome in peace time is governed largely by the nature of the units to be stationed there. It is gen-

erally unnecessary and undesirable that a service aerodrome should be located near a large town. The only exceptions to this rule are aerodromes belonging to squadrons of the Auxiliary Air Force which must be reasonably near the homes of their volunteer personnel.

Aerodromes used for training in flying are situated as a rule in the midst of open country to neutralize risk of forced landings. Aerodromes for fighting and bombing squadrons are disposed according to strategic requirements. As bombing squadrons are equipped with heavy aircraft it is particularly necessary in their case that the aerodrome should have a hard surface and not become soft in rainy weather. For co-operation with the Army and Navy it is necessary that aerodrome and seaplane stations should be provided in the vicinity of the areas employed for combined

training. A number of aerodromes are also required for experiment and tests in connection with new types of aircraft and equipment.

All British service aerodromes are available for use by civil

aircraft in emergency and may be used for setting down or taking up passengers where no other landing place exists.

(I. A. E. E.)

UNITED STATES

Airports are defined by the U.S. National Advisory committee for Aeronautics (Report 240, Nomenclature for Aeronautics), as "a locality, either of water or land, which is adapted for landing and taking off of aircraft; or a place used regularly for receiving or discharging passengers or cargo by air." On Feb. 25, 1928 there were 4,000 landing fields in the United States, of which 66 were airports equipped with rotating beacons and partially or fully equipped with flood, boundary and danger lights, etc.

Basic Requirements of the U.S. Department of Commerce for all certificated airports and fields are: (1) Field or landing area; firm and approximately level with suitable approaches, well drained and without obstructions or depressions hazardous to taking off or landing; or at least two landing strips roofed, or more wide crossing or converging at not less than 45° angles. These must permit safe landing in ordinary weather. If the sod or turf is not tough and hard enough for these purposes, the landing strips must be of cinders, slag, gravel, asphalt or other suitable material; then they are called runways. (2) There must be a margin of at least 100ft. clearance between the landing strip edges and field boundaries. Surrounding obstructions are calculated to diminish the margins by seven times the height of such obstructions. Thus, an "L"-shaped field having landing strips 100ft. wide and margins of 100ft. on both sides is sufficiently large if there are no surrounding obstructions. Should there be obstructions 50ft. high the margins between the obstructions and the edge of the landing strip must not be less than 350 feet. (3) The airport must be very near a good highway to the nearest city or town. (4) The airport must have an improved type of wind direction indicator and be marked by day with a landing circle 100ft. in diameter having a band 4ft. wide, the circle to be placed flush in the centre of the landing area or in the centre of the landing strip intersection. The name of the city or field must be in or near the centre of the marking circle. (5) The airport must be able to supply aircraft with fuel, oil and water, and the airmen with dependable communication and transportation facilities to the nearest city or town.

Geographical Location.—The aerodrome should be as accessible as possible to the population which is to be served. If it has to be at a distance from the community, it may be well to have smaller landing fields near the business centres. Congested residential areas where noise is objectionable should be avoided.

Size.—The weight of commercial aeroplanes necessitates generously long runways and wide safety zones through which to glide when approaching and to gain altitude when departing. The elevation above sea-level is important in determining the size of an airport as the length of runways required for taking off and landing increases with altitude. Thus an aeroplane requiring 1,500ft. for a normal take-off at sea-level would require about 2,300ft. at Denver, Colo., which is 5,280ft. above sea-level. An airport may be practically any shape which provides an unobstructed take-off and landing area of 2,500ft. which is considered adequate for the largest aeroplanes. It should be planned so that it may be changed in the future.

The U.S. Department of Commerce Ratings on Size of Fields.—In order to receive a rating on size from the U.S. Department of Commerce an airport must meet with certain basic conditions.

"A" Rating.—The field receiving an "A" rating must have 2,500ft. of landing area in all directions with clear approaches, the field to be in good condition for landing at all times; or it must have approved-type landing strips permitting landing in at least eight directions, the landing strips not to cross or converge at less than 45° angles, with appropriate margins and clear approaches. The margin between any obstacle and the landing strip must be a distance at least seven times that of the obstacle's height.

The airport may be of irregular shape, but must contain enough area to permit laying out landing strips to fulfil these requirements. A square field offers the most natural solution.

"B" Rating.—A square landing area 2,500ft. on a side, laid out in landing strips permitting at least four-way landing and having clear approaches. The landing strips must be at least 100ft. wide and clear at the sides and ends. Margins between obstructions and landing strips must extend a distance of at least seven times the height of the obstacle. Landing strips shall not converge or cross at less than 45° angles, preferably intersecting at 90° angles in the case of four-way landing.

"C" Rating.—The field must have 1,500ft. of landing area in all directions with clear approaches and in good condition for landing at all times, or a square landing area 2,000ft. on a side, laid out in landing strips permitting at least four-way landing and having clear approaches. Landing strip, margin, obstacle and angle regulations are as above.

"D" Rating.—The field must have 1,200ft. of landing area in all directions with clear approaches and in good condition for landing at all times; or, a square landing area of 1,500ft. on a side laid out in landing strips permitting at least four-way landing and having clear approaches. The other regulations are as above.

"E" Rating.—The field must have a square landing area of 1,200ft. laid out in landing strips permitting at least four-way landing and having clear approaches. The other regulations are as above.

"F" Rating.—Fields not having the minimum dimensions of an "E" rating for size, but from which flying operations are nevertheless taking place, receive the rating of "F" if request for rating is made.

"X" Rating.—All fields not considered safe for the operation of aircraft, but which are used, or have been used for such operations, and on which rating is requested are rated "X."

U.S. Department of Commerce.—Under the Air Commerce Act of 1926, the President entrusts an assistant secretary of commerce for Aeronautics with the aeronautics branch of the department of commerce. In addition to its other duties the aeronautics branch co-operates with State and local authorities in establishing airports in all large cities. This act provides that airports shall not be owned or operated by the Federal Government, and that no exclusive rights shall be granted for the use of civil airways, airports or other navigation aids owned by the United States. The Department of Commerce may rate airports as navigation aids.

The program of the Department of Commerce provides for lighting over 6,000m. of airways. The lights are placed about 30m. apart between airports on intermediate landing fields. The fields are leased by the Government and are not to be used for any purpose inconsistent with the landing and taking off of aeroplanes. A standard beacon is placed at every such intermediate field.

Cost and Revenue.—Data secured from 68 landing fields of various sizes located along contract air mail routes show an investment by cities of over \$17,000,000.

The following analysis of the cost of the Buffalo airport is typical of the expenditures in airport construction: Land (518ac.) \$411,000.00; building (3 hangars, 1 garage, 1 administration building), \$95,778.08; runways (2 cinder runways 3,000ft. long and 100ft. wide), \$48,528.56; grading and processing, \$47,875.32; new roads, \$9,148.18; drainage, \$33,549.00; paving, \$27,453.17; underground piping and electrical equipment, \$17,567.20; rolling stock and parts (1 service truck, 1 five ton carryall, 1 light delivery truck, 1 coupé, 1 grader, 1 tractor), \$14,123.81; office equipment and supplies, \$2,563.05; insurance, \$6,039.05; store-room supplies, \$709.21; telephone and light during construction, \$671.23; machinery and tools, \$9,580.58; miscellaneous labour and supplies, \$2,568.72. Income may be derived from rent from hangars, rent from postal, express and passenger accommodations, rent from restaurants, various concessions, landing charges, night lighting charges, sale of gasoline and oil, etc.

Buildings and Equipment.—The department of commerce recommends that all buildings be situated at a point not nearer the landing area than seven times the height of the tallest building. To receive the rating "A" an airport must have one or more hangars at least 80ft. by 100ft. with a clearance of 18 feet. Where the ground is soft or muddy these should be connected with the runways by specially prepared roadways of cinders, concrete or other suitable material.

Drainage and Soil.—Artificial drainage may be supplied by blind ditches filled with coarse gravel topped with cinders, and tamped down flush with the surface of the field. If the precipitation is heavy it is often necessary to lay tile pipe, with open joints, in the bottom of the ditches.

Landing fields surfaced with sand or cinders are seldom satisfactory in dry weather as stones, sand or dust may be caught up by the air driven astern by the airplane propeller and prove annoying to passengers, damage wing surfaces and cause motor trouble. If the existing surface of the airport is not durable enough for continuous use it may be made so by sowing tough, deep-rooted grass which will not readily develop ruts, mud holes and tail skid scars.

Lighting.—The lighting facilities believed essential for the safe night operation of an airport are:

(1) A rotating beacon of several million candlepower, tilted slightly upward and mounted on a tower in order to clear obstructions so that it may be visible in all directions.

(2) White boundary lights showing the shape and size of the airport.

(3) Green approach lights to show the most favourable avenues of approach.

(4) Lights illuminating the wind cone, which indicates the prevailing direction of the wind, against which the aviator has to land.

(5) Red obstruction lights to mark all buildings, pole lines, radio towers, and other dangerous obstructions within gliding or take-off distance of the landing field.

(6) Flood lights to give pilots the proper perspective and to indicate to them that portion of the field which should be used for landing.

(7) Ceiling lights which are used to enable the airport officials to determine the height of the clouds above the ground. This information is obtained by projecting a beam of light toward the clouds at an angle of 45°, and then measuring the distance from the light source to the point directly beneath the spot it makes upon the clouds, which gives the height of the clouds above the ground; that is, the height of the ceiling. Information of this sort is transmitted to other airports so that aviators may be advised of the visibility at various points.

Identification Markings.—The centre of the landing field at each airport should be marked with a circular band 4ft. wide and 100ft. in diameter. It is prescribed that the name of the airport be near the circle, composed of letters whose minimum height is 15 feet. This marker may be constructed by removing the earth, where the letters are to be placed, to a depth of 6in., and filling in with smooth stones to the field level; whitewashing the stones makes the marker visible from a height of several thousand feet. The roofs of factories and other buildings near the airport should be so marked as to aid pilots in finding the landing field with as little search as possible. Where the entire field is not available for landing, the runways should be indicated by arms projecting from the circle described above.

Roofs of hangars or other structures at the airport should be marked with the name of the field. Arrows indicating the name and direction of other airports and cities, and also an arrow with a letter "N" superimposed pointing to true north should be displayed on the airport buildings. (J. C. McG.)

General information on the construction and equipment of airports has been prepared by the department as "Information Bulletin No. 2, Construction" and "Information Bulletin No. 36, Rating of Airports."

AERODYNAMICS. The word aerodynamics is applied both to the study of the disturbances generated in air by the passage of solid bodies, such as aircraft, and to the study of the mo-

tion of free aircraft under the influence of air reactions. The former is a specialized development of *fluid dynamics* and the latter of *rigid dynamics*, i.e., the dynamics of rigid bodies under the action of external forces. (See DYNAMICS and HYDRODYNAMICS.)

The equations of motion of a slightly viscous fluid such as air can be formulated, but have not in general been solved, and in no instance has the complete motion of the air passing a body, such as a wing, been calculated directly from the laws of motion. Aeronautics is thus dependent for its data mainly upon direct experiment, and since quantitative experiments upon the full scale are difficult and costly, the bulk of the data available has been obtained upon small models of the parts concerned suspended in artificially induced currents of air. The technique of the measurement of air reactions upon models suspended in "wind tunnels," (see AERONAUTICS) as the tunnels containing these air currents are called, has reached a high development and many tunnels of great size and power have been built in all countries seriously concerned with aeronautics. The largest wind tunnel in England is in the National Physical laboratory at Teddington near London; it has a cross section of 7ft. by 14ft. and is operated by two fans, 11½ft. diameter, driven by two electric motors of 200h.p. each. This tunnel can take a model one-fifth as large as a modern two-seater aeroplane, and this model is sufficiently large to carry an air-screw driven by an electric motor within it.

It is clearly of importance to determine how nearly similar is the manner in which the air flows around such models to the manner in which it flows around the corresponding full scale aeroplane. In many aeronautical problems air can be treated as though it were an incompressible and inviscid fluid. In these cases it can be shown that *similar bodies moving in a similar manner will generate similar air flows*, no matter what the size of the body, the density of the fluid, or the speed of the motion. Even the nature of the fluid, whether liquid or gas, is of no consequence, and experiments intended to relate to air may equally well be carried out in water, or in any other fluid which, for the purpose in hand, can be treated as incompressible and inviscid. The simple laws of aeronautics, such as that the pressure varies in proportion to the density of the air and to the square of the speed, are based upon this assumption.

Effects of Compressibility and Viscosity.—In aeronautics air can generally be treated as though it were incompressible, unless velocities exceeding some 300 or 400 miles per hour are involved. When velocities higher than this occur, compressions and expansions of the air as it passes the solid body may seriously influence the flow; the rule for similarity of flow becomes less simple. It is then necessary that corresponding velocities in the motions to be compared should all bear the same ratio to the velocity of sound in the fluid in which the motion takes place. For example, if high speed experiments in air and water are to be strictly comparable, the experiments in water must be carried out at speeds four times as great as the corresponding speeds in air, because sound travels some four times as fast in water as in air; but when both the model and the full scale body move through air the actual speed of the model must be the same as that of the full scale body. Such high speeds as 300 to 400 miles per hour are not yet commonly met in aeronautics, except at the tips of the blades of high speed airscrews, and hence it is unnecessary to obey this law of similarity, except in connection with the tests of such screws.

For fluid flows which are appreciably influenced by viscosity yet another condition must be fulfilled to ensure similarity between two motions. Let μ be the viscosity of the fluid, ρ its density, V the velocity of the body through the fluid, and let l be some length which defines the size of the body—for instance the diameter, if the body be a sphere, or the length, if it be an airship. Then the quantity $\frac{\rho V l}{\mu}$ must have the same value in each of the motions to be compared, otherwise viscosity will play a different part in each motion, and strict similarity will be impossible. This quantity $\frac{\rho V l}{\mu}$ has zero dimensions and is therefore a pure number or ratio,

independent of the units in which its separate factors are expressed, provided that those units form a dynamically consistent system, *i.e.*, a system of units which allows Newton's laws of motion to be expressed in the form:—Force = mass \times acceleration, the pound-poundal-foot-second and the gram-dyne-centimetre-second systems being examples. It is universally known as the *Reynolds number*, after the celebrated scientist Osborne Reynolds. When the Reynolds number of a flow is small, viscosity

FROM HAYLER AND FRAZER, "REPORTS AND MEMORANDA OF THE ADVISORY COMMITTEE FOR AERONAUTICS" BY PERMISSION OF THE CONTROLLER OF H.M. STATIONERY OFFICE

FIG. 1.—THE TURBULENT FLOW OF FLUID PAST A CYLINDER

This illustrates the flow round all bodies which offer a high resistance to rapid motion through fluids. The motion of the fluid, which is from left to right, is characterized by a dead region A, followed by a turbulent wake B. Such a flow exerts a powerful drag upon the body

will play a predominating part in the motion, which will be of the kind usually associated with the flow of oils or treacle. When the number is large, the flow will be of the kind usually associated with water, and will approximate to that of an inviscid fluid. Thus the same fluid may act in a highly viscous manner when flowing slowly past small objects, and yet behave almost as though inviscid when flowing rapidly past large bodies. The Reynolds numbers which are of interest in aeronautics are of the order of a million; in these circumstances the air behaves almost as though it were inviscid, and the simple laws of comparison between model and full scale, to which reference has been made, can generally be applied without serious error. Certain flows, which are of great interest in aeronautics (*e.g.*, the flow about a wing at the stalling angle which is defined later) are, however, highly critical, in the sense that small disturbances may cause an entire change in the type of flow. These critical flows may be sensitive to changes in the Reynolds number, even though the value of the number is very large, and hence the greatest caution must be used in applying the results of small model experiments on these critical phenomena. The highly practical importance of some of these critical flows has led to great efforts being made to devise laboratory experiments in which the Reynolds number will be the same as that of the full scale flow to be represented. One way in which this has been successfully accomplished, though at great cost, is to enclose the whole wind tunnel in an air-tight chamber pumped up to a pressure of some 20 atmospheres; this increases ρ some 20 times, which compensates for the reduction in V and l necessary to bring the experiment within the scope of laboratory methods.

FLUID MOTION

The forms taken by the flow of air past a solid body can in general be classified as belonging to one of two characteristic types. Fig. 1 is typical of the flow around the majority of bodies not specially shaped to move easily through fluids. The motion, which in this figure is from left to right, is characterized by a dead region *a*, of small velocity and low pressure, followed by a turbulent wake *b*. Such a flow exerts a powerful drag upon the body, and much energy will be required to force the body rapidly through the fluid. Fig. 2 is typical of the flow around bodies which move easily through fluids, the dead region *a* is absent, whilst the wake has become very small. Flows of this type are generally called *streamline* flows, and bodies which generate them are called *streamline* bodies. The turbulent flow, as in fig. 1, is not yet susceptible to mathematical analysis, but streamline flows, as in fig. 2, approximate, when the Reynolds number is large, to

the flow of a hypothetical inviscid fluid, the analysis of which has been thoroughly studied.

Bernoulli's Theorem.—This famous theorem relates to the steady flow of the hypothetical inviscid fluid, and states that the pressure p and the velocity v at all points on a single streamline are connected by the relation:

$$p + \frac{1}{2}\rho v^2 = \text{constant.}$$

In most aeronautical problems the air at all points far from the body is assumed to be undisturbed, so that its velocity relative to the body and its pressure are uniform; if these are called V and P respectively, then Bernoulli's equation leads easily to:

$$p - P = \frac{1}{2}\rho V^2 \left[1 - \left(\frac{v}{V} \right)^2 \right]$$

from which the pressure at any point can be deduced from the velocity at that point, or vice versa. The maximum pressure will thus occur where v is zero, and will have the value of $P + \frac{1}{2}\rho V^2$; this maximum pressure occurs on the surface of the solid body at the point where the streamlines divide. (See figs. 1 and 2.) This fact is used to measure the velocity of air in aeronautical experiments. If a tube, closed at one end and open at the other, is placed with the open end facing the air stream, the pressure within it will have the maximum value $P + \frac{1}{2}\rho V^2$. If the difference between this pressure and the pressure P of the undisturbed stream can be measured and if the density is known, the velocity V can be determined. The undisturbed, or static pressure P can be obtained within a closed tube placed with its axis parallel to the wind and having small holes punctured in its sides at some distance from the closed end. These two tubes are known respectively as the *pitot* and *static pressure* tubes; and together with some form of manometer, for measuring the difference between the pressures within them, they provide the standard speed measuring unit both in the laboratory and on aeroplanes in flight.

The Flow About a Streamline Body.—The theoretical study of a hypothetical inviscid fluid leads to the conclusion that when a solid body starts from rest to move through such a fluid, which is otherwise undisturbed, the form of the flow around the body is uniquely determined by its shape and mode of motion. This flow has the remarkable property that, although it may cause variations of pressure which tend to rotate the body, it exerts no resultant force upon the body, no matter what the shape of the body may be. The actual air flow about a streamline body, such as an airship (fig. 2) is a very close approximation to this theoretical flow, and hence the resultant of the pressures upon the surface of the body is almost zero—the small remaining drag, or resistance to motion, being nearly all due to *skin friction*, *i.e.*, the tangential forces on the surface due to the friction of the air. When the Reynolds number is large, as in aeronautics, the fluid

FIG. 2.—THE FLOW OF FLUID PAST A "STREAMLINE" BODY

In contrast to the turbulent flow round a body not especially shaped to move easily through fluids as in Fig. 1, this illustrates the flow round a body which offers small resistance to rapid motion through fluids

mechanism which exerts these skin friction forces is confined to a very thin sheath, or layer, enveloping the body. This is called the *boundary layer*; the motions within it are very complex and are known to provide the determining factor which decides whether the flow will be streamline or turbulent. Outside this very thin boundary layer the flow, if streamline, behaves very closely as though the fluid were absolutely inviscid.

A wing may be loosely described as a flattened streamline body. Its cross section in one plane containing the direction of motion

has a typical streamline form, as in fig. 3 (see also AEROPLANE) which shows a modern wing section. So long as the incidence, or inclination of this section to the direction of motion is not too great, the flow about the wing will be streamline, the drag will be small and the wing will exert a lift perpendicular to the direction of motion which increases progressively with the incidence. If the incidence becomes too large the flow changes, more or less suddenly, to a form similar to that in fig. 1. The wing is then said to *stall* and its resistance to motion is greatly increased, whilst its lift no longer increases with incidence, but may even fall slightly.

Below the *stalling angle* the flow, though streamline, differs from that unique flow which could be generated from rest in an inviscid fluid, and approximates more nearly to one of a series of flows, which are possible to the inviscid fluid, but which could not be generated in it without the action of some additional agency. The way in which these flows are generated is still somewhat obscure, but it is known that their development is made possible by the slight trace of viscosity in the air, which allows eddies to be

FIG. 3.—AN EXAMPLE OF A RECENT AEROPLANE WING SECTION
The most modern type of wing is more or less a flattened streamline body. The actual air flow about a body of this shape is such a close approximation to the theoretical flow that the pressure upon its surfaces is almost zero

shed from the trailing edge of the wing, and that as these eddies are shed the flow about the wing changes until the appropriate flow has developed. When these changes have ceased and the flow has become steady the viscosity plays no further appreciable part in the motion, except in the boundary layer. Theoretically there are, for each wing at each incidence, a series of such flows which could exist steadily in the inviscid fluid but could not be generated in it, and a question arises as to which one of them will occur in any given instance. Unlike the flows which could arise from rest in an inviscid fluid, these flows give theoretically, a lift upon the wing, and if the actual lift of the wing can be measured, the particular flow of this series which is occurring can be identified as that one which theoretically gives the measured lift. It is thus possible, by merely measuring the total lift of a wing, to calculate, with considerable accuracy, the direction and velocity of the flow at all points in its neighbourhood and from Bernoulli's equation the distribution of pressure over its surface. If the lift cannot be measured, the flow can be approximately identified as that one of the series in which the streams flow smoothly off the trailing edge of the wing without sharp changes of direction. This method of identification is not so accurate as the former.

Induced Drag.—Calculations such as the foregoing can most conveniently be made in relation to wings of infinite span, or length perpendicular to the direction of motion. For such wings the theoretical drag in the inviscid fluid is zero; the real drag is almost entirely due to skin friction and is so small that it may, in favourable circumstances, be less than one fiftieth of the lift. When the span of the wing is finite, circulations are set up around the tips, the air flowing round them from the high pressure region beneath to the low pressure region above the wing. Vortices are thus generated, which trail from the wing tips and remain in the air long after the wing has passed. These vortices require power for their generation and consequently the power required per running foot to propel a finite wing, and the drag on the wing, are greater than for a wing of infinite span: for this reason the drag of a wing of practicable shape is seldom less than one-twentieth of the lift. L. Prandtl has developed approximate mathematical methods of calculating this drag, which he calls the *induced drag*. The difference between the actual and the induced drag is called

the *profile drag*, because it depends upon the profile, or cross section, of the wing and is not dependent on the span.

For a given wing arrangement, the induced drag is proportional to the ratio, weight supported/span; this ratio is now called the *span loading*. The induced drag varies in *inverse* proportion to the air density and the square of the speed. The profile drag, for a given incidence and profile, depends upon the total wing area and varies in *direct* proportion to the density and the square of the speed. When calculating the drag of an aeroplane wing, it is now normal practice to divide the drag into these two parts and to study them separately. Induced drag can be calculated, not only for single wings, but for multiple wings, as in a bi-plane, or for wings in the presence of plane boundaries, such as the walls of a wind tunnel or the surface of the earth. Such calculations are used extensively in all modern laboratories and design offices.

FREE FLIGHT

Stability.—An aeroplane which, on being disturbed from a condition of steady flight in equilibrium, ultimately returns to the condition from which it was disturbed, is said to be *stable*. Complete stability in this sense can be achieved by correct proportioning of the parts of the aeroplane, but is by no means necessary for successful flight; for if the pilot has effective control over his aeroplane he can easily check any tendency to depart from equilibrium flight, which may result from a moderate instability. It is, however, important for the designer to know, not only whether his aeroplane will be stable or unstable, but the degree of stability or instability to be expected, for its behaviour in the hands of the pilot will depend upon this factor. The subject has therefore been extensively studied mathematically, but is so complicated that it is impossible here to do more than refer the reader to standard books on the subject.

Stalling.—As the speed of an aeroplane falls the lift falls, and sufficient lift to balance the weight can be obtained only by an increase of incidence. But it has been shown in a previous paragraph that when the incidence of a wing passes a certain critical angle the character of the air flow changes, and the lift ceases to increase. There is thus a minimum speed, associated with the above critical angle, at which any aeroplane can fly steadily. This minimum speed of steady flight is called the *stalling speed*, the incidence at which it occurs is called the *stalling incidence*, and an aeroplane flying at an incidence greater than the stalling incidence is said to be flying *stalled*. With this change of flow at the stalling incidence is associated a complete change in the characteristics which determine the stability of aeroplanes and the action of their controls. For the effect of this change upon practical aviation see AEROPLANE.

AERO ENGINES. Aero engines in use in the first quarter of the 20th century worked upon the four-stroke constant-volume-ignition cycle and the thermodynamic theory of them was similar in all essentials to that of any other petrol engine. (See INTERNAL COMBUSTION ENGINE.)

I. ELEMENTS OF THE PROBLEM

The great problem with which the designer of aero engines is faced is reduction of the ratio weight to horse-power, or as it is customarily expressed the "pounds per horse-power," to the smallest possible value consistent with reliability. But pounds per horse-power in the air cannot be taken simply as a figure obtained on the test-bed; an aeroplane must carry its own fuel, so that economy of fuel consumption is also of primary importance. If we take, in order to fix our ideas, the example of a 450-h.p. engine which itself weighs, say 900 lb., then the weight of fuel

used per hour would be of the order of 225lb., depending, of course, at what height the flight was made.

If we consider, not the weight of the engine alone, which is 2lb. per h.p., but the weight per h.p. of the "power unit (engine and fuel) for a four hours' flight," then the value of this when the aircraft leaves the ground will be not 2 but 4, and it becomes at once clear that the effective weight to power ratio of an engine in flight will be materially affected by its fuel economy. In 1915 there was no water-cooled engine which weighed, complete with water and radiator, less than about 4lb. per h.p., and no air-cooled engine of less than 3lb. per horse-power. Since that time these figures have been reduced to less than 2 and 1.5 respectively. The greater net weight of the water-cooled type is discounted, especially for long flights, by better fuel economy.

Tendency of Design.—For an engine of given size (bore and stroke) both the power and economy are increased by an increase of the compression ratio. The tendency of design has therefore been toward the use of higher and higher ratios of compression: from the figure 4.5 of the average motor-car the compression in aero engines has been pushed up to 6 to 1, and even much higher in special cases. The limit to which it can be raised depends largely on the physico-chemical properties of the fuel available. With some fuels, such as benzol, an engine of 7 to 1 compression ratio will run quite smoothly. With others which differ only in chemical analysis and not at all in appearance, volatility or specific gravity, it would be impossible to run the engine at all. Owing to the high degree of compression, the combustible gas when ignited would explode with such violence as to cause "detonation" or "knocking" in the cylinders. In order that the compression ratio may be pressed to the highest possible point, therefore, the supply of suitable fuels for aero engines is a matter of great importance.

The Factor of Head Resistance.—The aero engine designer must bear constantly in mind the factor of "head resistance." When an aeroplane is flying level, the whole available power of the engine is used up in overcoming the "drag" on body and wings as the machine tears forward through the air. In practically all modern machines the engines are at the front of the body or fixed between the wings, and if the head resistance is to be kept down, the area presented by the engine and accessories, when viewed from the front, must be as small as possible. A most important accessory, in this connection, is the radiator necessary with water-cooled engines.

II. EVOLUTION IN DESIGN

Bearing in mind the four considerations of power, weight, fuel economy and head resistance, their effect upon aero-engine design will now be traced. The designer must be a master of compromise. Compactness, rigidity, revolutions, inertia forces, piston speed and area, bearing loads, valve area, effective cooling and the rest . . . each member of this complex company must be harmonized with all the others and at the same time consideration of each must be pressed to the farthest limit in the service of the two great aims of power and lightness.

Two Main Types.—It is appropriate in the first place to point out the main subdivision into water-cooled and air-cooled types. With our primary concern for weight to power ratio the advantages of the air-cooled type are not far to seek; there is the clear gain in weight of all the circulating water, besides the elimination of the weight and drag of the radiator. But the air-cooled engine designer cannot have it all his own way. For minimum head resistance of the engine itself a design of the "cylinders-in-line" type with the crank-shaft fore-and-aft will clearly have the advantage; but if for cooling we rely wholly upon a high velocity air-stream it is imperative that no cylinder should be seriously more screened from this air-stream than any other.

Hence, although a few air-cooled engines of the cylinders-in-line type have been built, the two types which have been widely successful have been those in which the cylinders are arranged radially in one plane (see Pl. II.-1), or sometimes in two parallel planes (see Pl. II.-2), perpendicular to the axis of the machine; so that all cylinders share equally in the cooling air. Such engines,

whether of the "rotary" or "static radial" types, present a large frontal area and offer very serious head resistance, in fact, far in excess of the radiator. The difficulty of air cooling is that the specific heat as compared with water is only 1/45, lb. for lb., or 1/36,000, volume for volume.

Water-cooled Engines.—The power developed by an engine depends upon the mean piston speed, the total piston area and the mean-effective pressure in the cylinders. As to the first two the question at once arises: "Shall the requisite piston speed and area be achieved with a few large or many small cylinders, and what in each case are the limiting factors in regard to speed?"

Cylinder Design.—The answer given by designers has been "many and small"; largely on account of the resulting compactness and of the rigidity obtainable with light construction. A long stroke means a heavy crank-shaft and a cylinder reaching out a long way from the shaft centre-line and upsetting the slip stream from the propeller. For getting adequate piston speed, therefore, the tendency is toward a short stroke and high revolutions. Large-bore cylinders in line, again, would lead to a long crank-shaft, involving both weight in itself and in the resulting crank-case, besides the danger of non-rigidity in a big engine of light crank-case construction. A further advantage of small cylinders is the reduced danger of distortion due to uneven heating while in service.

With many small cylinders in line we get less piston area to the same length of crank-shaft, but it is possible to make two or more cylinders operate on one crank and so the balance is redressed. Considerations of this kind have led to the development of the "Vee" and "Broad-arrow" types of engine with two and three banks of cylinders. Fig. 2 on Plate I. shows one of the most successful modern water-cooled engines of the Vee type, the Curtiss D.12 which develops 400 b.h.p. at a total weight of 724lb. This engine has a crank-throw of only 3in. and the compactness of the resulting design is evident.

In Pl. I.-4 is the well known Napier Lion with three banks of four cylinders each. This engine has a crank-throw of only 2 $\frac{1}{8}$ in., but works at enormous speeds, in the neighbourhood of 3,000 r.p.m.; for a short stroke means high revolutions to get adequate piston speed, and this in turn involves big inertia forces (since they increase as the square of the revolutions) which become most serious in their effect on the bearing loads at the crank-pins. The limit to the closeness of spacing of the cylinder centre lines, with these high-speed engines, is largely a matter of the provision of adequate lengths for the main bearings and for those between connecting-rods and crank-pins.

Valve Problems.—The combination of high piston speed with good volumetric efficiency involves ample valve area and the freest possible form of induction system. This, combined with the need for a compact and symmetrical combustion chamber to diminish detonation, has resulted in the almost universal adoption of four valves in the cylinder head, two inlet and two exhaust, the inlet being rather larger than the exhaust. By this arrangement an effective inlet valve area is obtained equal to about 20% of the piston area. With this provision mean piston speeds up to well above 2,000ft. per minute can be employed with good volumetric efficiency.

Next to the big-end bearing loads, valve operation is most critically affected by high revolutions. To get sufficiently rapid opening and closing of a poppet valve for an engine speed of 2,500 r.p.m. the accelerations involve very heavy springs and terribly severe stresses in the cams and in the valve spindles. This difficulty of high-speed poppet valve operation makes the sleeve valve so attractive a possibility.

Fuel Distribution.—With a number of cylinders in line the equal distribution of the fuel between them is a difficulty. Two or more carburettors must be used and the cylinders drawing from each carburetter must be arranged, so far as possible, to do so at equal time intervals. No one arrangement has been standardized as the best: on most 12-cyl. Vee engines one carburetter serves one whole bank of cylinders, but another arrangement divides the engine into two groups of the front six and rear six cylinders, and each group is served by one carburetter.

In at least one design some weight is sacrificed for the sake of good distribution in the provision of a carburettor to every two cylinders.

Air-cooled Engines.—Air cooling, while using an extremely inferior cooling medium, is found possible by the discovery that engines will operate at very high cylinder and valve stem temperatures. The two main classes of air-cooled engines are the Rotary and the Static Radial types. In each the cylinders are arranged radially in one or two planes round the circumference of a circular crank-case. Thus all cylinders are satisfactorily exposed to the cooling air-stream, but at the cost of presenting a large frontal area. The rotary engine, in which the cylinders and crank-case rotate with the air-screw, besides the fore and aft air-stream, gets the extra cooling due to the rotational speed of the cylinders, but at the expense of considerable waste of power in air friction.

The speed, and therefore the power, of the rotary engine is limited to about 1,200 r.p.m. by the enormous centrifugal forces on the rotating cylinders, and in consequence this type has now become obsolete.

One of the chief attractions of the static radial type is the possibility of a very compact and rigid crankcase construction (*see* Pl. I.-4). This takes the form, very roughly, of a drum, with cylinders fixed radially round its circumference. Only one crank is employed for all the cylinders which lie in one plane; one piston having a connecting rod with a "big-end" as ordinarily understood, while all the other pistons have "articulated" connecting rods, which are attached by pin joints around the circumference of the big-end of the one master-rod, as shown in Pl. III.-3, where the master-rod points vertically upwards. The loading on the one crank-pin is very severe, and special designs of big-end bearing are necessary to stand up to it.

Valve Design.—Valve opening is accomplished by push-rods and rocker-arms which are carried on the cylinder heads; the rods being operated from a cam-ring which is driven at the speed appropriate to the number of cylinders by an epicyclic gear on the main shaft. Since the cylinders of a large, air-cooled, radial engine may undergo an expansion while running of as much as 70/100ths of an inch, which is not shared by the push-rods, very careful design and proportioning of the rocker-arms are necessary if valve operation is not to be upset.

Fig. 3 on Plate I. is an illustration of the Jupiter engine, one of the most successful of the air-cooled radials. Its nine cylinders, $5\frac{1}{2} \times 7\frac{1}{2}$ in. bore and stroke, are arranged in one plane and the engine develops 450 h.p. at its normal speed of 1,700 r.p.m. and at a weight complete of 730 lb. Pl. II.-2 shows the Jaguar engine in which 14 cylinders are arranged in two planes.

Other forms of air-cooled engines which have met with the greatest favour outside of England are the Gnome, made by the Société des Moteurs Gnome & Rhone, which is the pioneer of all air-cooled engines; and in America the Wright "Whirlwind," Pl. III.-2, and Pratt & Whitney "Wasp," Pl. II.-6, engines are noted examples.

III. MATERIALS

With the cutting down of weight, and the ever more severe conditions as regards temperature and compression ratio, the problem of design is bound up with that of materials.

Aluminium Alloys.—The introduction of the light alloys of aluminium was the first great advance in regard to materials. It is now possible to make extremely complex castings and drop forgings for a complete crank-case in this material (*see* Pl. I.-4), and, even before this had been successfully achieved, the introduction of the aluminium piston had largely reduced the mass of reciprocating parts and so brought relief in crank-pin bearing loads due to inertia. The high conductivity, too, of aluminium as compared with cast-iron has made for cooler pistons and less tendency to carbonization of the lubricating oil. The same property has led to extensive use of aluminium for making the cylinder heads of air-cooled engines, and, in combination with a steel liner, for complete cylinder construction of water-cooled types. It has even been tried to run a steel or iron piston direct

in an aluminium cylinder. The two critical points in regard to high temperatures in a high-duty engine are the centre of the piston, and the exhaust valve, if this is of the poppet type.

Alloys of magnesium with copper and zinc or aluminium are lighter than the aluminium alloys. They cast well and machine easily and have been used to some extent for crank-cases with a saving of weight of about 35%. Their disadvantages are their high cost, excessive liability to corrosion and poor elastic properties.

Exhaust Valve Materials.—Exhaust valves are called upon to run continuously at a bright red heat and to resist scaling or burning under these severe conditions. The only steels which can successfully do this are certain of the nickel and chromium alloys, and these in their turn introduce new problems: they are much more troublesome to machine than carbon steels and also they develop what is known as "temper-brittleness," a condition brought about by the high temperatures at which they are used, and their subsequent slow cooling after use.

IV. THE SPECIAL PROBLEM: ALTITUDE

Effect on Engine and Air-screw (Air-screw termed propeller in the U.S.).—Under comparable conditions the pressure developed in the cylinder of an internal combustion engine will be proportional to the weight, and therefore to the density, of the combustible mixture drawn in. At heights above ground level the atmospheric pressure falls off at a rate of roughly 1 in. of mercury per 1,000 feet. At the same time the average temperature of the air becomes lower at a rate and in a manner which varies from day to day. The density of the air will therefore fall off somewhat less rapidly with height than the pressure, and the relation between density and height may be very variable.

It is now possible to measure the indicated power of an engine in flight, and experiments on these lines have shown that the indicated power is very nearly proportional to atmospheric density, provided a proper air-fuel ratio is maintained. This, however, is a matter of some difficulty. The suction produced in the choke tube of a carburettor—and hence the quantity of fuel normally supplied through the jets—will, for the same engine speed, be proportional to the square root of the air density. The weight of fuel supplied by a carburettor will therefore fall off less rapidly, as an aircraft rises, than the weight of air drawn in, and the mixture will become too rich. To compensate for this an "altitude control" must be fitted which reduces the normal flow of petrol at high altitudes.

Engine and Air-screw.—The useful performance of an aircraft engine cannot be considered apart from its air-screw. These two must be regarded together as the power unit, for the power and efficiency of an engine may be largely thrown away if combined with an inefficient air-screw. Since both indicated engine power and air-screw resistance are proportional to air density, at constant speed, it follows that they both fall off at the same rate as the aircraft climbs. The b.h.p. of the engine, friction losses being approximately constant, will fall slightly more rapidly; but the difference is not large, except at great heights, and since air-screw resistance is also proportional to the square of the revolutions the difference between available engine torque and air-screw resistance will produce only a slight drop in the speed of rotation. A fixed bladed air-screw, therefore, combined with a normal engine will, as the machine climbs, continue to work at nearly constant revolutions and efficiency.

Variation of b.h.p. with Altitude.—Although the indicated power falls off, the mechanical losses in the engine as a whole will not vary much as a machine rises, so that b.h.p. may be expected to fall off more rapidly than indicated horse-power and air density. To determine by direct observation just how fast the b.h.p. falls off with increasing altitude in any given case would be a research of the highest interest. Its accurate determination would involve measurement of the torque actually delivered to the air-screw. Several attempts have been made to design a torque meter for use in the air, but the mechanical difficulties are so great that so far these attempts at direct measurement have been only partially successful.

The alternative is to deduce how the b.h.p. varies from observations of the performance of the aircraft. This again is a difficult calculation to make with certainty from figures for speed and rate of climb, since the necessary reduction from actual observations must rest upon an answer to the question we are asking: how the altitude has affected engine b.h.p. and air-screw efficiency. It is probably impossible, by tests in the air, to arrive at any satisfactory general law for diminution of engine b.h.p. with height, applicable to all engines, for the simple reason that the mechanical efficiency, which must always vary from engine to engine, and may even vary from day to day with the same engine, has so large an effect on an aircraft's performance as to produce very discordant results. Take, for example, an engine giving 500 i.h.p. on the ground, and assume that the i.h.p. will fall off in proportion to air density and the friction losses remain nearly constant. If we calculate the b.h.p. at 20,000ft. where the i.h.p. is halved, this will be 200 or 175, a difference of $12\frac{1}{2}\%$, according to whether the mechanical efficiency is 90% or 85% on the ground. Even 1% variation of mechanical efficiency would have an appreciable effect on performance.

Examination of the results of a large number of aircraft performance tests has led to the conclusion that the best approximation to a law of variation of b.h.p. with height is to take this as being a function of $(\text{pressure})^{\frac{2}{3}} \times (\text{density})^{\frac{1}{3}}$. For a full consideration of this problem reference should be made to the Reports and Memoranda series of the Aeronautic Research Committee. Low pressure refrigerating engine test chambers at the Bureau of Standards in Washington have gone far to determine these unknown factors.

Maintenance of Ground Power at Altitude.—Since the power delivered by an engine will be roughly halved at a height of 20,000ft., any plan for counteracting this effect of reduced air pressure holds out great opportunities for improved performance. But here the air-screw problem comes in. If the ground power of the engine should be delivered with the air-screw in low density air, then the engine will race away and burst, for unless the inclination of the air-screw blades can be altered the resistance to rotation must fall off with the air density. The usefulness of maintaining ground power at altitude is therefore dependent upon adapting the pitch of the air-screw blades so as to prevent excessive engine speed and at the same time retain a good air-screw efficiency. This problem of providing a variable pitch air-screw is one which is at present occupying our designers, and cannot be said yet to have been satisfactorily solved but it has been overcome by a compromise with what may be known as "over-loaded screw" at low altitude.

Supercharging for Maintaining Ground Power.—To maintain ground power, combustible mixture must be compressed so as to be delivered to the cylinders always at normal atmospheric density whatever the height. This would mean, at 25,000ft., compressing in the ratio of 2.7 to 1 and then cooling through about 60° C. The necessary cooler involves additional head resistance and, if a piston compressor is used, the displacement will have to be about three times that of the main engine. All this means considerable additional weight, and every added pound is a dead loss at low altitudes and a serious handicap in getting off the ground. For this reason very high-speed rotary blowers offer the best chance of success. Such a blower might either be gear-driven from the engine shaft, or some of the energy of the exhaust gases might be used through the medium of an exhaust-gas turbine. The difficulty attending a blower, if gear-driven from the main shaft, is that, with the exceedingly high gear ratio necessary, about 10 to 1, the inertia of the blower rotor is enormous, and unless some slipping clutch device is provided the gears will probably be stripped on the very sudden starting-up of the engine.

The exhaust turbine drive is very attractive, for, whereas with a gear-driven blower the entire horse-power needed for compressing the air has to be supplied by the main engine, this type makes use of what would otherwise be largely wasted energy. The difficulties are chiefly those of providing turbine rotor blades which will stand the constant exposure to the hot exhaust gases

and at these temperatures will retain a strength adequate for a speed of rotation of 25,000–30,000 revolutions per minute.

V. OTHER PROBLEMS

Fuel Economy.—As mentioned earlier, the economical use of all fuel carried in the air is of vital importance. This means the uniform distribution to all cylinders of the minimum fuel required under all conditions of operation. This uniform distribution is a problem of induction manifold design very difficult to solve. A workable method of metering out to each cylinder its proper quantity without adding excessive weight to the engine would constitute one of the most important advances which at present remain to be achieved.

Wireless Interference.—While the engine designer has been improving the power and efficiency of his magneto and ignition system to suit high-compression engines, great strides have been made by the wireless branch in short wave-length instruments. The magneto and high-tension leads produce waves which upset the sensitive wireless sets, and methods must be devised of so screening off the effects of the ignition system as to allow advantage to be taken of the improvements in signalling apparatus. The high-tension leads are therefore enclosed throughout their whole length in a woven metal sheath which is "grounded" to the engine body, and at the same time the plug-heads and contact-breaker are enclosed in small metal cowls which are likewise grounded. But the hard-won improvement in ignition efficiency is cut down by the added electrical capacity introduced by the new screening arrangements, the effect of which, and the additional weight involved, are a dead loss to the engine designer.

Oil Temperature Control.—The functioning of a system of forced lubrication, in which oil is delivered by a pump to all parts of the engine, is very greatly affected by the viscosity of the lubricant. Since viscosity varies widely with temperature some control of oil temperature is necessary. During the cold period at starting, excessive pressures will be developed by the pump; and although these can be dealt with by relief valves, the flow to the bearings will be very small, and a long period of warming up is necessary until the flow is sufficient to allow full loading to be imposed on the bearings. When flying at low altitudes and in warm climates, and more especially with airship engines which are usually not open to any cooling air-stream, it is necessary to provide for cooling of the oil after it has left the engine.

The problem is a peculiar one, for although the amount of heat to be abstracted is comparatively small, the rapid rise of viscosity as the oil is cooled has the effect of producing a thick coating of viscous oil on any surface where cooling is effective. The conductivity of this viscous layer being very bad, the remainder of the hot oil passes on out of the cooler with a very inadequate reduction of its temperature. The problem is to prevent the oil, as soon as it is cooled, from remaining in contact with the cooling surfaces and so preventing the cooling of that which comes after. The problem will not be solved until a cooler has been designed which is light, which cools effectively and can deal with the high pressures developed while the oil is cold.

Water Recovery.—A problem peculiar to airships is that of compensating for the weight of fuel used during a long flight. In flying to Egypt a large ship would burn some 25 tons of fuel oil, and unless this weight can be made up in some way an equivalent quantity of hydrogen will have to be allowed to escape. An alternative is, while drawing liquid fuel from the tanks, to use less of this and to make up the balance of fuel required by drawing from the gas bags the corresponding weight of hydrogen necessary to maintain balance in regard to buoyancy. Research upon the use as fuel in an engine of a mixture of oil and hydrogen has yielded most promising results and this may prove the most workable solution of the problem.

The alternative of maintaining the dead load on the airship by condensing and storing the water in the exhaust gas from the engines is a matter of considerable difficulty, but it should not prove insuperable. With a water-recovery apparatus capable of cooling the exhaust gas to within 10° C of whatever may be the surrounding atmospheric temperature, and of collecting all the

water formed, the possible recovery should be from 0.9 to 1.1 times the weight of fuel burnt. This apparatus has for some time been working very successfully on big U.S. Naval airships. This is more important when helium is used, owing to the increased expense.

VI. FUTURE DEVELOPMENTS

Increase of Size v. Increase of Gas Pressures.—Apart from piston area and piston speed the only way of increasing the power of an engine is to increase the mean effective pressure. This can be done either by raising the pressure or lowering the temperature of the combustible mixture drawn in. The latter alternative has obviously only limited possibilities, but within these limits the use of fuels with high latent heat of evaporation, which therefore give more cooling of the charge, has been successfully applied in racing motor-car practice and may be also in aircraft engines. To raise the pressure of the mixture drawn in means the provision of a blower, not only to maintain ground pressure at altitude but to raise this pressure throughout above atmospheric. Under such conditions an engine of the same bore and stroke would have to have a heavier crank-shaft, connecting rods, pistons, etc., to stand up to the larger gas forces developed, the necessary blower and driving gear will be larger and heavier, the air coolers will be heavier and give more drag, so that it might be suggested that the extra power could be got at once by means of a bigger engine, *i.e.*, by more piston area, while leaving the gas pressures the same. Only the detailed calculation of weights and estimates of drag in the two cases can settle the question of which plan will produce the most effective engine, but the small engine with high gas pressure starts with an initial advantage so far as its own head resistance is concerned.

The Two-stroke Cycle.—To design for a working stroke every revolution is not the easy way toward reducing weight per h.p. which at first sight it appears. Getting the charge into the cylinder with only the limited area available for inlet valves is, at high speeds, one of the limiting conditions even when the time of half a revolution is available. If it has to be accomplished in one-third of the time, or less, the problem is proportionately greater. Any lowering of engine speed, if combined with all the extra weight of the necessary compressors for scavenging and delivering the fresh charge, may very soon bring down the extra horse-power per lb. from a two-stroke cycle to a very narrow margin. It is unlikely, moreover, that the same thermal efficiencies will be achieved as with the four-stroke cycle. Nevertheless the two-stroke cycle is a possible line of advance, more especially with the greater perfection of compressors for supercharging and in combination with the Diesel type of fuel injection.

Sleeve Valves.—One of the most difficult aero engine problems is the satisfactory operation of poppet valves at high speeds and high temperatures. The drawback to the use of sleeve valves has been, in the past, a tendency toward gas leakage, excessive oil consumption and large mechanical loss due to friction; but with the single-sleeve valve it is possible, by skilled design, to minimize these troubles, and this type of valve holds out extremely attractive possibilities. The absence of all springs in the first place and of the excessive accelerations which are so detrimental to cams, would at once eliminate a constant source of trouble. Moreover, the sleeve would necessarily be cool, so that tendency to detonation would be reduced.

The Compound Engine.—Forty per cent or more of the heat energy of the fuel is at present thrown away in the exhaust of a high-duty engine; where weight is no consideration some of this can be used for raising steam; but such methods of improving efficiency are probably out of the question for aircraft. The question remains, "Can some of this waste heat be saved by expanding the hot gases much further in a low-pressure cylinder?" The difficulty lies in the transfer of the hot gases at 1,000° C or more from the high- to the low-pressure cylinder. So long as this has to be controlled by poppet valves the difficulties are probably insuperable; no valves could be expected to stand up to such treatment, when it is remembered that they would need to be operated from outside, and that therefore there would be con-

tinuous leakage of hot gas down the valve stems where they slide in the guides. The only hope for the compound engine seems to be through the development of the sleeve valve.

Jet Propulsion.—More than one proposal has been made that the force for propelling an aircraft forward should be obtained by shooting out a jet of air behind, on the principle of the rocket. To obtain efficiency, however, when using this principle, it would be necessary that the forward speed of the aircraft should be of the same order as that of the jet backwards, while at the same time the drag due to air resistance has to be overcome by the reaction between the aircraft and the jet. The two conditions are incompatible. An alternative of greater possibilities is to have an air-screw which is rotated by jets at the blade tips and eliminates other driving mechanism, but this could never hope to achieve more than a very poor fuel economy when compared with a present-day heat engine. This has been proposed many times, both in water and air craft, but all tests have been so extremely inefficient as to border on the absurd. (D. R. P.)

The Diesel Engine.—Attempts made to solve the problems of the aircraft Diesel engine by refinements in design have been disappointing. The best that has been accomplished with water-cooled engines is 4.35 pounds to the h.p. The two stroke water-cooled engine is somewhat better due to recent advances in supercharger design, this showing 2.59 pounds to the h.p. But the air-cooled Diesel engine is down to 2.26 pounds to the h.p. by reason of a radical crank case and cylinder construction, and changes in air intake passages to increase the air charge and greatly augment the turbulence. These air-cooled Diesels have passed the rigid Government tests, and are in commercial production. One engine, produced commercially, developing 225 h.p. with its fuel pumps set for economy of operation, weighs 510 pounds.

In the experimental engines, the very greatly increased net mean effectives that can be obtained through supercharging are necessary to bring the weight down, but this immediately presents the difficulty of higher exhaust pressures, which brings into consideration compounding for the sake of economy. From work that has been pushed along this line for several years it would seem that the combination of the two last mentioned modifications is likely to bring the weight of the aero Diesel down to, if not under, 1.5 lb. per b.h.p. This, however, can only be achieved by carrying supercharging very much higher than ever before, and it is found that this is attended by no insurmountable difficulties. Difficulties were at first met, but these seem to yield to analysis and continued research. The great contribution of high supercharging is not only in greater mean effectives, but also in securing a shape and form of the combustion space that is many times more favourable than that of the comparatively minute crevice—on the order of $\frac{1}{20}$ the stroke only—constituting the normal Diesel clearance.

The lower cylinder temperatures of the Diesel as compared with the petrol engine allow of the single-sleeve valve being successfully employed, which, combined with the high supercharging pressure, introduces another very important factor—turbulence. This turbulence can be regulated and brought to an extremely high velocity, which is probably the most significant of all the gains. Not only is this velocity high at the moment of fuel injection at the end of the compression stroke, but it is found to persist throughout the remaining three strokes of the compound cycle. This has a three-fold significance. First, it allows the fuel to commingle with and finally reach a greater percentage of oxygen than has ever before been possible; secondly, it allows this process to go forward at very much higher speeds; thirdly, it ensures completeness of combustion, especially that fraction known as after-burning, which here takes place under conditions of extreme turbulence.

It is found that such an engine as this turns out to be $\frac{1}{14}$ two-cycle with very much higher net mean effectives to the crank for all power pistons than in two-cycle practice. The $\frac{1}{27}$ of the engine which remains four-cycle is performing an extremely useful function in producing the high velocity turbulence above referred to. In such an engine it is found that the negative work is only 1 : 42, accounting for the very high mechanical efficiency observed in this cycle.

The great advantages of the Diesel cycle in addition to those already referred to are: first, there is no difficulty in the distribution of fueling between the cylinders; secondly, the low fuel demand is extremely important in increasing the radius of flight or the pay load in commercial aircraft; thirdly, the complete elimination of all fire risk inasmuch as the fuel oil is not volatile. It is practically impossible to ignite it by any ordinary method and it will actually extinguish a small bonfire when dashed upon it. Besides this, it costs between $\frac{1}{3}$ and $\frac{1}{4}$ less and develops as much as 35% more B.Th.U.'s than "aviation gas," volume for volume. Fourthly, it does away with all of the electrical ignition complications and troubles, including spark plugs, together with the serious interference with wireless and radio reception.

AERONAUTICAL ARTICLES. The subject of aeronautics is treated in this work in the following series of articles. Under **FLIGHT, NATURAL**, will be found a study of natural flight, dealing with the mechanism of the bird's wing and the principles which underlie its use. From this the reader can pass to a general survey of artificial flying under **AERONAUTICS** and **AVIATION, CIVIL**.

The navigation and development of the balloon, and its transformation into an airship, can be studied in the articles **BALLOON**, **AIRSHIP** and **AIRSHIP SHEDS**.

Heavier than air flying machines are treated in the articles **AEROPLANE**, **BIPLANE**, **MONOPLANE**, **HELICOPTER**, **ORNITHOPTER**, **GYROPLANE** and **AILERON**.

Flying machines capable of alighting upon water are dealt with in the article **SEAPLANE**; in this connection the article **AIRCRAFT**—

For engine details see the articles **AERO-ENGINE**, **INTERNAL COMBUSTION ENGINES** and **AIRSCREW**.

The practical navigation of aircraft and their employment for various purposes can be studied in the articles entitled **AERIAL NAVIGATION**, **AIR-ROUTES** and **AVIATION, CIVIL**. There are special articles on the **PARACHUTE**, **AERODYNAMICS** and **AERIAL LAW**.

AERONAUTICS. The record of man's attempts to fly goes back into the remote past. The story of Icarus is a myth founded

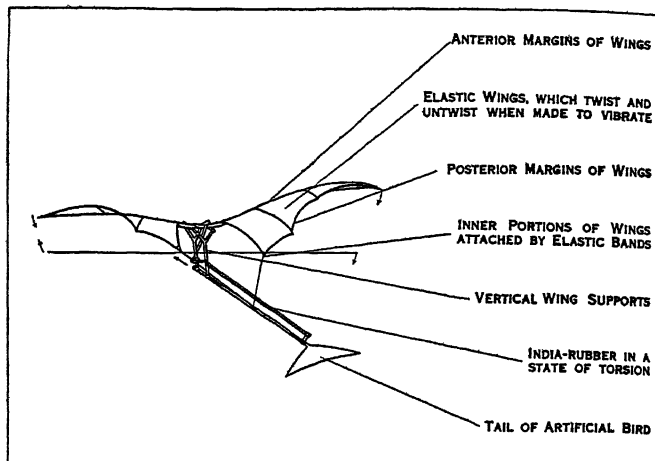

FIG. 2.—PENAUD'S SECOND MODEL WHICH WAS PROPELLED BY A SCREW AND SUSTAINED BY A HORIZONTAL FLEXIBLE WING. PENAUD'S SUCCESS OVER OTHER SIMILAR MODELS WAS LARGELY DUE TO THE INVENTION OF WHAT HE CALLED AN AUTOMATIC RUDDER, WHICH WAS A SMALL WING PLACED AFT OF THE MAIN WINGS

perhaps on some early failure to imitate the birds. Leonardo da Vinci thought and wrote about it, and there are some references to the subject in the works of Francis Bacon. In 1617, Fleyder of Tübingen lectured on flying; while in Italy, again, in his book *De Motu Animalium* (1680), G. A. Borelli discussed the question in connection with the strength of man's muscles and came to the conclusion that such flight was impossible.

Early History of Artificial Flight.—We are here concerned mainly with the flight of bodies heavier than air; for the early history of airships, see **BALLOON** and **AIRSHIP**. The first attempts, limited in all cases to the flight of models, were generally based on the endeavour to imitate the action of a bird's wings. Sir George Cayley, however, in 1796, constructed a tiny helicopter in which two windmills made of gull feathers were caused to revolve about a vertical axis. Figs. 1 and 2 illustrate two models due to Pénard, constructed in the early '70s of last century; in the first of these the motive power is obtained from a screw driven by the torsion of an india rubber cord; in the second an attempt is made to imitate the action of a bird's wings. Stringfellow in 1842 had already constructed a model in which the supporting force was obtained from the wings while the motive power came from a screw, and from that time on some of the fundamental principles underlying flight began to be more generally recognized.

FIG. 1.—PENAUD'S HELICOPTER OR SCREW-MODEL BUILT IN 1872. MOST OF THE PIONEERS IN AERONAUTICS DIRECTED THEIR ATTENTION TO THE CONSTRUCTION OF MODELS CAPABLE OF VERTICAL FLIGHT

CARRIER studies an important factor in the application of flying machines to naval warfare.

The question of aircraft terminals and accommodation is treated in the articles **AERODROME** and **AIRSHIP SHEDS**.

EARLY DEVICES OR PLANS FOR FLYING MACHINES, 1500 to 1843

1. Leonardo da Vinci's conception of a flying machine 1500. The wings or "oars" were to be operated by a system of stirrups or pulleys
2. Francesco de Lana's flying boat, conceived about 1650. The plan was to attach a boat with sails to four large copper balls from which the air had been exhausted
3. Combination of helicopter and aeroplane planned in 1809 by Sir George Cayley, spoken of as the father of British aeronautics
4. The "Eagle," designed by Comte de Lennox in 1834 in collaboration with Le Berrier; dimensions 130 feet by 35 feet with a lifting power of 6,500 pounds
5. Hand-driven propeller type navigable balloon experimented with in 1816 by Sir George Cayley
6. Henson's "Aerial" steam carriage, designed in 1842. The extensive supporting structures occupied a nearly horizontal position, and it was equipped with a 25-h.p. steam engine, but it never left the ground

NOTE:

Loading (lbs. per H.P.)—Gross weight ÷ Actual H.P. developed at normal revs. (A suffix R shows that Rated H.P. has been used in absence of Actual H.P.)

Lifting surface—Surface of wings and flaps only.

Military load—Weight of guns, bombs, ammunition and reconnaissance load (not crew).

Air endurance—At 10,000' alt.; at full throttle including climb, unless otherwise stated.

Service ceiling—Height at which rate of climb is 100 ft./min.

Weight empty—Includes cooling water in radiators.

Principles of Flight.—A bird's wings have two functions to perform; they support the bird in the air and they propel it forward. For an account of how this is done reference may be made to the article on FLIGHT, NATURAL. It would appear that support is given by the portions of the wing nearer the body, while the propulsive power comes from the more rapidly moving tips.

Imagine a flat surface in the form of a long rectangle, with its long edge horizontal and its surface inclined downwards from front to back, to be moved forward in a horizontal direction at right angles to its length. The pressure of the air on the under surface exceeds that on the upper; the plane thus experiences a force directed upwards and backwards. This can be resolved into one force, the "lift," acting vertically upwards, in a direction, that is, opposite to the weight of the plane, and into one directed backwards, the "drag," tending to stop the motion.

Measurement would show that approximately these forces are proportionate to the area of the plane and the square of the speed with which it is moved.

Now support on the plane an engine driving a screw propeller. If the motion thus produced be sufficiently rapid, the lift will exceed the weight of plane and engine, and, omitting for the moment considerations of balance, the plane will fly.

Early Mechanical Machines.—It was on principles such as these that machines were constructed by Henson in 1842 and Stringfellow in 1848. Stringfellow, in 1868, exhibited at the Crystal Palace a model for which he received a prize of £100. Langley, of the Smithsonian institute of Washington, worked on similar lines. It had been realized by this time that greater lifting power could be obtained by shaping the supporting surfaces correctly, *i.e.*, by giving them a convex shape on the upper side and a concave on the lower. A steam-driven model flew, in 1896, for a distance of about 1/2 m. along the Potomac river near Washington. At a later date, Langley built a large machine which was intended for passengers. It was fitted with a remarkably light steam engine designed by Manley and driven by two propellers; this was launched into the air from a vessel in the river. On each of the two occasions in 1903 on which it was tried, something went wrong with the launching arrangements and the machine was wrecked. Another early machine was that of Sir Hiram Maxim; this too was damaged in a trial in 1894.

Gliders.—Meanwhile, it had been realized that before success was reached more knowledge as to the conditions of balance in the air was necessary and, further, that much could be learned by the aid of gliders depending for their support on natural air currents.

The experimenters, suspended from their wings, jumped from natural or artificial heights and allowed the wind to carry them through the air. Lilienthal in Germany, who first showed the advantage of curved over flat surfaces, was killed after making over 2,000 safe flights; he endeavoured in these to maintain his balance by shifting his position relative to the wings. Chanute, in America, made the surfaces of the aeroplane movable; he constructed a number of machines.

The Modern Era.—Wilbur and Orville Wright, of Dayton in Ohio, began their epoch-making work in 1900 with gliders. They introduced two great improvements: the elevator, or horizontal rudder for steering the machine in the vertical plane, which they placed in front of the main planes (in nearly all modern machines it is attached to the tail); and the flexing of the rear edge of the main planes so as to vary the lift on either or both at will and thus maintain the balance in the air. A petrol motor driving a screw was added in 1903. In 1905 they made 45 flights, in the longest of which they remained in the air for half an hour and travelled 24 1/2 miles. A little later, 1906, Santos Dumont constructed a machine in which he flew a distance of about 250 yd. in 21 seconds.

In 1908, Henry Farman, at Issy-les-Moulineaux, made a circular flight of 1 km. and on Sept. 29 he covered 24 1/2 m. in 42 min. Meanwhile the Wrights had continued their work at Dayton. On Sept. 12, 1908, Orville made a flight of 45 m. in 1 hr. 14 1/2 min.; but a few days later he had an accident in which he was seriously injured and his passenger was killed. Wilbur Wright, on Sept. 21, 1908, at Le Mans, beat all previous records by a flight of 56 m.

in 1hr. 31min. 25 $\frac{1}{2}$ sec. On Dec. 31 he remained in the air for 2hr. 20min. 23sec.

These great advances had been rendered possible by the improvement of the petrol engine.

In 1909, a number of notable flights were made, several of them in monoplanes. On July 25 Bleriot crossed the Channel from Calais to Dover, and later Latham nearly achieved the same feat.

In November, Farman covered a distance of about 134 $\frac{1}{2}$ m. in 4hr. 17min. 53sec.

Next year Paulhan, at Los Angeles, in a biplane, reached a height of 1,383yd. and on April 27-28, 1910, the same pilot won the *Daily Mail* prize of £10,000 by flying within 24 hours from London to Manchester with one stop.

Table I., printed herewith, gives some details, approximately correct, of the principal experiments made with flying machines from 1879 to Wilbur Wright's flight in France.

Since that day the advance has been enormous. In place of the toy models of Henson and Stringfellow we have machines weighing as much as ten tons with a wing span of 70-80ft. and speeds rising to over 100m.p.h., and in a machine such as that which won the Schneider cup in 1927 far in excess of this, driven in some cases by twin or triple engines aggregating from 900 to 1,000h.p.

For details of British Service aircraft see Table II. on page 243. See also TRANS-OCEANIC AND TRANS-CONTINENTAL FLIGHTS.

THE SCIENCE OF AERONAUTICS

The year 1909 opened a new era in the history of aeronautics. Towards the end of 1908, the Wrights had made their flights. The value of the aeroplane as a weapon became obvious; how valuable, it was left for the World War to show. Little was known of the forces affecting aircraft in motion; of the laws regulating the flow of air in their neighbourhood; the conditions required for balance and safety; the relation between the form and dimensions of the supporting planes and the weight carried; or the mechanism necessary for the control of the machine in flight.

The internal combustion engine had made flight possible, but the way to combine efficiency and lightness was but vaguely understood. The propeller brought problems of its own; naval architects had made a study of the action of the screw in a ship; to what extent did the conclusions they had reached apply to an airscrew? It was clear that there was much to learn and many directions in which research and experiment, conducted under proper supervision, could help.

Experiments in aerodynamics had been made by Langley in 1891. Zahm at a later date (1902-03) had measured the air velocity, pressure and friction on surfaces of various forms. Stanton, at the national physical laboratory, had experimented on the resistance of surfaces in a current of air and the pressure of the wind on plates. Lanchester, in his *Aerodynamics*, had described similar measurements. Lord Rayleigh, in various papers of great importance dating from 1876, had discussed questions of the resistance of fluids and, in 1899, contributed to the Manchester Memoirs a paper on the mechanical principles of flight; but no organized attack on the questions raised by the flight of a body heavier than air had been made.

Abroad, the airship had attracted more interest. In 1906 the society for the study of airships was formed in Germany, divided into branches dealing respectively with meteorology, dynamics, construction and engineering. Their first report, March 1907, describes in full detail programmes of the work proposed in these various branches; specially interesting is the account it gives of the method of testing resistance to the motion of an airship by means of a model in a wind tunnel and other proposals by Prof. Prandtl for testing model airships by means of towing by automobile.

Advisory Committees for Aeronautics.—Early in 1909, R. B. (later Lord) Haldane suggested that a section devoted to research in aeronautics might be established at the national physical laboratory. In May of that year the prime minister, H. H. Asquith, announced that this had been done and that, for the superintendence of the investigations and to advise on scien-

tific problems arising in connection with the work, he had appointed a special committee—the advisory committee for aeronautics.

Meanwhile, work of a similar character was in progress elsewhere: at Göttingen, under Prandtl; at Koutchino in Russia, where Riabouchinsky was director; at a somewhat later date in America under the national advisory committee for aeronautics; and in Italy by Crocco; while papers on stability had been published by B. F. Lanchester and Soreau.

Aerodynamics.—In studying the forces to which aircraft are subject in flight, mathematics alone are of but little help; the dynamics of the air are too complex for a complete theory, and recourse must be had to experiment.

In the case of a body heavier than air an upward force, or lift, must be provided which, when the motion is horizontal, will just balance the weight. As the aircraft moves forward various actions produce a resistance to its motion, and unless a force is provided to balance that resistance, the drag on the machine, it will come to rest; the mechanism must provide a propelling force which for uniform speed must just balance the drag.

Now we have seen already that when a flat surface inclined at a small angle to the direction of motion is moved forward through the air it experiences a resistance—drag—opposing the motion and a force—the lift—at right angles to that motion.

To carry a given weight how large must this surface be, at what speed must it move and at what angle to the direction of motion should it be placed? What will be the resistance to its motion and what horse power must be supplied? What is the best form of surface for the purpose both in section and in plan? How must matters be arranged so as to secure controllability and reasonable safety to the flyer? Such were some of the questions to be answered.

Since 1909, many, perhaps all, of these and similar questions have been answered in part by observation and experiment on full scale machines, in part by the use of suitable models in a wind tunnel.

The Wind Tunnel.—W. Froude had shown that by towing the model of a ship in a tank and measuring the force required to tow it, the resistance to the motion of the ship at sea and the horse power required to propel it could be calculated.

In tank experiments the model is towed through water, but the problem is one of relative motion. If it were possible to obtain

FIG. 3.—DIAGRAM SHOWING RESULTANT OF LIFT AND DRAG ON A FLAT RECTANGULAR SURFACE

a steady stream of water free from eddies and turbulence, the model might be stationary and the water stream past it. This was the method adopted by those investigating the pressure of moving air on surfaces exposed to its action. Arrangements were devised to produce a steady flow of air through a closed channel and measure its speed. The model was placed in this stream and attached to a balance specially designed to measure the forces acting on it.

Imagine the air stream in the tunnel to be horizontal, and take as an example a narrow rectangular plate placed with its longer edge horizontal and at right angles to the direction of the wind and its plane inclined at a definite angle to the same. This angle is known as the angle of attack. The balance is such that the horizontal force or drag, the vertical force or lift at right angles to the wind direction, and couple tending to turn the model about an axis parallel to its length can all be measured. The last observation enables the position of the centre of pressure, or point in which the resultant of the wind forces intersects the model, to be determined.

For fig. 3, *ACB* represents a section of the model by a vertical plane through the wind direction. *C* is the centre of pressure through which acts the resultant force; the balance measures its components, the lift, the drag, and also the couple tending to rotate the model about an axis perpendicular to the paper through some point depending on the attachment to the balance.

Details of the various forms of wind tunnel in use and of the balances and their method of attachment to the model will be found in the article on AERODYNAMICS, to which reference should be made.

It is found that, so long as the angle of attack remains the same, the lift, the drag and the couple are approximately proportional to the product of the density of the air, the square of its speed and the area of the surface on which it acts; so we may write

$$L = K_L \rho S V^2$$

$$D = K_D \rho S V^2$$

$$M = K_M \rho S V^2$$

when M represents the couple; the coefficients K_L , K_D , K_M are constant so long as α the angle of attack is not varied; ρ is the air density, S the area of the plane and V the air speed.

The three coefficients depend on the angle of attack; by making observations at various inclinations of the surface to the wind we can draw a curve for each of the quantities L , D , M and thus read off their values at any angle of attack.

Scale Effect.—But this is for the model. How can we step from it to the actual machine? Froude had shown that for a ship there was a definite relation depending on the size and speed of model and ship. Lord Rayleigh investigated the condition, which must hold in order that the motion of the air round the model should be similar to that near the machine. He found that, assuming the medium in which the motion takes place to be identically the same in both cases, the condition was expressed by the statement that vl should be the same for model and machine, v being the speed and l some length determining the scale in each case. Now, clearly this condition cannot be satisfied; for both the speed and size of the model are necessarily less than those of the machine itself. Experiment, however, has shown that in many cases it is not necessary to fulfil the strict condition; we may apply the equations already given to the machine using the value of the coefficients, K_L , etc., found from

FIG. 4.—CHART OF LIFT COEFFICIENT SHOWING IN ADDITION TO THE LIFT AND DRAG CURVE, THE RATIO OF THE LIFT TO THE DRAG

the model experiments. Still, there are numerous problems in which this scale effect is of importance, and for discussion of these reference must be made to the article AERODYNAMICS.

Lift and Drag.—The curves for lift and drag depend on the form of the aerofoil under test. For a given incidence the value of K_L , the lift coefficient, will be much less for a plane surface than for a wing of good form. Fig. 4 gives the curves for a wing,

while in fig. 5 are shown some wing sections. In addition to the lift and drag curves, the ratio of lift to the drag is also plotted and it will be noted that this has a minimum value for a low angle of incidence and increases somewhat rapidly with the incidence. The lift, it is true, increases up to a certain value as

FIG. 5.—TYPICAL WING SECTIONS
(1) R.A.F. 15. (2) R.A.F. 32

the angle of attack is increased; but the drag increases more rapidly. Thus, while a much greater lift is obtained by increasing the angle of the planes to the horizontal the thrust given by the airscrew necessary to do this increases in a much more rapid ratio.

Stalling.—The curves for different shaped wings are different and, while we may note that increasing the camber of the upper surface within limits increases the lift, reference for the detailed effect of the shape of the section on the properties of the wing must be made to the article AERODYNAMICS. All curves of the lift have one property in common. As the angle of attack increases still further the lift suddenly falls; the aeroplane can no longer fly; its power to carry its load has gone and it must fall; it is said to be stalled. If the engine power be sufficient to maintain the speed, then by increasing the angle of attack at which the machine is flown the weight carried can be increased, or alternatively, if the load remain the same while the angle is varied, the speed can be reduced, until at last a limit is reached, the stalling angle is exceeded and the machine becomes uncontrollable and falls.

A very large proportion of the accidents which occur arise from this; it may be an engine failure or a lapse on the part of the pilot causing him to attempt a turn when going at too slow a speed; the machine is stalled at too low an altitude and falls; before control can be regained it strikes the ground and is wrecked.

Wind Tunnel Results.—For a full discussion of the equations giving the lift and drag and the consequences to be deduced from them reference must be made to AERODYNAMICS. A few of the more obvious consequences may be mentioned here.

Besides its wings, an aeroplane has a tail and elevator, a body fitted with a fin and rudder, an engine and airscrew, with tanks for petrol and oil; all of these contribute to the drag and some to a small extent to the lift, but neglecting these, let us see what conclusions we can draw directly from the equations.

When an aeroplane is flying horizontally at uniform speed the total lift will just balance the weight W . The lift is mostly carried by the wings; so neglecting for the present the effect of the tail and body we have the result that the weight carried is found by multiplying together the lift coefficient, the density of the air, the area of the wing and the square of the speed.

The loading, the average weight carried by each unit of area of the wings, will be given by dividing the quantity by the area of the wings.

Again, the conditions which must be satisfied if the machine is to climb well can be worked out, and we see how experiments in the wind tunnel can be utilized to predict the performance of the machine.

Conditions for Stalling.—Before passing on to consider other problems, it will be useful to look a little further into the question of stalling. Observations in the wind tunnel made by the aid of smoke or in a water channel show that for a wing of good shape, flying at a small or moderate angle of incidence, the motion of the air is approximately stream line; it flows smoothly past the wing, there is very little eddying or turbulence. As the incidence is increased the eddies formed behind the wing increase also and for a time the lift and drag increase until a condition of affairs is reached in which there is little or no semblance of stream line motion; the wake behind the wing is a mass of turbulent eddies; the drag is very large while the lift falls and is quite uncertain as to its value.

The changes outlined are illustrated by the figures 6 and 7. The figures show too why the drag increases as the incidence

becomes larger. It is known that in a frictionless fluid, and air is nearly frictionless, there would be no resistance to the motion of a body of stream-line form, a body that is, round which the air would flow in stream lines without eddies; that in any actual case there is some small resistance is due to the slight friction between the body and the air; but when the motion becomes turbulent, energy is necessary to support the turbulence and some of the power required to propel the body is used in supplying this energy; the drag on the body is increased and more power is needed to maintain the speed.

Stability.—Before turning to this section of our subject it is necessary to consider what is meant by stability.

A pendulum, such as a ball hung by a string, or a rod balanced vertically on a finger, when at rest, are both in equilibrium. So long as they are undisturbed the rod and the string both remain vertical, but the effect of a slight disturbance differs in the two cases; if the pendulum be disturbed it oscillates about its equilibrium position for a short time, finally coming to rest as before; the rod when disturbed falls to the ground unless by skilful movements of the finger it is possible to restore the balance. The pendulum exemplifies a case of stable equilibrium, the rod of unstable; similar considerations apply to a body in a state of steady motion, an aeroplane (say) moving horizontally with constant speed. Imagine that by some means—a sudden downward gust for example—the motion is slightly disturbed and the nose takes a downward direction. Suppose too that the pilot does nothing to counteract this, then two things may happen, the nose may rise again—of its own accord as it were—and after a few oscillations up and down the machine may recover its horizontal path. Like the pendulum it is stable, it can be flown without touching the controls, unless of course the initial disturbance is too violent. When the engine has once been adjusted to give the power necessary to maintain horizontal flight at the specified speed the machine will continue to fly thus of itself. On the other hand, the initial disturbance may increase, the nose may continue to drop, the machine like the rod on the finger is unstable and action is required on the pilot's part in order to recover the steady horizontal flight. It is not possible here to discuss the conditions necessary for stability; it must suffice to state that they require the knowledge of a number of quantities known as stability derivatives which can be determined by suitable experiments in an air tunnel.

1810
FIG. 7.—EDDIES FORMED IN THE WAKE OF A FLYING WING
The increased angle of incidence of the wing to the air current creates appreciable air eddies

As to the relative advantages of stability and instability much might be written; stability brings with it consequences which for some purposes are disadvantageous. The machine has, as it were, a will of its own, once set to a certain course it tries to keep to it; it is less easy to manoeuvre, to be deflected by the pilot from its course and forced into the sudden changes of motion and aspect needed, say, for military purposes.

For a fighting machine too great stability is a disadvantage; on the other hand, for a civil machine designed to go from one aerodrome to another at a given speed, stability is a marked advantage; it adds to the safety of the aircraft and it diminishes greatly the strain on the pilot.

Modern Theories.—So far, we have been discussing the elements of aerodynamics and the manner in which wind tunnel experiments may be used to determine the characteristics of a machine.

Reference must be made to the article on AERODYNAMICS for a description of the various forms of wind tunnel now in use,

FROM "THE TECHNICAL REPORT OF ADVISORY COMMITTEE FOR AERONAUTICS," 1912-13, BY PERMISSION OF H. M. STATIONERY OFFICE

FIG. 6.—EDDIES FORMED IN THE WAKE OF A FLYING WING

This shows the minimum air disturbance when the plane is inclined at a small angle to the wind and the motion is effectively "stream-line"

and an account of how, following up some very early work by Lanchester the lift and drag of an aeroplane wing have been derived in the first instance by Prandtl and his school at Göttingen, from the fundamental equations giving the circulation set up in the air around the wing and the vortices shed from its tips and trailing edge. Much work on the same lines has been done under research committees working in England and America. Fig. 8 (p. 247) shows the usual form of wind tunnel adopted in Great Britain.

THE AEROPLANE

Fig. 9 on p. 247 gives a diagram of an aeroplane indicating its principal parts and their names.

The main purpose of the various parts is clear from the figure which represents a biplane; the wings support the machine; to secure steady motion in a vertical plane a *tail plane* is necessary, and in order that the motion in that plane may be controllable part of the tail is hinged and can be raised and lowered thus forming the *elevator*.

Steady motion in the horizontal direction calls for a *vertical fin* at some distance behind the main planes and, to control the direction of that motion, a *rudder* is added to guide the machine.

The tail plane and fin are connected to the wings by the *fuselage*, in the fore part of which is the *cockpit* containing the pilot's seat and the controls. A portion of the rear extremity of each wing is hinged about an axis parallel to the length of the wing, thus forming an *aileron*. Lowering an aileron increases the angle of incidence and therefore the lift of that portion of the wing; raising it has the opposite effect. The pilot is thus able to control any rocking of the aeroplane about a longitudinal axis.

Control wires pass from these movable parts to the pilot's seat, those from the rudder going to the *rudder bar* worked by his feet, while those from the elevator are connected to the *control column* or *joy stick*, a rod fixed in front of the pilot by a universal joint at its lower end. The connections are such that the longitudinal motion of the column raises or lowers the elevator while a transverse motion affects the aileron.

In a *tractor machine*, as shown in the drawing, engine and air-screw are in front of the pilot; in a *pusher machine* they would be placed at his back. The planes are connected by *struts*, while rigidity is secured to the structure by a series of wires arranged to keep the two planes in fixed relative position. The *longerons* are the lower main members of the body structure which are prolonged forward so as to support the engine; the machine is carried on the *landing chassis*, an under carriage on wheels fitted with springs so as to absorb shock on landing. At the rear is the *tail skid*, which rests on the ground when taxiing.

The distance between the wings is the *gap*. In many machines the upper wing is not set exactly above the lower but either rather in front when the machine is set to be positively *staggered* or behind when the stagger is negative.

In a *monoplane* there is only one pair of wings.

Details of Structure.—We turn now to the actual design and structure of aircraft, remembering that a fuller account appears in the article AEROPLANE.

For most purposes the design must be such that the aeroplane will fly safely with a minimum expenditure of power. Since the total weight carried is fixed, the structure must be light in order that the useful load, that part of the load not made up of the weight of the machine including the engine, petrol, oil and necessary equipment, may be as large as possible; the machine must be controllable; the stability and manoeuvrability desirable will depend on the purposes for which it is required.

Landing is made more easy if the speed is slow, hence the stalling speed, the minimum speed of flight, should be kept as low as other requirements permit; precaution against fire should be taken, and, for a civil machine, the comfort of the passengers is of great importance; the noise inseparable from a high powered engine is most trying; and steps should be taken to reduce it whenever possible.

In the earlier machines the main structure was of wood and the wings were covered with linen cloth painted or doped with a kind of varnish to secure stiffness and protect the material.

FIG. 8.—WIND TUNNEL AT THE NATIONAL PHYSICAL LABORATORY, TEDDINGTON, ENGLAND, ILLUSTRATES THE FORM USUALLY ADOPTED IN GREAT BRITAIN FOR CONDUCTING AERODYNAMIC EXPERIMENTS

In more modern machines much of the main structure is of metal, while in a few, particularly sea-planes and flying boats, metal in the form of a thin sheet is used for the covering of the wings. The need to combine lightness and strength in aircraft has led to much metallurgical and engineering research, and by the use of new alloys many desirable changes in the structure have become possible.

The functions of the various parts of the machine are discussed in full detail in the article **AEROPLANE** and their use in controlling the flight at the will of the pilot described.

Prevention of Stalling.—By these means, so long as the machine has sufficient speed to produce the necessary lift, it is under control: but, if from any cause stalling incidence is passed, the lift is suddenly reduced, controls cease to be fully effective and the machine falls rapidly. If this takes place at a sufficient altitude the pilot may be able to put the machine into action, thus increasing the speed and bringing the controls into full play again or, on the other hand, the machine may develop a spin, which it is difficult to stop, and be wrecked, before the pilot can regain control.

Now we have seen that the stalling speed is inversely proportional to the maximum lift coefficient. By increasing this, we reduce the stalling speed, *i.e.*, we enable the machine to be flown at a speed at which it would otherwise be uncontrollable. Various attempts have been made to put it into the power of the pilot to increase the lift in case of emergency; the *Handley Page slot* is one of these. This consists of a slot or narrow aperture cut in each wing, parallel to its length; the slot is ordinarily closed but the pilot has the means of opening it and thus the lift is increased. In a more recent form, also due to Handley Page, the slot opens automatically when stalling incidence is passed.

The use of the slot alone has certain concurrent disadvantages. These, however, can be overcome by a suitable adjustment of the ailerons, and mechanism has been devised combining the two, so that when the slot is opened the ailerons simultaneously take up the correct position.

Fig. 10 (p. 248) shows a wing fitted with a Handley Page slot.

Loading: Load Factor.—In a modern engineering structure the stresses to which each component member will be subjected can usually be calculated and the necessary strength provided. In an aeroplane the stresses depend on the velocity and acceleration of the machine, its position in the air, the gusts of wind to which it may be subjected, etc. While it is possible to calculate them for steady horizontal flight and for certain other definite conditions of motion, the calculation cannot take account of all possible conditions.

To allow for this a load factor determined as the result of experience is assigned to each member of the structure; the calculated stress, including as usual a factor of safety, is multiplied by the load factor and the result is the stress which the member is designed to bear.

METHODS OF PROPULSION

The failure of the early attempts to fly was due in no small degree to the want of a proper engine; there was little knowledge of the power necessary. Models were devised, worked by india-rubber cords or clockwork, and in 1842 Phillips built a steam-driven model which, according to his account, rose to a great altitude and flew across two fields. Steam was used by Henson (1843), and Stringfellow (1847), who, in 1868, obtained a prize of £100 at an exhibition of the aeronautical society held at the Crystal Palace. The engine was estimated to give $\frac{1}{3}$ horse power.

FIG. 9.—MODERN AEROPLANE SHOWING STRUCTURAL PARTS

The weight of the complete model was under 12 lb. and the area of the wings and tail about .36 sq. feet.

The steam engine used by Langley (1903) was remarkable; it was designed by Manley and its weight was extremely small for the horse power produced.

In his earlier model the weight of the engine was 60 oz. and the power developed 1 h.p.; the four boilers weighed 7 lb. each.

Maxim, in his experiments of 1894, employed a pair of two-cylinder compound engines, each weighing 600 lb. and giving 363 h.p.

The whole problem was changed by the invention of the internal combustion engine burning petrol.

Santos Dumont employed a light and powerful petrol engine in 1906; about a year later Henry Farman used an eight-cylinder Antoinette petrol motor developing 40 h.p. at 1,100 revolutions per minute.

In 1908, Wilbur Wright, in his notable flights in France, employed a four-cylinder petrol engine of 24 h.p., making 1,200 revolutions per minute and connected by chain gearing to two wooden propellers which revolved at 450 revolutions per minute. The weight of this motor was stated to be about 200 lb.

Engine Requirements.—From this time onward progress has been rapid and reference should be made to the article on AERO ENGINES for the details. The problem for the designer has been to reduce the ratio of weight to horse power; and this implies not merely a reduction in the weight of the engine itself but also in that of the fuel consumed.

While an engine of 450 h.p. may weigh 900 lb. or 2 lb. per h.p., the fuel it uses may amount in four hours to about the same amount; thus, while the engine weighs 2 lb. per h.p. the power unit—engine and fuel for a four hours' flight—comes to 4 lb. per h.p.

Again, in the design of an engine, attention must be paid to its head resistance; the aeroplane itself, with its wings, body and under carriage, offers considerable resistance to the motion, and this is increased in a marked degree, unless great care is taken in the design, by the resistance due to the engine itself, placed as it usually is in the extreme front of the machine. In designing a machine it is clearly of great importance to have regard to the engine with which it is to be fitted.

In the endeavour to combine lightness and power many problems await the designer; thermodynamic reasoning shows that the efficiency—the ratio of the energy given to the propeller to the heat, measured as energy, supplied to the engine—increases as the compression in the cylinder is increased, but too great a compression produces detonation—knocking—in the engine, and delicate experiments are required to investigate the cause of this. Something has been done recently by the introduction into the fuel of chemicals—dopes—which in some way reduce the tendency to detonate and permit a higher compression to be used, but the method of action of the dope is by no means clear, and requires further investigation.

Another difficulty arises from the high temperatures involved. A material is needed which will combine strength and the power to resist great heat, especially in the moving parts, the valves and valve spindles exposed to the outrush of the exhaust gases. Some of this difficulty may be met by sleeve valve construction.

The sparking plugs, again, are a source of difficulty; every motorist knows of the trouble caused from time to time by a faulty plug. In a modern high-power aero engine the troubles are multiplied many times, and much care and thought are being spent in devising improvements.

Petrol is a source of danger, and for airships especially the use of a high compression engine of the Diesel type would have marked advantages. Such an engine, if light enough, would also be of undoubted value in an aeroplane.

FIG. 10.—A WING FITTED WITH A HANDLEY-PAGE SLOT TO PREVENT STALLING WHILE FLYING AT A SPEED AT WHICH THE PLANE WOULD OTHERWISE BE UNCONTROLLABLE

Power and Height.—The energy fed into an engine comes from the combustion of the oxygen drawn into the cylinder at each alternate stroke of the piston, and the volume drawn in is the same whether the engine be on the ground or at an altitude. But the air density falls as the machine rises. The quantity of oxygen ready for burning in each stroke is thus reduced and the power of the engine falls off. The exact proportion in which this occurs varies with different engines, but approximately the power is proportional to the density of the air drawn into the cylinder.

Supercharging.—To remedy this a device is added in certain cases whereby the density of the air supplied is maintained constant; this takes the form of a blower or pump which forces into the cylinder more air than would normally be drawn in; the engine is said to be supercharged.

Carburation.—The petrol is supplied to the engine through the carburetter and the amount of petrol needed for most efficient working depends on the amount of air drawn in; the ratio of petrol to air should remain constant.

Thus, as the machine rises and the air density falls, it is desirable to reduce the supply of petrol proportionately. Various devices have been proposed to do this automatically, none, however, completely successful, and as the result there is commonly a very considerable waste of petrol.

Flow Meters.—The pilot has no ready means of knowing the rate at which petrol is being supplied, and for this a suitable form of meter to indicate the flow is highly desirable.

Modern Engines.—The article AERO ENGINE indicates how these numerous requirements are being met; the splendid success achieved by the makers of the engine which won the race for the Schneider cup in 1927 is some measure of the advance that has been made.

Aero engines fall into two main classes: (1) water-cooled and (2) air-cooled; in the one the cylinders are cooled as in an ordinary motor car engine by water which circulates round their jackets and is itself cooled by passing through the radiator, placed usually in the extreme front of the machine, but in the case of modern extra high speed aircraft in the wings.

For an air-cooled engine, the outside of each cylinder is fitted with a number of webs or flanges, thus increasing the cooling surface, and the engine itself is placed in a position in which it is exposed to the full draught of air around the machine. It acts as its own radiator.

The air-cooled engine again falls into two classes; in the one the cylinders are fixed, the motion is conveyed to the airscrew by the shaft; in the other the cylinders rotate about a fixed shaft and carry the propeller round. Details as to a few typical engines are given in Table III. on p. 249.

THE AIRSCREW OR PROPELLER

The use of a screw as an instrument of propulsion has long been familiar, and various theories have been proposed to account for its action.

The earliest of these, due originally to Froude and Rankine, is known as the momentum theory; the screw is regarded as a disk which in some way imparts momentum to the column of fluid which passes through it.

Imagine the machine to be at rest and the air where uninfluenced by the screw to be approaching it with velocity V .

In reality, of course, the air is at rest, and the machine moves forward with velocity V_1 but the forces brought into play are identical in the two cases. The velocity of the column of air which passes through the airscrew disk—the area of the circle swept out by its blades—is increased according to Froude by an amount v so that the column leaves the screw with a velocity $V+v$. It follows as a further consequence of the theory that half the additional velocity is acquired before the screw is reached. So that the velocity with which the air arrives at the screw is $V+\frac{1}{2}v$.

Thus we have a column of air of density ρ and area of cross section A approaching the screw with speed $(V+\frac{1}{2}v)$ and the mass which traverses the disk in 1 sec. will thus be $A\rho(V+\frac{1}{2}v)$. This mass gains a velocity v and the momentum generated in one second is $A\rho(V+\frac{1}{2}v)v$. This must be the force exerted by the

screw on the air and therefore the thrust or force driving the screw through the air.

The Aerofoil Theory.—A more modern theory regards the action of a screw as an aerofoil or aeroplane wing in rapid rotation about one end. An aerofoil moving forward in a straight line at right angles to its length experiences a lift perpendicular to the direction of motion and a drag opposing the motion.

Imagine now that the aerofoil, instead of moving uniformly forward, is spinning about one end round an axis parallel to the direction of lift, a similar result will follow, each section perpendicular to the length of the aerofoil is moving forwards, though with a velocity which varies as its distance from the axis; each section therefore experiences a "lift" parallel to the axis and a "drag" acting so as to check the motion of rotation.

The lifts combine to produce a resultant thrust on the aerofoil in the direction of the axis, the drags to form a torque about the same. To maintain the motion a torque must be applied sufficient to overcome the drag and the action of the aerofoil transforms the torque into a thrust on the air. We have an elementary screw.

In order that the thrust may act along the axis and not at a point on the aerofoil which changes its position as the blade rotates, a second aerofoil is added on the other side of the axis and with its front edge pointing in the opposite direction to that of the first.

Again, if the blade were of the same section from root to tip, since the tip is moving very much faster than the root, the thrust on an element at the tip would greatly exceed that near the root. To obtain a more uniform grading of the thrust the shape of the blade is altered as we pass from root to tip in such a way that the angle of attack, the angle between the blade and the direction of motion relative to the air, is greater at the root than the tip and thus we arrive at the two-bladed screws in common use.

Reference has been made in the section dealing with aerodynamics to the vortex theory of the aerofoil; this theory has been applied by Glauert to the action of the airscrew with results which explain most of the outstanding difficulties of the earlier theories.

Airscrew Efficiency.—The above account will serve to show in a general way how the energy supplied by the rotation of the engine is transformed into that required to drive the aircraft; by the efficiency of the screw we mean the ratio of the power developed as thrust to the horse power delivered by the engine.

To utilize the power of the engine to the greatest advantage the pitch of the airscrew employed should change with changes in the speed of the machine; for if an airscrew be designed to be most efficient when the engine is running at its normal rate, and the machine flying at full speed, it follows both from theory and experiment that when stationary on the ground the rate of rotation is very appreciably less than that required for efficiency under these conditions and the airscrew is not giving its full thrust; it would be an advantage then to vary the pitch of the screw so as to permit the engine to exert full power on the ground as well as when in flight at various altitudes; efforts are being made to discover a satisfactory solution to the engineering difficulties involved.

In general, airscrews are made of hard wood, but in a number of cases metal has been employed and is likely in time to supersede the use of wood. Fig. 11 gives a drawing of a typical airscrew.

NAVIGATION AND INSTRUMENTS

The pilot has to find his way in the air as well as control his machine, and for this, like the sailor, he needs special instruments. These are fixed to the dash board of his cockpit.

Here it must suffice to refer to the more important of these, but before doing this, a difficulty peculiar to flight when the horizon is invisible and the ground cannot be seen, must be noted.

Finding the Vertical.—The pilot, then, has no means of determining the vertical or of knowing for certain whether he is flying straight or in a curve. When the machine is at rest on the ground the bubble of the level fixed in the machine at right angles to its length occupies its central position or a pendulum, a heavy bob suspended from some point in the machine hangs vertically. The same is true if the machine is moving horizontally at uniform speed. Again, if the machine still moving in the same way rolls over to one side the pendulum swings to that side and the pilot can correct the list by the proper use of his controls.

But suppose the machine begins to turn in a horizontal plane (say) to the left. The pendulum bob swings outwards to the right until the direction of the string lies along the resultant of the weight and the centrifugal force now acting on the bob. The pilot, ignorant of the change to curved motion, alters his controls to bring the bob back to its central position, thinking thereby to put the machine on even keel. Instead of this, however, he has nearly given the machine the "bank" appropriate to the curve in which he has commenced to fly and proceeds to describe a circle.

Turn Indicator.—To avoid this difficulty an instrument known as a turn indicator has been devised, and this warns the pilot when his machine begins to deviate from its straight course. By the aid of a compass and a turn indicator he can maintain his direction.

Compass, Altimeter, Speedometer and Gauges.—The compass has its own difficulties and for a discussion of these reference must be made to the article on AERIAL NAVIGATION.

FIG. 11.—AIR SCREW OR PROPELLER

To know his height or to fly at constant height the pilot uses an altimeter, a form of aneroid barometer specially designed and corrected for his use (*see* ALTIMETER).

The speed is given by the speedometer, which acts on the principle that the pressure on a surface opposed to wind of velocity V exceeds by $\frac{1}{2}\rho V^2$ that on a surface tangential to the direction of motion. A rotation counter registers the engine revolutions, while there are gauges to indicate the quantity of petrol in the tanks and the temperature of the water in the radiator system.

Sextant: Wireless.—To determine his latitude and longitude when over an unknown country or at sea he must use a sextant and a chronometer. The horizon is often invisible; this and the unsteady movements of the machine make the use of an ordinary sextant difficult, and the R.A.F. bubble sextant has been devised to overcome these.

Wireless telegraphy also comes to the navigator's aid and, when in touch with direction finding stations, enables him to fix his position.

Instruments for Research.—For research work, the measurement of the forces on the various parts of an aircraft in flight due to the pressure of the air and to its rapid changes of motion, many most valuable recording instruments have been devised, some of which will be found described in the appropriate sections.

Seaplanes and Flying Boats.—For seaplanes and flying boats *see* SEAPLANE.

The Hump Speed.—As the speed increases from rest when starting, the resistance on the hull increases rapidly until a certain speed known as the *hump* speed is attained. When this is passed there is a marked drop in the resistance and the machine rises and planes or skims over the surface, the speed increases until the lift on the wings is sufficient to carry the weight, and the aircraft rises from the water and continues its flight through the air. The determination of this *hump* speed and the proper adjustment of airscrew and engine to attain a full efficiency at this speed constitute a serious problem for the designer. Much work has been done in the William Froude tank at Teddington on seaplane problems, the conditions of stability, the form of float or boats, the hump speed for various designs, the strength obtained by the different methods of construction and other important matters have been investigated in co-operation with the officials of the R.A.F. station at Felixstowe, while observations in the wind tunnels have been of the utmost value in reducing the air resistance. The great speed attained in the Schneider cup race of 1927 was due to changes in shape made in consequence of such experiments. (*See* TRANSPORT BY AIR.) (R. T. GL.)

AEROPLANE. The main problem that confronts the designer of any means of transport is to find a working compromise between the various demands of those who maintain and use the service. There is no conflict between the interests of the operator and those of the user. Their common requirements are safety, speed, comfort and adherence to a published time-table. While it cannot yet be maintained that air transport is either as safe, or as comfortable, or as reliable as most other comparable methods, it has nevertheless achieved much in these respects, and in speed and the possibility of uninterrupted transit it has advantages which no other means of transport can equal.

In speed the aeroplane starts, broadly speaking, where the fastest alternative leaves off. For reasons which are explained in the article AERODYNAMICS a normal aeroplane cannot be maintained in flight at a speed less than a certain minimum "stalling" speed, which for a modern commercial aeroplane varies between 40 and 65 miles per hour. On the other hand, it is possible to give it an engine powerful enough to drive it at between 90 and 140 m.p.h., while leaving a margin of some 25% of its total weight for passengers or goods. The aeroplane's permanent way, the air, is the only medium of transport which connects without interruption all places on the globe. It may be anticipated that the consequent possibility of transit free from "changes" may prove to be as valuable as the speed which can be maintained.

The cost of air transport is high and it is in terms of cost only that all the four requirements mentioned above can be expressed. The measure of each which will enable air transport to

pay its way is not yet known with certainty, though experience is accumulating rapidly. Further information on this matter will be found in the article AVIATION, CIVIL. From the point of view of DESIGN, with which this article deals, *safety* is discussed below; within certain limits *comfort* can be had, as usual, if the traveller is prepared to pay for it; and *reliability* (in so far as it depends on design) presents no special problems.

In what follows we shall discuss (1) the *Minimum Speed of Flight* and its influence on the design of aeroplanes; (2) The

FIG. 1.—DIAGRAMS SHOWING HOW THE POWER REQUIRED VARIES WITH IN POUNDS PER SQUARE FOOT, LIFT COEFFICIENT AND SPEED

Power Required for Flight, including both that necessary to drive the aircraft through the air and also—the unique feature of transport by aircraft heavier-than-air—that expended in sustaining it in flight; (3) The possibilities of *Improvement of Performance* by reduction of resistance; (4) the *Origin of Aerodynamic data of Design*; (5) the *Distribution of Weight* among the component parts; (6) the *External Form of Aeroplanes*, commenting on the most conspicuous features of modern aircraft; (7) *Stability and Control* and their influence on (8) the *Safety of Air Travel*; concluding with notes on (9) *Structural Design* and (10) *Materials used in Construction*.

1. MINIMUM SPEED OF FLIGHT

It is the impossibility of steady flight *below* the stalling speed that constitutes the chief danger of air travel. Many attempts have been made to avoid this source of danger by devising an aeroplane which would be capable, as a whole, of remaining stationary in the air. Such machines have generally employed either flapping or rotating wings, the so-called ORNITHOPTERS and HELICOPTERS. The former have shared the legendary fate of Icarus. Of the latter there is at the moment only one example which offers a prospect of success, the de la Cierva Autogiro or GYROPLANE (*q.v.*).

There is no fundamental obstacle to reducing the minimum speed of a normal aeroplane to some 25 m.p.h., instead of the 40 to 65 m.p.h. quoted above as typical of modern practice. In fact the earliest flying machine had minimum speeds of this order. But the general proportions of such a machine would be uneconomical from every other point of view. In particular almost the whole of the available weight would be absorbed by the structure and power plant, leaving no margin for paying load.

The relation between the total weight (W lb.), the area of the wing (S sq. ft.) and the aerodynamic coefficient (k_L) which determines their lift at any given speed (V ft./sec.) (*see* AERODYNAMICS) is

$$W = k_L \rho S V^2,$$

ρ being the density of the air.

This may be put, for average ground level density, in the form

$$V = 14 \sqrt{\frac{w}{k_L}} \text{ miles per hour}$$

where $w = W/S$ and is called the wing loading, in pounds per square foot. Fig. 1 shows the possible combinations of w and k_L

which will give any selected speed. Fig. 2 shows the cross section by a vertical plane parallel to the direction of flight of some modern wing sections. For these the maximum value of k_L (which in virtue of the above relation corresponds to the minimum flying speed) is between 0.55 and 0.65, represented by the shaded band in fig. 1. Modern commercial aircraft using such wings have loadings between 9 and 14 lb. per square foot. A reduction in the stalling speed can be made only by reducing the wing loading or by using a shape of wing section which will give a higher maximum value of k_L . The former course leads to a reduction in the paying load. Much attention has therefore been devoted to the latter method.

The most effective of the high lift wing sections which have been devised as yet is the "slotted" wing of F. Handley Page (fig. 3). With this the maximum lift coefficient can be increased some 50% or more. The action of the device is, broadly speaking, to cause the flow characteristic of stalling (see AERODYNAMICS) to occur at a larger angle of incidence.¹ The increase in lift is dependent on the relative position of the main and auxiliary wings, i.e., on the size and shape of the slot between them, which can be varied in flight. With the slot closed the characteristics are nearly the same as those of a normal wing. In this respect form *a* (fig. 3) is superior to form *b*, but in practice there are, with both, constructional difficulties in the way of ensuring a smooth and unbroken surface when the slot is closed.

Another method which has been widely used, is to vary the curvature, or "camber," of the wing (fig. 4). In general, the greater the curvature of a wing section the higher is the maximum lift, but the lower the efficiency at high speeds. This device attempts to secure both high lift and high efficiency by enabling the pilot to alter the curvature to suit the conditions of flight. The increase of lift attainable in this way is much less than can be achieved with a slot, the maximum being about 10%. An automatic form of this device has also been used, the trailing flap being held down by elastic cord and therefore rising as the air pressure increases, i.e., as the speed increases. By combining both these methods very high maximum lifts have been obtained, and it is probable that such a combination will be used on civil aircraft in the near future.

The chief obstacles to the use of these variable wings in commercial aircraft are, first, the increase in weight involved, not only in the devices themselves, but also in the larger control surfaces which they require; second, the lack of a clear demand on the part of those who travel by air for a reduction in stalling speed. The increase in weight is not as great as the increase in lift (at the same speed), but the whole aeroplane is appreciably more costly, and in the absence of adequate credit for the benefits derived it is natural that designers should hesitate to adopt such devices. Further remarks on the application of the slotted wing to improve the control of aeroplanes will be found below (§7) and in the article AILERON.

2. POWER REQUIRED FOR FLIGHT

When an aeroplane of conventional design and normal proportions is flying horizontally (in air of a given density) the power of the engine is disposed of in the following ways:

¹Angle of the chord to the direction of flight. The chord of the wing sections in fig. 2 is indicated by a broken line.

(a) About 25% is lost owing to the inefficiency of the airscrew.

(b) From 30% to 45% is used in overcoming the resistance of the air to the passage of the body, including the engine itself, the undercarriage and the exposed part of the wing structure, etc.

(c) From 45% to 30% is similarly absorbed by the resistance of the wings.

The choice between the alternative figures in (b) and (c) depends on the speed of flight, the former corresponding to low, and the latter to high speeds. The resistance of the parts included in (a) varies practically as the square of the speed of flight, and

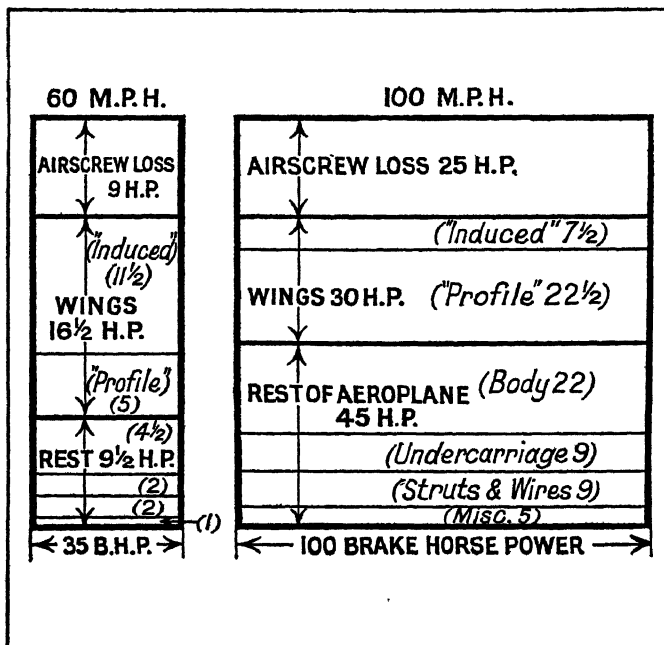

FIG. 5.—DIAGRAMS SHOWING HOW THE POWER REQUIRED VARIES WITH THE SPEED AND THE PROPORTIONS IN WHICH IT IS ABSORBED BY THE LOSS IN THE AIR SCREW AND BY THE RESISTANCE OF THE VARIOUS PARTS OF THE AEROPLANE

the corresponding power therefore as the cube. The resistance of the wings (c) may be further subdivided as follows:

(c. 1) From a third to three-quarters is due to the equivalent of friction of the air on the surface of the wings (the *profile* drag). This varies as the square of the speed, and the power as the cube. If the area of the wing is changed, the profile drag changes in proportion. Each wing section has a typical coefficient of profile drag, and, apart from maximum lift, this is in fact nearly all that distinguishes one section from another.

(c. 2) From two-thirds to a quarter is due directly to the action of the wings as generators of a lifting force (the *induced* drag of Prandtl; see AERODYNAMICS). This varies inversely as the square of the speed, and the power therefore inversely as the speed. It does not depend on the shape of the wing section, or on the area of the wings, but (for a given lifting force, i.e., weight) only on their overall width or span, being inversely proportional to the square of the span. This induced resistance is the essential feature in which transport by aircraft heavier than air differs from all other methods, for in no other is it necessary to expend energy in order to sustain the vehicle. About 8% of the fuel used by a normal aeroplane is used in this way (fig. 5).

This division of the resistance of the wings into two parts—one of which increases with the speed of flight, while the other decreases, the former dependent (broadly speaking) only on the section and shape of the wings, the latter independent of these factors and governed by the extent to which the span of the wings allows the aeroplane to "grip" the air (see AIRSCREW)—was originally suggested by F. W. Lanchester. It lay dormant for some years, largely because there was not forthcoming any adequate theory by means of which it would be given quantitative expression in terms of the dimensions of the wings. This expression has been rendered possible by the work of L. Prandtl of

Göttingen and his collaborators, with great advantage to the technique of aeroplane design. Its chief merit is that it enables a designer to examine the economics of wing proportions without continual resort to model experiments. It has been abundantly verified by comparison with experiments, both in Great Britain and elsewhere, and its applications have been extended by workers in Great Britain, in particular H. Glauert. The experiments made have not enabled its fundamental ideas to be verified directly, but have shown that it adequately accounts for very varied observations. Many engineering theories stand on a similar footing.

In normal flying conditions, as opposed to the special conditions characteristic of arising from and alighting on the ground, the speed of an aeroplane may vary from 1.2 to 2.0 times its stalling speed. The upper of these two figures can be raised by the provision of more power, that given corresponding to a machine having about 60b.h.p. for each 1,000 lb. of total weight, which is a normal figure for a commercial aeroplane. At its top speed the engine is working at its full power, which is not an economical condition from the point of view either of the life of the engine or of fuel consumed per ton-mile. The most economical speed, taking into consideration all the various factors, is about 1.5 times the minimum speed. The diagrams in fig. 5 show the way in which the power required for flight depends on the speed, and incorporate the figures given above relating to the distribution of the power among the various parts. The maximum brake horsepower of the engine has been taken to be 100 and the minimum speed 50m. per hour. These diagrams illustrate the rapid rise of power required with the speed of flight. For such an aeroplane the most economical speed would be about 75m.p.h., requiring about 50 brake horse-power.

If the engine throttle is fully opened at the lower of the two speeds considered above, the aeroplane will climb. The angle of climb for modern commercial aeroplanes is from 1 in 10 to 1 in 15. For high-powered war machines it may rise to 1 in 6, or more. When the engine is cut off the aeroplane will lose height, its path being inclined downwards at a corresponding angle, and the necessary power will be supplied by gravity. The angle of descent for a modern aeroplane is from 1 in 6 to 1 in 8. Thus a passenger in an aeroplane will not in general be subjected to greater changes of inclination of the direction of motion than one who travels by road.

3. IMPROVEMENT OF PERFORMANCE

The above proportions apply without material change to most modern commercial aeroplanes. The main directions in which improvements in the efficiency of the machines are being sought are as follow:

Aircrew Efficiency.—A loss of between a quarter and a third of the power of the engine in the transmission gear would hardly be tolerated in road or rail transport. Transport by water, however, is burdened by a loss identical in character and of similar amount. It arises from the fact that the propulsive force is obtained by driving a fluid backwards. (*See AIRSCREW.*)

Resistance of the Body.—The majority of aeroplanes have in the nose of the body either an air-cooled engine, or a water-cooled engine with a radiator. With this arrangement the resistance of the body cannot be separated from that which is incurred in cooling the engine. This latter is equivalent to a reduction in the power of the engine of from 15% to 25% at the cruising speed of a normal commercial aeroplane. At higher speeds the loss is greater.

It is natural to endeavour to recover some of this by placing as much as possible of the load carried (fuel, crew, passengers) behind the radiating surfaces. But a large part of the loss remains, because such parts as these could, at least in principle, be placed in a stream-line body of very low resistance. Such bodies would, however, be heavy, and the conventional tractor aeroplane is by no means a bad compromise, especially when an air-cooled engine is used.

When a very high speed is required, as for example in racing aeroplanes, the cooling resistance can be eliminated by using a

water-cooled engine in combination with a radiator whose cooling surface is part of the smooth surface of the wings. Such a radiator is heavy and is exposed to damage, reasons which prevented the development of the scheme during the World War. It has, however, been used in the Schneider Cup and Pulitzer Trophy races, and the high speeds reached have been largely due to the use of the equivalent of about one-third of the wing surface of a normal aeroplane as a radiator. But the consensus of the opinion of designers in Great Britain appears to be that it is as yet unsuitable for employment in commercial aeroplanes.

Resistance of the Undercarriage.—The undercarriage of an aeroplane has a high resistance, mainly due to the wheels. If the wheels could be withdrawn into the body in flight an appreciable gain would result. Mechanical difficulties are involved owing to their large bulk, but the problem is worthy of attention.

Resistance of the Bracing of the Wings.—There has been a tendency, more noticeable in American, Dutch, French and German than in British designs, to eliminate external wing bracing entirely. There is little doubt but that this results in a heavier structure and a relatively less economical aeroplane than one in which a less extreme construction is adopted—an example of a general principle of all engineering design that extremes are seldom economical. The matter is dealt with below (§§ 6 and 9). But it may be remarked that there has been apparent for some time a tendency to reduce the amount of exposed bracing, of all kinds, without entirely eliminating it.

4. ORIGIN OF AERODYNAMIC DATA OF DESIGN

The designer bases his calculations on data derived from four main sources:

(1) Theoretical investigations, such as the Lanchester-Prandtl theory of the action of wings. (2) Experiments on models in wind tunnels. (3) Experiments on full scale aeroplanes in flight. (4) Analysis of the measured performance of aeroplanes. References to the first of these divisions will be found in the article on AERODYNAMICS, where also the principles underlying experiments on models are dealt with.

Wind Tunnel.—The wind tunnel has played a great part in the development of aeronautics. Many manufacturing firms possess their own tunnels, used mainly for measurements of the resistance of aeroplane bodies, etc., with a view to improving performance. National wind tunnels exist in many countries, generally reserved in principle for research on problems of wide interest and application. In Great Britain such tunnels exist at the National Physical Laboratory and the Royal Aircraft establishment, and they form a part of the equipment of most university institutions where the scientific problems of aeronautics are investigated.

The main advantage of model experiments is the ease with which the experimenter can control the conditions. They enable suggestions for improvements to be developed to the stage at which a trial on the full scale is possible.

Full Scale Experiments.—Most of the leading aircraft-producing countries carry out full scale experiments. In Great Britain they are made at the Royal Aircraft establishment under the control of the director of scientific research at the Air Ministry. Owing to the expense involved, private firms can do little work of this kind, but there is active co-operation between them and the Air Ministry, with great benefit to aeronautics. The results of such work will be found in the technical reports of the Aeronautical Research Committee.

Analysis of Performance Tests.—The measurements of speed and climb which are made during the acceptance tests of all aeroplanes are a valuable source of information for the designer. Their analysis enables an overall comparison between various types to be made on a rational basis, but necessarily lacks something in precision. For each type differs from the others in many features, so that, for example, an observed difference in speed cannot safely be ascribed to any one peculiarity. But with suitable precautions reliable information can be obtained in a convenient form. It is found that the factors which have the greatest influence on the speed and climb of an aeroplane are the *horse-power*

per unit of total weight and the total weight carried per unit of wing surface. For further details of the method, and its limitations, references given should be consulted.

5. DISTRIBUTION OF WEIGHT

Figure 6 illustrates the relative proportions of the total weight taken up by the various sections into which it is convenient to divide the component parts. The figures apply to an average commercial aeroplane of moderate size. The distribution of weight varies little from one machine to another, even over a consider-

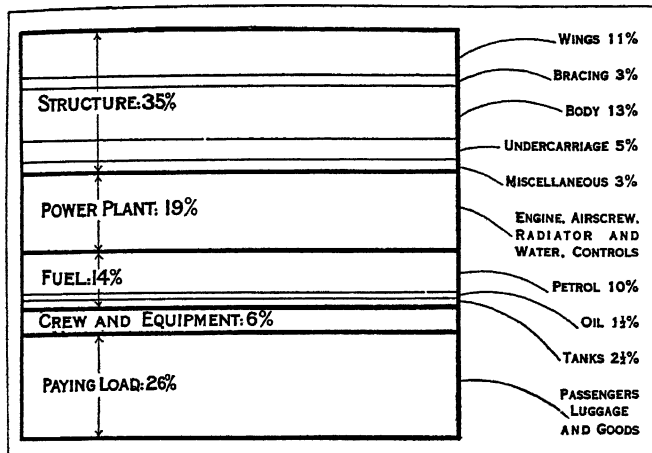

FIG. 6.—DISTRIBUTION OF TOTAL WEIGHT OF COMMERCIAL AEROPLANE

able range of size, provided the minimum speed, the cruising speed and the duration of flight are kept fixed.

Structure.—The "structure" includes a great deal which is not part of the essential structure of the aeroplane. A change in the specified strength affects about 60 to 70% only of the nominal structure weight.

Power Plant.—The weight of the power plant depends mainly on the desired maximum speed of the aeroplane, and on the weight of the engine and its equipment per brake horse-power. There is generally a reduction in this item if an air-cooled engine is used instead of a water-cooled engine.

Fuel, etc.—The weight of fuel and tanks is dependent on the speed and duration of flight specified, and on the standard of fuel economy reached by the engine. The latter factor varies little for modern engines, both air- and water-cooled engines now giving one brake horse-power hour for about $\frac{1}{2}$ lb. of petrol.

Crew, etc.—The crew and equipment tend naturally to absorb a progressively smaller proportion of the total weight as the size of the aeroplane increases.

Paying Load.—The paying load, being the balance after the above items have been accounted for, is from 20 to 30% of the gross loaded weight of the aeroplane. Compared with other means of transport this is a high proportion. For example, a modern motor-car of medium power, weighing some 2,500 lb. empty, will carry four passengers and a driver, equivalent to a paying load of some 650 lb. or 20% of the whole. Both a passenger railway train and an ocean liner carry a much smaller percentage of paying load. That all these means of transport are able to offer lower fares than aircraft is due partly to the high running costs of an aeroplane per passenger mile, but mainly to the fact that travellers are not yet convinced that air transport is safe.

The essential need for economy of weight in aircraft is due, not to the fact that only one-quarter of its weight is available for paying load, but to the high cost of carrying this load by air, as compared with other ways. A saving in the weight of some part of the aeroplane of 1% of the whole allows a reduction of the cost of transport by 4%.

6. EXTERNAL FORM OF AEROPLANES

Wings.—There is a striking lack of variation in the appearance as seen in plan of all modern aeroplanes. The main wings have

a large span (fig. 7a) in relation to their chord, the average ratio of span to chord being about seven. This is a direct consequence of the fact that the resistance due to the generation of lift varies inversely as the square of the span (§2). In some aeroplanes the chord diminishes towards the tip of each wing (fig. 7b) and occasionally the wings, although of uniform chord, are "swept back" (fig. 7c). Neither of these modifications affects the aerodynamic efficiency appreciably.

Near the tip of each wing is an *aileron* or wing flap hinged about axes 1-1 (fig. 7a) and interconnected so that an upward movement of one is accompanied by a downward movement of the other. They are operated by a sideways movement of the pilot's control column, and are the means by which the wings are kept level in straight flight, or banked for a turn, as may be required. (See also *AILERON*.)

Tail Plane.—At a distance of some three chords behind the leading edge of the wings is the tail plane, in area about one-ninth that of the wings. In steady flight its function is to balance or trim the aeroplane, *i.e.*, to ensure that the resultant of all the air forces on the aeroplane passes through the centre of gravity. (See *AERODYNAMICS*.) It is generally in two parts. The front part, some 60% of the whole, is normally fixed, though means are provided by which the pilot can alter its angle of incidence by rotating it about an axis such as 2-2 (fig. 7a), thus enabling the aeroplane to be trimmed for flying at various speeds. This operation is analogous to trimming the sails of a ship so that it carries no weather or lee helm. In a modern aeroplane a movable tail plane is generally considered indispensable.

The rear part of the tail, or *elevator*, is hinged on an axis such as 3-3 (fig. 7a), and connected to the control column in such a way that a forward movement of the pilot's hand depresses the trailing edge of the elevator and causes the machine to dive, and vice versa. The elevator is the primary control organ of an aeroplane, since by it the pilot alters the angle of incidence of the wings and hence controls the speed. (Fig. 9 of article *AERONAUTICS* shows control organs, and the forms which they take in more modern machines will be seen in the articles, *AERIAL NAVIGATION*; *AVIATION, CIVIL*.)

Number of Planes.—The appearance of aeroplanes in front and side elevation is more varied than that in plan, owing mainly to the use of one or more planes. As many as four planes have been used on comparatively modern aeroplanes, but the great majority of existing machines had in 1928 either one or two planes.

An analysis of the aeroplanes described in Jane's *All the World's Aircraft* for 1927 shows that, out of a total of nearly 600 types,

FIG. 7.—THE RELATIVE SIZES AND AREAS OF AEROPLANES, SHOWING THE SPAN OF THE MAIN WINGS IN RELATION TO THEIR CHORD, WHENCE THE AVERAGE RATIO OF SPAN TO CHORD MAY BE DEDUCED

31% were monoplanes and 69% biplanes, with no triplanes or quadraplanes. A similar analysis for 1922 gives, for rather more than one-third the number of aeroplanes, 22% monoplanes, 78% biplanes, with eight triplanes and one quadraplane. These figures show that the biplane is still the preponderating type, though the proportion of monoplanes is increasing. The increase during the five years covered is divided between biplanes and monoplanes in the ratio of 9 to 5 approximately. This trend is due partly to the development of wing sections of great depth in relation to their chord, and partly to a desire to eliminate external wing bracing.

It is more conspicuous in foreign than in British design, as will be seen from fig. 8, in which separate analyses are shown diagrammatically for aeroplanes produced in Great Britain, France, Germany, the United States and other countries. It should be noted that the figures given above refer to *types* and include both commercial and war aeroplanes and seaplanes. Some of these naturally exist only in small numbers, and some may be confined even to one experimental machine, but there is evidence that all have actually been made and flown. There is no room for doubt that had the above analyses dealt with numbers of aeroplanes, instead

FIG. 8.—SHOWING PERCENTAGE OF AEROPLANE TYPES PRODUCED IN 1922 AND 1927

of types, the preponderance of the biplane would have been much greater.

Confining attention to monoplanes and biplanes, the chief variations in front elevation are shown in fig. 9. The *parasol* monoplane (a) is used mainly where it is desired to have some of the advantages of external bracing. The monoplane with body above the wing (b) has rather less resistance and is less liable to damage by wind when on the ground, an important advantage. The former type is the more numerous, in the ratio of about 3 to 1, but the latter is favoured by the German firm of Junkers which has supplied a large proportion of the machines used on German air lines.

The biplane with wings of equal span (c) is the most common form of aeroplane, but wings of unequal span (d) (sometimes called *sesquiplane*, i.e., $1\frac{1}{2}$ plane) have many advantages. The proportion between types (c) and (d) is about 7 to 1. Fig. 9 (e) shows a large biplane with two or more engines. The right and left hand wings are generally not in line, but form a very flat upward Vee. This *dihedral angle* (which is generally given as the angle between either wing and the horizontal, and varies from 0° to 5°) is introduced in order to improve the lateral stability of the machine.

The corresponding side elevations of these aeroplanes are given in fig. 10. In a biplane the relative position of the planes as seen in this view varies as shown in (c), (d) and (e). In (c) and (d) the planes are *staggered*, i.e., the line joining the leading edge of the upper and lower planes is not perpendicular to their chords. The angle of stagger is generally between 0° and 30° and a variation over this range has little if any effect on the efficiency of the wings. In (d) the chord of the lower wing is smaller than that of the upper wing, a common variant, especially when the spans are also unequal (fig. 9). In (e) the wings have equal chords and no stagger. The tail plane is here shown as a biplane, in which form its weight can be made low for a considerable area.

Set of the Wings.—The angle at which the chord of the wings is set in relation to the centre line of the body is generally about five degrees. Though often termed the "angle of incidence," it has no connection with the accepted sense of that term (see § 1). Its magnitude is the result of a compromise between a number of conflicting requirements, a not unimportant one being the comfort of the passengers. The true angle of incidence being determined by the speed of flight, it is desirable that the relative position of

wings and body shall be such that in horizontal flight at cruising speed the body may be nearly horizontal. But the attitude of the body in relation to the wings has no effect whatever on their angle of incidence relative to the direction of flight. Failure to realize this has been responsible for many fruitless inventions of wings whose angular position on the body can be varied.

Fin and Rudder.—The vertical stabilizing and controlling surfaces, a fixed fin and a movable rudder connected to a rudder bar on which the pilot's feet rest, are situated near the tail plane. They perform practically the same function as the rudder of a boat and can be seen in more detail in fig. 9 of article AERONAUTICS.

Position of Airscrews and Engines.—In the three sketches the airscrews indicate the position of the engines. In modern aeroplanes the "pusher" position of the airscrew is seldom used except in single-engined flying boats, the vast majority of modern aeroplanes using tractor airscrews. When two or more engines are used, it is customary to distribute them along the wings, as the transmission of their power by means of shafts and gearing from a central engine-room to airscrews in suitable positions involves a prohibitive weight, generally not less than $1\frac{1}{2}$ lb. per h.p. transmitted, or about half the weight of the engine itself. As seen in front elevation the arrangements shown in fig. 11 have been used. Considerations of rudder control in the event of the failure of one engine make it desirable to place the engines as near to one another as the airscrews permit. Overlapping airscrews have been used, but have generally given rise to troublesome vibrations. It is also desirable that the axes of the airscrews should be, as far as possible, on the same horizontal level as the centre of gravity, in order to avoid giving rise to couples tending to make the aeroplane rotate in a vertical plane when the throttles are altered (see fig. 11).

7. STABILITY AND CONTROL

The general principles of stability and control are dealt with in the article AERODYNAMICS, and the stabilizing and controlling surfaces have been referred to above. The necessary disposition and dimensions of these surfaces are decided in practice chiefly by direct comparison with previous designs. Since, however, aeroplanes are not merely scale copies of one type, some rational means of using the accumulated experience of previous work is essential, and it is this that research into the fundamentals of stability and control is able to supply. Needless to say, even these methods break down when the aeroplane in question is not broadly similar to those from which the data are derived, and then nothing short of a thorough investigation, assisted by model experiments, will suffice. Very often, even with the best that can be done in this way, uncertainties remain, and the designer is

FIG. 9.—VARIATION IN THE FRONT ELEVATION OF MONOPLANES AND BIPLANES

forced, as in other branches of engineering design, to rely upon his ability to draw conclusions from insufficient premises.

Stability.—Stability, the property of returning to a steady state of motion when deliberately or accidentally disturbed, implies as a necessary preliminary the existence of equilibrium, or "trim," in that state. An aeroplane is trimmed for a steady condition of flight by an adjustment of its tail plane, the elevators being left free. The degree of stability generally considered desirable for a commercial aeroplane can be attained by arranging

the size of tail plane and the fore and aft position of the centre of gravity within certain limits. The further back the centre of gravity, the larger is the necessary tail area. The fore and aft position of the centre of gravity in relation to the wing is defined by its distance from a plane passing through the leading edge of the wing perpendicular to the chord, for a monoplane; for a biplane an equivalent monoplane wing is substituted. In normal aeroplanes this distance is usually about one-third the chord, though it has varied between one-quarter and one-half. The height of the centre of gravity of an aeroplane in relation to the wings has a secondary effect on its stability. In particular a low centre of gravity is not necessary for stability. With the centre

FIG. 10.—THE SIDE ELEVATIONS OF THE AEROPLANES IN FIG. 9

of gravity in the first-mentioned position, stability will be secured providing the product of the ratios

$$\frac{\text{area of tail plane and elevator}}{\text{area of wings}} \text{ and } \frac{\text{distance of tail plane from centre of gravity}}{\text{chord of wings}}$$

is greater than about 0.35. The latter ratio is usually about 3, and the former one-eighth.

The fore and aft control required can generally be obtained if the ratio $\frac{\text{area of elevator}}{\text{area of fixed tail plane}}$ is about two-thirds.

Lateral stability depends mainly on the provision of an adequate fin and dihedral angle. While desirable for the comfort of the pilot, lateral stability is of minor importance compared with lateral control.

Aileron Control.—Ailerons of an area between $\frac{1}{12}$ and $\frac{1}{8}$ of that of the wings are usually provided, and give adequate control at all normal flying speeds. At low speeds, however (more accurately, at angles of incidence of the wings in the neighbourhood of stalling), not only are normal ailerons ineffective, but they may actually become a source of danger, their use aggravating an inherent tendency of the stalled wings to force the aeroplane into a spiral dive or spin. (See AILERON.)

Rudder Control.—An effective rudder is as essential for safety at low speeds as effective ailerons. The efficiency of any given rudder depends on its being arranged so that the body does not shield it, but it is generally found that when the product of the ratios

$$\frac{\text{area of rudder and fin}}{\text{area of wings}}$$

and

$$\frac{\text{distance of rudder from centre of gravity}}{\text{semi-span of wings}}$$

is above $1/20$, a satisfactory control is obtained. The latter ratio is usually about 1, so that the former should not be less than one-twentieth. The area of the rudder is generally about $\frac{2}{3}$ that of the rudder and fin combined.

8. SAFETY OF AIR TRAVEL

The risks to which those who travel by air are exposed are probably the chief influence which hinders the development of air

transport. These risks are associated with the following causes: (1) physical failure of the pilot, (2) fire when in flight, (3) collision when in flight, (4) breakage of the structure, (5) forced landing. Dangers of the first four types are not peculiar to aircraft and the precautions they involve are common to transport by road, rail and sea. The measures adopted in air transport have practically eliminated them. It is mainly the dangers which may arise when an aeroplane is forced to land that loom large in the minds of those who might otherwise travel by air. While it cannot be said that these fears are unwarranted, yet in so far as the design of aircraft is involved the position is rapidly improving.

Forced Landings.—The need for a forced landing arises primarily from failure of the power plant, generally due to a defect developing in some minor part and not to a breakage in the engine itself. Deprived of its power an aeroplane must eventually descend. In practice, from the height at which most civil flying takes place (about 3,000ft.), about three minutes are available in which the pilot may choose a landing place. If the failure occurs before the aeroplane has reached its working height, the time and the corresponding area of ground in which this landing place is to be found are reduced in proportion. These considerations unfortunately result in the pilot having to execute somewhat sharp turns in order to place the aeroplane correctly, and it is during these that the controllability of the machine is most severely tested. The ultimate danger lies in the fact that the speed of horizontal travel at the moment of landing cannot possibly be less than the stalling speed. In practice with a typical commercial aeroplane it will be between 65 and 75 m. per hour. The pilot, therefore, endeavours to make the most of what space is available. This consideration, combined with the psychological effect of the apparent increase in the aeroplane's speed as the ground is approached,¹ lead him to carry out manoeuvres at a low speed, where the inherent characteristics of the aeroplane are least favourable and the controls least powerful (see above § 7).

The dangers associated with a forced landing may be reduced in three ways:

(1) The probability of complete failure of the power plant may be reduced by subdivision. Machines with three engines are coming into favour, capable of maintaining their height with any two engines and of greatly prolonging the time of descent with one engine only working. (2) The controls may be so arranged that they give the pilot complete command over the attitude of the aeroplane right down to the stalling speed. (3) The stalling speed

FIG. 11.—FRONT ELEVATIONS SHOWING ARRANGEMENTS OF ENGINES

may be reduced so that the space required for landing, and the consequent need for sharp turns, etc., are also reduced.

Reference has been made to what is now possible in the arrangement of controls. But even with controls as normally arranged, there is little room for doubt but that a limitation of the stalling speed of civil aircraft to some 50 m.p.h. would greatly reduce the principal danger of flying. A reduction in stalling speed reduces the space required for landing and therefore increases the proportion of the accessible ground which is suitable. It reduces the danger in the event of over-running the selected

¹To a passenger in an aeroplane 1,000 or 2,000ft. up, there is generally no sensation of speed relative to the ground.

landing ground, and it reduces the psychological effect on the pilot of the approach of the ground, in the opinion of some by no means the least valuable advantage. Such a limitation would probably involve for a time an increase in fares, since aeroplanes would be more costly. This might temporarily retard the development of flying, but in the end the gain in safety could react only to its advantage.

9. STRUCTURAL DESIGN

The General Problem.—The aeroplane shown in fig. 9, article AERONAUTICS, was designed about 1914; in general aerodynamic and structural design it is not fundamentally different from most modern aeroplanes. Regarded as a problem in structural design, a normal aeroplane wing, such as that illustrated, is a double cantilever, *i.e.*, two similar cantilevers joined at their roots, carrying a load distributed approximately uniformly over its span. The intensity of the loading begins to diminish appreciably at about one chord from the tip, but is still $\frac{2}{3}$ of its value at the centre, at a distance of $\frac{1}{2}$ chord from the tip. The wing itself is essentially a lamina, the wing sections most commonly used (*see* fig. 2) having a greatest depth of from $\frac{1}{4}$ to $\frac{1}{2}$ chord. The resultant loading is nearly perpendicular to the chord, but its line of action (as seen in side elevation) intersects the chord at a point (the so-called "centre of pressure") whose distance from the leading edge of the wing varies from $\frac{1}{3}$ to $\frac{1}{2}$ chord in normal flight, but may travel much further to the rear—even beyond the trailing edge—in special conditions. As a whole, therefore, the wing structure must be capable of taking torsion.

From general principles it would appear that the lightest way of bracing such a lamina would be to stiffen it internally by longitudinal and transverse beams (spars and ribs), and to support these by external bracing. The arrangement of two planes, one above the other, connected by struts and wires to form a braced tubular girder, suggested itself to the earliest experimenters in flight. Such a solution (*see* fig. 9 of AERONAUTICS) is typical of the majority of modern aeroplanes.

Alternatively, by tapering the wing in plan (fig. 7 *b*) and thus both reducing the intensity of loading outwards from the centre (though not, it appears, in proportion to the reduction of the chord), and increasing the available depth at the root, the whole of the necessary structure could be contained inside the covering. This is the principle of the internally braced wing characteristic of many foreign designers. It has the advantage of avoiding the resistance of the exposed bracing which is involved in the first solution.

Comparison of Monoplane and Biplane.—Many variants of these two main schemes have been used, but in general there is a clear division between them. The first undoubtedly produces a lighter structure and a more compact aeroplane. For, with the

FIG. 12.—COMPARISON OF PLAN VIEWS OF MONOPLANE AND BIPLANE OF SAME TOTAL WEIGHT AND PERFORMANCE

same total weight and wing area, the biplane has a smaller span and chord and requires a shorter body and smaller tail.

With the aid of the Prandtl theory it is possible to arrive at comparative overall dimensions for a normal biplane and a monoplane of otherwise similar characteristics. Such a comparison is shown in fig. 12. The span of the monoplane (full lines) is about 10% larger than that of the biplane (thin lines), and its chord 65% larger. Both the length of the body and the tail area required by the monoplane are greater by about 28%. Each type has

other advantages and disadvantages, but the mere existence of many examples of each indicates that technical opinion is divided on their merits, and experience in the design and manufacture of one or the other is a dominating factor in the choice between them. (*See* also BIPLANE and MONOPLANE.)

Refinement in Details.—The details of the structural design depend largely on the materials used (*see* below). But the main problems are not essentially different from those of the design of ordinary engineering structures, except in one particular. The importance of saving weight in every item of an aeroplane (§ 5) makes it economically possible to carry refinement in design to a point not usually attempted in any other structure. For the same reason elaborate calculations are made during the design, and the effect of every minor strengthening is carefully considered. All aeroplane structures are highly redundant and initial stresses are imposed on the members by tightening the bracing wires, in order to increase the stiffness of the structure. The design of modern aeroplane structure takes account of these features as far as it is possible to do so, in contrast to the general tendency of modern bridge design, for example, which tends to avoid them as sources of uncertainty (*see* BRIDGES). Where saving of weight is a prime consideration such a course is not possible.

Strength of Aeroplane Structures.—Since an aeroplane must be able to manoeuvre rapidly, many systems of air pressure, differing both in distribution and in intensity, must be taken into account. How rapidly it should manoeuvre depends on its class, *e.g.*, a small war machine must be able to execute safely any manoeuvre of which an aeroplane is capable, whereas less exacting conditions suffice for a large commercial machine. Spins, rolls, loops have all to be considered and experiments have been made in order to ascertain the distribution of the air pressure in such manoeuvres. The fundamental manoeuvre is, however, that of rapid recovery from a steep dive at a high speed, and here the combined effect of centrifugal force and gravity produces an "equivalent gravity" (*see* AERODYNAMICS) several times the normal. It can be shown that, given the necessary control power and indifference to his own safety, the pilot of an aeroplane could impose in this way forces up to 10 or 12 times those which the structure has to bear in the normal flight. As much as seven times normal gravity has been recorded in experiments under war conditions.

This number, the ratio between the effective and the normal value of gravity, is termed the *load factor* for the whole machine under the stated conditions. A normal commercial aeroplane need never experience a load factor of as much as two in flight. In practice it is designed to bear a factor of from four to six, dependent on its size and class. The ratio between the maximum load factor considered in the design, for any stated form of distribution of air pressure, and the factor in any actual condition of flight appropriate to that distribution, is the nearest approach to the *factor of safety* commonly used in engineering.

For a commercial aeroplane the factor of safety, as thus defined, seldom falls below three. In normal level flight it is of the order of five. For a war aeroplane it may fall to $1\frac{1}{2}$, so that the most highly stressed member is loaded to two-thirds of its breaking load, or even more, but only in extremely rapid manoeuvres.

A commercial aeroplane has a *true* factor of safety, a margin of strength not called upon under the worst conditions which it normally experiences. The load factors corresponding to irregularities in the air are very small. So long as it is in the air, an aeroplane is exposed to much smaller risk of the failure of its structure by stress of weather than is a ship at sea. Any commercial aeroplane which conforms to the official criterion of strength, and has thereby secured an air-worthiness certificate without which it may not carry passengers, is capable of performing many manoeuvres such as looping and spinning with complete safety.

10. MATERIALS USED IN CONSTRUCTION

Composite Structures.—The materials which have been most commonly used hitherto for the main structural members of aeroplanes are wood and steel, with a fabric covering for the

wings. The wood used is chiefly spruce of the highest grade, and in many aeroplanes the whole of the main structure, with the exception of ties and joints, is of this material. Ties and the joints or fittings by which they are attached to the other members are generally of steel. Steel tubes are used in some parts, either, as in the undercarriage, on account of their robustness, or, as in the control mechanism, because of their efficiency in transmitting torsion.

The arrangement of the members of a conventional aeroplane structure of this composite character will be seen in fig. 9 of AERONAUTICS. The cross section of the wing spars has the I section used in general structural engineering, though the thickness of the web and flanges is much larger in proportion to the overall dimensions of the section than is usual in steel I girders.

The wings of the aeroplane shown in fig. 9 are in biplane form with external bracing. Composite construction has also been applied to wings with no external bracing, generally, but not invariably, monoplanes. The Dutch firm of Fokker is the chief European exponent of such methods. Their wing structures are built mainly of wood, the spars being box girders. The covering of the wings is of three-ply wood, which also enters largely into the ribs and spars.

In aeroplane construction the primary requirement is lightness, and a modern composite aeroplane structure is on the whole nearly as light as one of any other type of construction so far developed, for the same strength. At present it is also cheaper. Nevertheless, in so far as it embodies wood it suffers from the following disadvantages:

(1) Wood of a suitable grade cannot be freely obtained. (2) When exposed to the atmosphere, particularly to large changes in temperature and humidity, wood deteriorates more rapidly than steel or other metals. (3) Wood is not a reliable material. Its external appearance is often misleading as an indication of its internal condition. (4) In aeroplane structures glue and wood-screws cannot be entirely avoided. Both are sources of weakness and uncertainty. (5) When a wooden structure is involved in an accident, many of its members break completely and splinter, and the structure disintegrates, whereas metal members often merely bend, and an all-metal structure generally preserves much of its original shape. The passengers in a wooden aeroplane are thus exposed to greater danger in case of an accident. (6) Wood has no inherent resistance to fire and cannot be rendered fire-resisting.

These disadvantages of wood have been the chief incentive to the development of all-metal construction for aeroplanes.

All-metal Structures.—The development of all-metal structures by British designers has been mainly confined to replacing each of the wooden members of the composite structure described above by a metal member, using either steel or duralumin. In such a structure the load to be borne by each member is of a fairly simple character and can be estimated fairly closely. Hence a comparison of the merits of a composite and an all-metal structure on these lines can be reduced to a comparison of typical members.

On the other hand European and American designers have used all-metal construction chiefly for monoplanes with no external bracing. The most prominent example is the German firm of Junkers. A wing of this kind cannot readily be considered in detail. In fact it is definitely regarded by its designer as a structural whole. Its structure is highly redundant in character and the corrugated metal covering combines the function of the ribs and fabric found in most other aeroplanes, and in addition contributes largely to the torsional stiffness of the whole wing, a function which in a biplane is performed mainly by the wire bracing. The relative advantages and disadvantages of these two distinct types of aeroplanes are concerned more with their general characteristics than with the materials of their structures (§§ 6 and 9).

Relative Cost of Wood and Metal.—The world's demand for aeroplanes is uneconomical in character. The total volume of the demand is small and it is spread over a large number of types. This reacts to the disadvantage of all-metal aeroplanes in particular. Wood is an economical material when small quan-

ties of many types of articles have to be manufactured. The same raw material is required, and it can readily be shaped to efficient sections by the same simple tools and equipment. With metal, the raw material must be prepared by special plant into the necessary forms (tubes, strip, wire, etc.) and these processes are economical only when large quantities of one form are required. But given the demand for a standard article, metal is cheaper than wood.

Many of the metal details of aeroplanes have been standardized since early in the War, and nearly all the raw materials are now the subject of specifications issued by the British Engineering Standards Association. But there is little as yet to correspond with the standard sizes of steel beams (I, angle, channel, etc.) which are essential to economy in general structural engineering, though design is now approaching the stage when such a step will be possible. Against the high first cost, however, must be offset the longer life and greater reliability of metal, and it cannot be doubted that wood as a material for the construction of aircraft is rapidly becoming obsolete.

Physical Properties of Materials.—The disadvantages of wood as a material for the structure of an aeroplane, outlined above, give an idea of what should be the characteristics of a satisfactory material. There is the usual difficulty, common to most problems of engineering design, of assessing the relative importance of each of these characteristics. In fact, their relative positions in the scale change with time and circumstances. But, owing to the low weight of the composite structures characteristic of modern aeroplanes, the technical problem is simplified into that of finding means of making, at the worst equally light, and preferably lighter structures from materials that do not share with wood the disadvantages mentioned. Table I. (p. 258) gives the strength and specific gravity of various materials which have been, or are likely to be, used for the main structural members of aircraft. They fall into three classes: wood, steel and light non-ferrous metals. The comparatively short life of wood has been quoted as one of its main disadvantages. Both steel and aluminium alloys need protection against corrosion (probably the most promising metal from this point of view is stainless steel). Although it would be misleading to suggest that all the problems of protection of metal structures have been solved, the experience gained suggests that effective protection can be given against all the ordinary causes of corrosion.

Struts and Beams of Thin Metal.—It is customary to regard the single figure obtained by dividing the strength by the specific gravity as a figure of merit on which the material can be judged. Such figures are not given in Table I. as they are not, in fact, a reliable criterion for all types of structural members.

The types of members responsible for the larger part of the weight of the structure of an aeroplane are two, struts and beams, the latter very often having to serve also as struts. Such members have essentially a *variation of stress* over their cross section, so that when the most heavily stressed point reaches the *limiting stress* of the material (this may be taken to mark the failure of the member as a whole), the majority of the material is under a lower stress. Hence the density of the material divided by its limiting stress is not in general proportional to the weight of the member.

In general, for a given area of cross section and a given limiting stress, the more the material can be spread out, *e.g.*, in the form of a circle, the greater will be the strength of the strut or beam, but the thinner will the material become. It appears, however, that a limit is reached for steel when the thickness is about $\frac{1}{30}$ the radius, beyond which an increase in the radius causes a decrease in strength. The member will then fail owing to local buckling of the material, at a load which corresponds to a maximum stress in the material, as calculated in the conventional way, which is below the limiting stress. The design of metal structures for aircraft hinges round the discovery of shapes of cross section which will enable the limiting stress of the material to be reached, and will be convenient for manufacture. The members must also be robust enough to ensure that ordinary handling does not damage them, a serious problem with thin sheets or tubes,

FIG. 13—EXAMPLES OF METAL CONSTRUCTION OF SPARS AND RIBS FOR AEROPLANE WINGS

- A. Section of corrugated steel spar, showing method of attaching rib by means of spring steel clips riveted to struts, pressing into corrugations in the spar
 B. Inner end of wing in steel, showing wide rib and attachment of wing to aeroplane

- C. Corrugated steel spar using transverse tubes to stiffen webs, and duralumin strips to stiffen flanges
 D. Internal construction of wing in duralumin. Spar built up from sheet and angles. Ribs made from tube and channels
 E. Simplified wing spar in duralumin. The greatest depth of each of the spars is about 5 inches

Limiting Stress.—The limiting stress in question is probably what is termed the yield point in compression, the stress at which plastic strain begins, for materials such as mild steel. For high tensile steel and light alloys (in practice the aluminium alloy known as *duralumin* is the one most used), there is no definite yield point and the limiting stress is accordingly somewhat uncertain. Shapes for members (*see* fig. 13) have been devised in which the greatest stress at failure is some 60 to 70% of the ultimate tensile strength of the materials (*see* Table I., column

under compressive stresses. Corrugation, in any direction which does not make too great an angle with the direction of the stress, stiffens it against such buckling. Moreover, it greatly reduces the influence of the inevitable local irregularities in actual materials, and gives robustness to what would otherwise be a very easily damaged member. It has been found essential in struts and beams of thin metal, to corrugate *longitudinally*. Transverse corrugations have proved ineffective.

Steel strip of thickness as low as $\frac{1}{100}$ in. has been used in aeroplane spars and ribs. The material is either cold-rolled medium carbon steel, whose essential properties have been improved by a process known as blueing (heating to some $350^{\circ}\text{C}.$), but is otherwise not heat treated, or a nickel chromium alloy steel, hardened and tempered. Hitherto the strip has been formed into the final shape cold and without any subsequent treatment. This restricts the sections which can be produced and the materials which can be used owing to the need for ductility in order to avoid cracks. Progress has been made in the direction of forming the shapes while the material is in an annealed state and heat treating subsequently. This method will probably supersede "hard" drawing and rolling.

For spars of the size shown in fig. 13, it has been found that the low specific gravity of duralumin makes it possible to use material of such a thickness that corrugation is not always necessary. The resulting shapes resemble those used in bridge construction, though the lattice girder seen in fig. 13 *d* is found in practice to be heavier than the simpler shape in *e*. It is probable that, for the size of spar required in the largest present-day aeroplanes of the type under discussion, it is more economical of weight to use a spar composed of a few parts (such as *a*, *c* and *e*) than to build it up from many pieces. On the other hand for larger beams, such as are used in airships, a lattice construction is lighter. Probably the lightest all-metal construction for a wing structure using spars and ribs, etc., combines both steel and duralumin, the former for the main members (spars and struts) and the latter for the subsidiary ribs and edges. With the methods outlined above it is now possible to make an all-metal aeroplane certainly as light as, and sometimes lighter than, the corresponding composite machine.

TABLE I.

Material.	Specific gravity.	Ultimate Tensile Strength (tons/sq. in.)	Effective strength in compression (tons/sq. in.)
<i>Wood</i> —			
Spruce	0.45	about 3	2
<i>Steel</i> —			
Mild (soft)	7.8	26	15
Plain carbon steel bar for ties (cold-rolled)	7.8	70	..
Plain carbon steel strip (cold-rolled and blueed)	7.8	60	50
$3\frac{1}{2}\%$ nickel steel strip (hardened and tempered)	7.8	90	60
<i>Light metals</i> —			
Aluminium (cold-rolled)	2.6	10	8
Duralumin	2.85	27	17

headed "Effective Strength in Compression"), and there is reason to suppose that this is not far from the best that can be achieved. Some improvement may be anticipated from an extension of these results to still higher grades of steel, or from the development of a light alloy stronger than duralumin, but at the present time attention is concentrated mainly on the improvement of manufacturing methods.

The ruling principle in the shapes of cross section which have achieved these results with steel is *corrugation* of the thin sheet material used. The theory of the collapse of corrugated material awaits development, design being at present largely empirical. But the general nature of the strengthening effect of corrugation is well understood. A flat sheet of thin metal buckles readily

AEROTHERAPEUTICS. In addition to the general use of open air and sunshine, there are several particular ways of using air for therapeutic purposes. Thus oxygen enriched air is used for those made ill through breathing irritant gases such as were used in warfare. These gases evoke oedema of the lungs and danger of suffocation through want of oxygen. So, too, in cases of pneumonia, shock and failing circulation, oxygen inhalation is useful. It is administered either by a mask or in a special chamber in which the patient is put. In the latter case great precaution must be taken against the danger of fire.

Oxygen containing 5% of carbon dioxide provokes deep breathing, and is useful in cases when the lungs require expanding, as after operations for empyema, when hypostatic congestion of the lungs threatens, and in cases of poisoning by carbon monoxide, as in ordinary coal-gas poisoning, etc. This mixture is particularly useful for breathing during induction of and after anaesthesia with ether, since the deep respiration induces anaesthesia quickly, and washes the ether out of the body at the end of the anaesthetic period. The breathing of nitrous oxide and oxygen in a compressed air chamber at half an atmosphere extra pressure gives deep and safe anaesthesia.

Certain dusts in the air act as irritants to those affected with hay fever and asthma, e.g., the pollen of plants, spores of aspergillus mould. It has been found possible to relieve such patients by sending them to the high Alps.

In a mercurial or sulphur bath, the patient, enveloped in a sheet, sits on a chair beneath which a lamp is placed both to volatilize the drug and produce a steamy atmosphere. The vapour is absorbed by the skin. This treatment is used for syphilis and also for scabies and other affections of the skin. (See THERAPEUTICS.)

Air at a low pressure is used locally for cupping and thus producing local congestion, the blood being drawn into the part to which the cupping apparatus is applied at the expense of other organs. A similar result is got by local application of heat, poultices, etc. In operations where the chest cavity is opened air is blown into the lungs through a tube introduced through the larynx in order to keep the lungs distended.

Ozonized Air.—Ozonized air has been used in treatment of phthisis and wounds. Ozone is an irritant to the lungs and can be used safely only in very weak concentrations, e.g., in a concentration just perceptible to the smell. It takes away the power to smell bad odours, but otherwise has no valuable properties which have been proven. Its chief use, then, is for deodorizing offensive smells. (L. E. H.)

AERSCHOT, PHILIPPE DE CROY, DUKE OF (1526-1595), prince of Chimay, governor-general of Flanders, was born at Valenciennes, and inherited the estates of the ancient and wealthy family of Croy. He was appointed governor of the citadel of Antwerp when the Spanish troops withdrew in 1577. After a period of vacillation he deserted Don John towards the end of that year. Jealous of the prince of Orange, he was then the head of the party which induced the archduke Matthias (afterwards emperor) to undertake the sovereignty of the Netherlands, and soon afterwards was appointed governor of Flanders by the state council. A strong party, including the burghers of Ghent, distrusted the new governor; and Aerschot, who was taken prisoner during a riot at Ghent, was only released on promising to resign his office. He then sought to regain the favour of Philip of Spain, and having been pardoned by the king in 1580 shared in the government of the Netherlands; but he refused to serve under the count of Fuentes when he became governor-general in 1594, and retired to Venice, where he died on Dec. 11, 1595.

See J. L. Motley, *The Rise of the Dutch Republic*.

AERTSZEN (or AARTSEN), PIETER (1507-1573), called "long Peter" on account of his height, Dutch historical painter, was born and died at Amsterdam. When a youth he distinguished himself by painting homely scenes, in which he reproduced articles of furniture, cooking utensils, etc., with marvellous fidelity. An excellent specimen of his style on a small scale, a picture of the Crucifixion, may be seen in the Antwerp Museum. Aertszen was a member of the Academy of St. Luke, in the books of which he is entered as *Langhe Peter, schilder*. Three of his sons attained to some note as painters.

AESCHINES (5th century B.C.), an Athenian philosopher and orator and a friend of Socrates. Diogenes Laertius preserves a tradition that it was he, not Crito, who offered to help Socrates to escape from prison. He was always a poor man. He started a perfumery shop in Athens on borrowed capital, became bankrupt and retired to the Syracusan court. According to Diog. Laert. (ii. 61), Plato, then at Syracuse, pointedly ignored Aeschines, but this does not agree with Plutarch *De adulatore et amico* (c. 26). On the expulsion of the younger Dionysius, Aeschines returned to Athens, and, finding it impossible to profess philosophy publicly owing to the contempt of Plato and Aristotle, was compelled to teach privately. Besides forensic speeches, noted for their purity of style, he wrote several philosophical dialogues: (1) *Concerning virtue, whether it can be taught*; (2) *Eryxias, or Erastistratus: concerning riches, whether they are good*; (3) *Axiochus: concerning death, whether it is to be feared*,—but those extant are not genuine remains.

J. le Clerc has given a Latin translation of them, with notes and several dissertations, entitled *Silvae Philologicae*, and they have been edited by S. N. Fischer (Leipzig, 1786), and K. F. Hermann *De Aeschin. Socrat. relig.* (Gött. 1850). An amusing passage of a genuine dialogue is quoted by Cicero in the *De inventione* (i. 31). Hirzel *Der Dialog*, i. 129-140; T. Gomperz *Greek Thinkers*, vol. iii. p. 342 (Eng. trans. G. G. Berry, London, 1905).

AESCHINES (389-314 B.C.) Athenian orator, the political opponent of Demosthenes. Aeschines and Demosthenes were both members of the first embassy to Philip (Feb.-March 346 B.C.). Philip's envoys appeared in the Assembly on April 15 and 16, and between these two meetings Aeschines appears to have been won over to Philip's interest; on the 15th he refused, with Demosthenes, to accept a clause excluding Phocis; on the 16th he supported a peace in which the question was left vague. The same ambassadors went to administer the oaths to Philip, but, after so delaying on their journey that Philip had time to make conquests in Thrace, Philocrates and Aeschines (out-voting Demosthenes), allowed him to exclude the Phocians. But on his return Aeschines falsely assured the Assembly that he had private information that Philip meant to support Phocis. The Athenians believed him and Phocis, left without support, surrendered.

In 345, Demosthenes accused Aeschines of misconduct, but Aeschines saved himself by an attack on Demosthenes' supporter (*in Timarchum*). In 343, Demosthenes renewed the attack, and Aeschines secured a bare acquittal (*De Falsa Legatione*).

In 340, war broke out again with Philip, and thanks to Aeschines, who stirred up a Sacred War in 339, he managed to enter Greece unopposed, as general of the Amphictyonic forces. Athens and Thebes, united by Demosthenes, resisted desperately, but were decisively defeated at Chaeroneia (338).

Aeschines' party secured favourable terms from Philip, and prosecuted Demosthenes on various charges, but the Athenians loyally supported him, and in 337 it was proposed to crown him for public services. Aeschines brought a *graphē paranomōn* against the proposer (*in Ctesiphontem*), but the case was not tried till 330. Demosthenes' speech on the Crown (a vindication of his whole policy) secured the condemnation of Aeschines, who withdrew to Rhodes.

AESCHYLUS (525-456 B.C.), Greek poet, the first of the only three Attic tragedians of whose work entire plays survive, and in a very real sense the founder of the Greek drama, was born at Eleusis in 525 B.C. His father, Euphorion, belonged to the "Eupatridae" or old nobility of Athens, as we know on the authority of the short *Life* of the poet given in the Medicean Manuscript (see note on "Authorities" at the end). According to the same tradition he took part as a soldier in the great struggle of Greece against Persia; and was present at the battles of Marathon, Artemisium, Salamis and Plataea, in the years 490-479. At least one of his brothers, Cynaegirus, fought with him at Marathon, and was killed in attempting a conspicuous act of bravery; and the brothers' portraits found a place in the national picture of the battle which the Athenians set up as a memorial in the Stoa Poecile (or "Pictured Porch") at Athens.

AESCHYLUS, FATHER OF THE GREEK DRAMA
Head now in the Capitoline Museum, Rome, believed to be that of Aeschylus, probably of about the 5th century, B.C.

The vigour and loftiness of tone which mark Aeschylus' poetic work were partly inspired by the personal share he took in the great actions of a heroic national uprising. In the same way, the poet's brooding thoughtfulness on deep questions—the power of the gods, their dealings with man, the dark mysteries of fate, the future life in Hades—though largely due to his turn of mind and temperament, was doubtless connected with the place where his childhood was passed. Eleusis was the centre of the most famous worship of Demeter which was intimately connected with the Greek beliefs about the human soul and the underworld.

His dramatic career began in 499 B.C. when he first exhibited at Athens; and his last work, the trilogy of the *Oresteia*, was exhibited in 458. The total number of his plays is stated by Suidas to have been 90; and the seven extant plays, with the dramas named or nameable which survive only in fragments, amount to over 80, so that Suidas' figure is probably based on reliable tradition. In the 5th century each exhibitor at the tragic contests produced four plays; and Aeschylus must therefore have competed (between 499 and 458) more than 20 times. His first victory is recorded in 484, 15 years after his earliest appearance on the stage; but in the remaining 26 years of his dramatic activity at Athens he was successful at least 12 times. Perhaps the most striking evidence of his exceptional position among his contemporaries is the well-known decree passed shortly after his death that whosoever desired to exhibit a play of Aeschylus should "receive a chorus," i.e., be officially allowed to produce the drama at the Dionysia. The existence of this decree, mentioned in the *Life*, is strongly confirmed by two passages in Aristophanes: first in the prologue of the *Acharnians* (acted in 425), where the citizen relates his great disappointment, when he took his seat in the theatre "expecting Aeschylus," to find that when the play came on it was Theognis; and secondly in a scene of the *Frogs* (acted 405 B.C.), where the throne of poetry is contested in Hades between Aeschylus and Euripides, the former complains (*Fr.* 866) that "the battle is not fair, because my own poetry has not died with me, while Euripides' has died, and therefore *he will have it with him to recite*"—a clear reference, as the scholiast points out, to the continued production at Athens of Aeschylus' plays after his death.

The only other incidents recorded of the poet's life that deserve mention are connected with his Sicilian visits, and the charge preferred against him of revealing the "secrets of Demeter." This tale is mentioned by Aristotle (*Eth.* iii. 2), and Eustratius (12th century) quotes from one Heracleides Pontius the following version:

The poet was acting in one of his own plays, where there was a reference to Demeter. The audience suspected him of revealing the inviolable secrets, and rose in fury; the poet fled to the altar of Dionysus in the orchestra and so saved his life for the moment. He was afterwards charged with the crime before the Areopagus; and his plea "that he did not know that what he said was secret" secured his acquittal. The commentator adds that the prowess of the poet (and his brother) at Marathon was the real cause of the leniency of his judges. In the above shape the story dates back to the 4th century; and as the main fact seems accepted by Aristotle, it is probably authentic.

As to his foreign travel, the suggestion has been made that certain descriptions in the *Persae*, and the fact that he wrote a trilogy on the story of the Thracian king, Lycurgus, seems to point to his having visited Thrace. This, however, remains at best a conjecture. For his repeated visits to Sicily, on the other hand, there is conclusive ancient evidence. Hieron the First, tyrant of Syracuse (478-467), who invited to his court famous poets and men of letters, had founded a new town, Aetna, on the site of Catana. About 476 Aeschylus was entertained by him, and at his request wrote and exhibited a play called *The Women of Aetna* in honour of the new town. He paid a second visit about 472, the year in which he had produced the *Persae* at Athens; and the play is said to have been repeated at Syracuse at his patron's request. Hieron died in 467, the year of the *Seven against Thebes*; but after 458, when the *Oresteia* was exhibited at Athens, we find the poet again in Sicily for the last time. In 456 he died, and was buried at Gela; and on his tomb was placed an epitaph in two elegiac couplets saying: "Beneath this stone lies Aeschylus, son of Euphorion, the Athenian, who perished in the wheat-bearing land of Gela; of his noble prowess the grove of Marathon can speak, or the long-haired Persian who knows it well." The *Life* says this epitaph was inscribed on his grave by the people of Gela, while Athenaeus and Pausanias attribute it to Aeschylus. Probably most people would agree that only the poet himself could have praised the soldier and kept silence about the poetry.

Of the marvellous traditions which gathered round his name little need be said. Pausanias' tale, how Dionysus appeared to the poet when a boy and bade him write a tragedy—or the account in the *Life*, how he was killed by an eagle letting fall on his head a tortoise—clearly belong to the same class of legends as the story that Plato was son of Apollo. Less supernatural, but hardly more historical, is the statement in the *Life* that the poet left Athens for Sicily in consequence of his defeat in the dramatic contest of 468 by Sophocles; or alternatively because Simonides' elegy on the heroes slain at Marathon was preferred to his own. Neither story fits the facts; for in 467, the next year after Sophocles' success, we know that Aeschylus won the prize of tragedy with the *Septem*; and the Marathon elegy must have been written in 490 about 14 years before his first visit to Sicily.

Aeschylus' Plays.—In passing from Aeschylus' life to his work, we have obviously far more trustworthy data, in the seven extant plays (with the fragments of more than 70 others), and particularly in the invaluable help of Aristotle's *Poetics*. The real importance of our poet in the development of the drama (see **DRAMA: Greek**) as compared with his predecessors is shown by the fact that Aristotle, in his brief review of the rise of tragedy (*Poet.* iv. 13), names no one before Aeschylus.

Tragedy grew out of the old choric song to Dionysus, to which was added first a spoken interlude by the chorus-leader, and later one actor (at first the poet), whom the mask enabled to appear in more than one part. But everything points to the fact that in the development of the drama Aeschylus was the decisive innovator. The two things that were important, when the 5th century began, if tragedy was to realize its possibilities, were (1) the disentanglement of the dialogue from its position as an interlude in an artistic and religious pageant that was primarily lyric; and (2) its general elevation of tone. Aeschylus, as we know on the express authority of Aristotle (*Poet.* iv. 13), achieved the first by the introduction of the second actor; and though he did not begin the second he gave to it the decisive impulse and consum-

mation by the overwhelming effect of his serious thought, the stately splendour of his style, his high dramatic purpose, and the artistic grandeur and impressiveness of the construction and presentment of his tragedies.

As to the importance of the second actor no argument is needed. The interacting personal influences of different characters on each other are indispensable to anything that can be called a play, as we understand the word; and, without two "personae dramatis" at the least, the drama in the strict sense is clearly impossible. The number of actors was afterwards increased; but to Aeschylus is due the essential step; and therefore, as was said above, he deserves, in a very real sense, to be called the founder of Athenian tragedy.

Of the seven extant plays, *Supplices*, *Persae*, *Septem contra Thebas*, *Prometheus*, *Agamemnon*, *Choephoroe* and *Eumenides*, five can be dated with certainty, as the archon's name is preserved in the Arguments; and the other two approximately. The dates rest, in the last resort, on the *didaskalia*, or the official records of the contests, of which Aristotle (and others) compiled catalogues; and some actual fragments have been recovered. The order of the plays is probably that given above; and certainly the *Persae* was acted in 472, *Septem* in 467, and the trilogy in 458. The *Supplices* is generally regarded as the oldest; and the best authorities tend to place it not far from 490. The early date is strongly confirmed by three things: the extreme simplicity of the plot, the choric (instead of dramatic) opening, and the fact that the percentage of lyric passages is 54, or the highest of all the seven plays. The chief doubt is in regard to *Prometheus*, but the very low percentage of lyrics (only 27, or roughly a quarter of the whole), and still more the strong characterization, a marked advance on anything in the first three plays, point to its being later than any except the trilogy, and suggest a date somewhere about 460, or perhaps a little earlier. A few comments on the extant plays will help to indicate the main points of Aeschylus' work.

Supplices.—The exceptional interest of the *Supplices* is due to its date. Being nearly 20 years earlier than any other extant play, it furnishes evidence of a stage in the evolution of Attic drama which would otherwise have been unrepresented. It probably resembles in general structure the lost works of Choerilus, Phrynichus, Pratinas and the 6th century pioneers of drama.

The plot is briefly as follows: the 50 daughters of Danaus (who are the chorus), betrothed by Aegyptus (their father's brother) to his 50 sons, flee with Danaus to Argos, to escape the marriage. They claim the protection of the Argive king, Pelasgus; and he (by a pleasing anachronism) refers the matter to the people, who agree to protect the fugitives. The pursuing fleet of suitors is seen approaching; the herald arrives, orders off the cowering Danaids to the ships and finally attempts to drag them away. Pelasgus interposes with a force, drives off the Egyptians and saves the suppliants. Danaus urges them to prayer, and the grateful chorus pass away to the shelter offered by their protectors.

It is clear that we have here the drama just developing out of the lyric pageant. The interest still centres round the chorus. Character and plot—the two essentials of drama—are both here rudimentary. The play is a single situation. It should not be forgotten, indeed, that the play is one of a trilogy—an act, therefore, rather than a complete drama. But we have only to compare it with those later plays of which the same is true, to see the difference. Even in a trilogy, each play is a complete whole in itself, though also a portion of a larger whole.

Persae.—The next play that has survived is the *Persae*, the only extant Greek historical drama. The plot is still severely simple, though more developed than that of the *Supplices*. The opening is still lyric, and the first quarter of the play brings out, by song and speech, the anxiety of the people and queen as to the fate of Xerxes' huge army. Then comes the messenger with the news of Salamis, including a description of the sea-fight itself which can only be called magnificent. The play is not a tragedy in the true Greek sense; its real aim is not the "pity and terror" of the developed drama; it is the triumphant

glorification of Athens, the exultation of the whole nation gathered in one place, over the ruin of their foe; and one effective incident is the raising of Darius's ghost, and his prophecy of the disastrous battle of Plataea. But in the ghost's revelations there is a mixture of audacity and naïveté, characteristic at once of the poet and the early youth of the drama.

Septem Contra Thebas.—Five years later came the Theban tragedy, which is (like the *Supplices*) one of a connected series, dealing with the evil fate of the Theban house, and traces the fate through three generations, Laius, Oedipus and the two sons who die by each other's hands in the fight for the Theban sovereignty. This family fate, where one evil deed leads to another after many years, is a larger conception, strikingly suited to Aeschylus' genius, and constitutes a notable stage in the development of the Aeschylean drama. In the last extant work, the *Oresteia*, the poet traces the tragedy of the Pelopid family, from Agamemnon's first sin to Orestes' vengeance and purification. And the names of several lost plays point to similar handling of the tragic trilogy.

The *Seven against Thebes* is the last play of its series; and again the plot is severely simple. Father and grandfather have both perished miserably; and the two princes both claim the kingdom. Eteocles has driven out Polyneices, who fled to Argos, gathered a host under seven leaders (himself being one), and when the play opens has begun the siege of his own city. The king appears, warns the people, chides the clamour of women, appoints seven Thebans, including himself, to defend the seven gates, departs to his post, meets his brother in battle and both are killed. The other chieftains are all slain, and the enemy beaten off. The two dead princes are buried by their two sisters, who alone are left of the royal house.

Various signs of the early drama are here manifest. Half the play is lyric; there is no complication of plot; the whole action is recited by messengers; and the predicted mutual slaughter of the princes is brought about by no accidental stroke of destiny, but by the choice of the king, Eteocles himself. On the other hand, the opening is no longer lyric (like the two earlier plays) but dramatic; the main scene, where the king appoints the seven defenders, must have been an impressive spectacle. One novelty should not be overlooked. There is here the first passage of *dianoia*, or general reflection of life, which later became a regular feature of tragedy. Eteocles muses on the fate which involves an innocent man in the company of the wicked so that he shares unjustly their deserved fate (*Theb.* 597–608). The whole part of Eteocles shows a new effort of the poet to draw character, which may have something to do with the rise of Sophocles, who in the year before (468) won the prize of tragedy. There remain only the *Prometheus* and the *Oresteia*, which show such marked advance that (it may almost be said) when we think of Aeschylus it is these four plays we have in mind.

Prometheus.—The Prometheus-trilogy consisted of three plays: *Prometheus the Fire-bringer*, *Prometheus Bound*, *Prometheus Unbound*. The two last necessarily came in that order; the *Fire-bringer* is probably the first of the trilogy. That Prometheus sinned against Zeus, by stealing fire from heaven; that he was punished by fearful tortures for ages; that he was finally reconciled to Zeus and set free—all this was the ancient tale indisputably. Those who hold the *Fire-bringer* (Πυρρόφορος) to be the final play, conjecture that it dealt with the establishment of the worship of Prometheus under that title, which is known to have existed at Athens. But the other order is on all grounds more probable; it keeps the natural sequence—crime, punishment, reconciliation, which is also the sequence in the *Oresteia*. And if the reconciliation was achieved in the second play, no scheme of action sufficing for the third drama seems even plausible.¹

The play that survives is a poem of unsurpassed force and impressiveness. Nevertheless, from the point of view of the

¹The *Eumenides* is quoted as a parallel, because there the establishment of this worship at Athens concludes the whole trilogy; but it is forgotten that in *Eumenides* there is much besides—the pursuit of Orestes, the refuge at Athens, the trial, the acquittal, the conciliation by Athena of the Furies; while here the story would be finished before the last play began.

development of drama, there seems at first sight little scope in the story for the normal human interest of a tragedy, since the actors are all divine, except Io; and between the opening where Prometheus is nailed to the Scythian rock, and the close where the earthquake engulfs the rock, the hero and the chorus, action in the ordinary sense is *ipso facto* impossible. This is just the opportunity for the poet's bold inventiveness and fine imagination.

Oceanus, the well-meaning palaverer old mentor, and Hermes, the blustering and futile jack-in-office, gods though they be, are vigorous, audacious and very human character-sketches; the soft entrance of the consoling nymphs is unspeakably beautiful; and the prophecy of Io's wanderings is a striking example of that new keen interest in the world outside which was felt by the Greeks of the 5th century, as it was felt by the Elizabethan English in a very similar epoch of national spirit and enterprise 2,000 years later. Thus, though dramatic action is by the nature of the case impossible for the hero, the visitors provide real drama.

Another important point in the development of tragedy is what we may call the "balanced issue." The hero is both a victim and a rebel. He is punished for his benefits to man; but though Zeus is tyrannous, the hero's reckless defiance is shocking to Greek feeling. As the play goes on, this is subtly indicated by the attitude of the chorus. They enter overflowing with pity. They are slowly alienated by the hero's impiety; but they decline, at the last crisis, the mean advice of Hermes to desert Prometheus; and in the final crash they share his fate.

Oresteia.—The last and greatest work of Aeschylus is the *Oresteia*, which also has the interest of being the only complete trilogy preserved to us. As in *Prometheus*, the plot, at first sight, is such that the conditions of drama seem to exclude much development in character-drawing. The gods are everywhere at the root of the action. The inspired prophet, Calchas, has demanded the sacrifice of the king's daughter, Iphigeneia, to appease the offended Artemis. The inspired Cassandra, brought in as a spear-won slave from conquered Troy, reveals the murderous past of the Pelopid house, and the imminent slaughter of the king by his wife. Apollo orders the son, Orestes, to avenge his father by killing the murderess, and protects him when after the deed he takes sanctuary at Delphi. The Erinyes ("Furies") pursue him over land and sea; and at last Athena gives him shelter at Athens, summons an Athenian council to judge his guilt, and when the court is equally divided gives her casting vote for mercy. The last act ends with the reconciliation of Athena and the Furies; and the latter receive a shrine and worship at Athens, and promise favour and prosperity to the great city. The scope for human drama seems deliberately restricted by such a story so handled. Nevertheless, the growth of characterization is not only visible but remarkable. Clytaemestra is one of the most powerfully presented characters of the Greek drama. And there is one other noticeable point. In this trilogy, Aeschylus, for the first time, has attempted some touches of character in two of the humbler parts, the watchman in *Agamemnon*, and the nurse in the *Choephoroe*. These two are veritable figures drawn from contemporary life; and though both appear only once, the innovation is most significant, and especially as adopted by Aeschylus.

Aeschylus' Characteristics.—It remains to say a word on two more points: the religious ideas of Aeschylus and some of the main characteristics of his poetry. The religious aspect of the drama in one sense was prominent from the first. But the new spirit imported by the genius of Aeschylus was religious in a profounder meaning of the term. The sadness of human lot, the power and mysterious dealings of the gods, their terrible and inscrutable wrath and jealousy (*aga* and *phthonos*), their certain vengeance upon sinners, all the more fearful if delayed—such are the poet's constant themes, especially in the *Oresteia*. And at times, particularly in the *Trilogy*, in his reference to the divine power of Zeus, he almost approaches a stern and sombre monotheism.

One specially noteworthy point in the *Agamemnon* is his ex-

PLICIT repudiation of the common Hellenic view that prosperity brings ruin. In other places he seems to share the feeling; but here (*Ag.* 730) he goes deeper, and declares that it is not *δλβος* but always wickedness that brings about men's fall. All through there is a recurring note of *fear* in his view of man's destiny. In one remarkable passage of the *Eumenides* (517-525) this fear is extolled as a moral power which ought to be enthroned in men's hearts, to deter them from impious acts or from the pride that impels them to such sins.

Of the poetic qualities of Aeschylus' drama and diction, both in the lyrics and the dialogue, the briefest word must here suffice. He is everywhere distinguished by grandeur and power of conception, presentation and expression, and most of all in the latest works, the *Prometheus* and the *Trilogy*. He is pre-eminent in depicting the slow approach of fear, as in the *Persae*; the imminent horror of impending fate, as in the broken cries and visions of Cassandra in the *Agamemnon* (1072-1177), the long lament and prayers to the nether powers in the *Choephoroe* (315-478), and the gradual rousing of the slumbering Furies in the *Eumenides* (117-139). The fatal end in these tragedies is foreseen; but the effect is due to its measured advance, to the slowly darkening suspense which no poet has more powerfully rendered. Again, he is a master of contrasts, as when the floating vision of consoling nymphs appears to the tortured Prometheus (115-135); or the unmatched lyrics which tell (in the *Agamemnon*, 228-247) of the death of Iphigeneia; or the vision of his lost love that the night brings to Menelaus (410-426). And not least noticeable is the extraordinary range force and imaginativeness of his diction. One example of his lyrics may be given which will illustrate more than one of these points. It is taken from the lament in the *Septem*, sung by the chorus and the two sisters, while following the funeral procession of the princes. (*Sept.* 854-860):—

Nay, with the wafting gale of your sighs, my sisters,
Beat on your heads with your hands the stroke as of oars,
The stroke that passes ever across Acheron,
Speeding on its way the black-robed sacred bark,—
The bark Apollo comes not near,
The bark that is hidden from the sunlight—
To the shore of darkness that welcomes all! (A. Sr.)

BIBLIOGRAPHY.—*Authorities:* The chief authority for the text is a single ms. at Florence, of the early 11th century, known as the Medicean or M., written by a professional scribe and revised by a contemporary scholar, who corrected the copyist's mistakes, added the scholia, the arguments and the *dramatis personae* of three plays (*Theb.*, *Agam.*, *Eum.*), and at the end of the *Life of Aeschylus* and the *Catalogue* of his dramas. The ms. has also been further corrected by later hands. In 1896 the Italian Ministry of Public Instruction published the ms. in photographic facsimile, with an instructive preface by Signor Rostagno. Besides M. there are some eight later mss. (13th to 15th century), and numerous copies of the three select plays (*Sept.*, *Pers.*, *Prom.*) which were most read in the later Byzantine period. These later mss. are of little value.

Editions.—The three first printed copies (Aldine, 1518; Turnebus and Robertello, 1552) give only those parts of *Agamemnon* found in M., from which mss. some leaves were lost; in 1557 the full text was restored by Vettori (Victorius) from later mss. After these four, the chief editions of the seven plays were those of Schütz, Porson, Butler, Wellauer, Dindorf, Bothe, Ahrens, Paley, Hermann, Hartung, Weil, Merkel, Kirchhoff and Wecklein. Editions of separate plays, special studies, etc. Wilamowitz-Moellendorf, Enger, Conington, Blaydes, Cobet, Meineke, Madvig, Ellis, W. Headlam, Davies, Tucker, Verrall, Haigh and Hoernle. The *Fragmenta* have been edited by Nauck and also by Wecklein. The Aeschylean staging is discussed in Albert Müller's *Lehrbuch der griechischen Bühnenalterthümer*; in "Die Bühne des Aeschylos," by Wilamowitz (*Hermes*, xxi.); in Smith's *Dict. of Antiquities*, art. "Theatrum" (R. C. Jebb); in Dörpfeld and Reisch (*Das griechische Theater*), Haigh's *Attic Theatre*, and Gardner and Jevons' *Manual of Greek Antiquities*. English verse translations: *Agamemnon*, Milman and R. Browning; *Oresteia*, *Suppliants*, *Persae*, *Seven against Thebes*, *Prometheus Vincit*, by E. D. A. Morshead; *Prometheus*, E. B. Browning; the whole seven plays, Lewis Campbell. *Oresteia* by G. Murray, by R. C. Trevelyan, by G. M. Cookson; prose translation by W. G. and C. E. S. Headlam.

AESCULAPIUS, the Latin form of *ASKLEPIOS* (*Ἀσκληπίος*) the name of the Greek god of medicine, the son of Apollo and the nymph Coronis. He probably came from Thessaly. The centaur Cheiron taught him the art of healing. At length Zeus, who, being afraid that he might render all men immortal, slew him with a thunderbolt (Apollodorus iii. 10; Pindar, *Phthia*, 3; Diod. Sic. iv.

71). Homer mentions him as a skilful physician, whose sons, Machaon and Podaleirius, are physicians in the Greek camp before Troy (*Iliad*, ii. 731). Temples were erected to Asklepios in many parts of Greece, near healing springs or on high mountains. The practice of sleeping (*incubatio*) in these sanctuaries was very common, it being supposed that the god effected cures or prescribed remedies to the sick in dreams. All who were healed offered sacrifice (especially a cock) and hung up votive tablets, recording their names, their diseases, and the manner in which they had been cured. Many of these tablets have been discovered at Epidaurus, the god's most famous shrine. Herodas (*Mimes*, 4) gives a description of one of his temples, and of the offerings made to him. The cult of Asklepios was introduced into Rome by order of the Sibylline books (293 B.C.), to avert a pestilence. The god was fetched from Epidaurus in the form of a snake and a temple assigned him on an island in the Tiber (Livy x. 47; Ovid, *Metam.* xv. 622). Asklepios is commonly represented standing, dressed in a long cloak, with bare breast; his usual attribute is a club-like staff with a serpent coiled round it. He is often accompanied by Telesphorus, the boy genius of healing, and his daughter, Hygieia, the goddess of health. Votive reliefs representing such groups have been found near the temple of Asklepios at Athens.

AESERNIA (mod. *Isernia*), a Samnite town 58m. N.E. of Beneventum on the road to Corfinium, at the junction of a road past Venafrum to the Via Latina. These routes are all followed by railways to Campobasso, Sulmona and Caianello. A Roman colony from 263 B.C., it became the headquarters of the Italian revolt after the loss of Corfinium, and was only recovered by Sulla at the end of the war, in 80 B.C. Massive ancient walls serve as foundation to modern ones.

AESOP (Gr. *Ἀἴσωπος*), author of *Fables* about animals, generally with a didactic purpose, which have given their name to a whole class of stories, is supposed to have lived from about 620 to 560 B.C. The place of his birth is uncertain. He was the slave of Iadmon of Samos and met with a violent death at the hands of the inhabitants of Delphi. When a pestilence came upon them, the Delphians offered compensation for his death, and the award was claimed by Iadmon, grandson of his old master. Herodotus, who is authority for this (ii. 134), does not state the cause of Aesop's death; various reasons are assigned by later writers—his insulting sarcasms, the embezzlement of money entrusted to him by Croesus for distribution at Delphi (Schol. Ar. Vesp. 1446), the theft of a silver cup. Aesop must have been freed by Iadmon, or he could not have conducted the public defence of a Samian demagogue (Aristotle, *Rhetoric*, ii. 20). Legend says that he afterwards lived at the court of Croesus, where he met Solon, and dined in the company of the Seven Sages of Greece with Periander at Corinth. But it is impossible to say whether there is any grain of fact in this confused chronology. During the reign of Peisistratus he is said to have visited Athens, on which occasion he related the fable of *The Frogs asking for a King*, to dissuade the citizens from changing Peisistratus for another ruler.

The current stories about him are derived from a life, or rather

romance, prefixed to a book of fables, purporting to be his, collected by Maximus Planudes, a monk of the 14th century. This describes him as ugly and deformed, as he is represented in the marble figure in the Villa Albani at Rome. That this life, however, was in existence a century before Planudes, appears from a 13th-century ms. of it found at Florence. In Plutarch's *Symposium of the Seven Sages*, at which Aesop is a guest, there are jests on his original servile condition, but nothing derogatory is said about his personal appearance. We are further told that the Athenians set up a noble statue of him by Lysippus, which furnishes a strong argument against the fiction of his deformity. The obscurity in which the history of Aesop is involved has induced some scholars to deny his existence altogether.

It is probable that Aesop did not commit his fables to writing (*Wasps*, 1259; Plato, *Phaedo*, 61 b). Demetrius of Phalerum (345–283 B.C.) made a collection in ten books, probably in prose, which has been lost. Next appeared an edition in elegiac verse, cited by Suidas, but the author's name is unknown. Babrius, a Roman, turned the fables into choliambics in the earlier part of the 3rd century A.D. The most celebrated of the Latin adapters is Phaedrus, a freedman of Augustus. Avianus (of uncertain date, perhaps the 4th century) translated 42 fables into Latin elegiacs. The collections, which we possess under the name of *Aesop's Fables*, are late renderings of Babrius's version, or Babrius was translated into Syriac, and back again into Greek. Ignatius Diaconus, in the 9th century, made a version of 53 fables in choliambic tetrameters. Stories from Oriental sources were added, and from these collections Maximus Planudes made and edited the collection which has come down to us under the name of Aesop, and from which the popular fables of modern Europe have been derived.

BIBLIOGRAPHY.—For further information see the article **FABLE**; Bentley, *Dissertation on the Fables of Aesop*; Du Ménil, *Poésies inédites du moyen âge* (1854); J. Jacobs, *The Fables of Aesop* (1889); i. The history of the Aesopic fable; ii. The Fables of Aesop, as first printed by William Caxton (1484), from his French translation; Hervieux, *Les Fabulistes Latins* (1893–99). Before any Greek text appeared, a Latin translation of 100 *Fabulae Aesopicae* by an Italian scholar named Ranuzio (Renutius) was published at Rome, 1476. About 1480 the collection of Planudes was brought out at Milan by Buono Accorso (Accursius), together with Ranuzio's translation. This edition, which contained 144 fables, was frequently reprinted and additions were made from time to time from various mss.—the Heidelberg (Palatine), Florentine, Vatican and Augsburg—by Stephanus (1547), Nevelet (1610), Hudson (1718), Hauptmann (1741), Furia (1810), Coray (1810), Schneider (1812) and others. A critical edition of all the previously known fables, prepared by Carl von Halm from the collections of Furia, Coray and Schneider, was published in the Teubner series of Greek and Latin texts. A *Fabularum Aesopicarum sylloge* (233 in number) from a Paris ms., with critical notes by Sternbach, appeared in a Cracow university publication, *Rozprawy akademii umiejetnosci* (1894).

AESOPUS, a Greek historian who wrote a history of Alexander the Great, a Latin translation of which, by Julius Valerius, was discovered by Mai in 1816. He is known as the pseudo-Callisthenes.

(See the references s.v. **CALLISTHENES**.)

AESOPUS, CLODIUS, Roman tragedian, flourished in the first century B.C. Cicero was on friendly terms with him. Aesopus made a last appearance in 55 B.C.—when Cicero tells us that he was advanced in years—on the occasion of the splendid games given by Pompey at the dedication of his theatre. Horace (*Sat.* iii. 3. 239) mentions his taking a pearl from the ear-drop of Caecilia Metella and dissolving it in vinegar, that he might have the satisfaction of swallowing eight thousand pounds' worth at a draught.

AESTHETICS. If we examine a poem in order to determine what it is that makes us feel it to be a poem, we at once find two constant and necessary elements: a complex of *images*, and a *feeling* that animates them. Let us, for instance, recall a passage learnt at school: Virgil's lines (*Aeneid*, iii., 294, sqq.), in which Aeneas describes how on hearing that in the country to whose shores he had come the Trojan Helenus was reigning, with Andromache, now his wife, he was overcome with amazement

and a great desire to see this surviving son of Priam and to hear of his strange adventures. Andromache, whom he meets outside the walls of the city, by the waters of a river renamed Simois, celebrating funeral rites before a cenotaph of green turf and two altars to Hector and Astyanax; her astonishment on seeing him, her hesitation, the halting words in which she questions him, uncertain whether he is a man or a ghost; Aeneas's no less agitated replies and interrogations, and the pain and confusion with which she recalls the past—how she lived through scenes of blood and shame, how she was assigned by lot as slave and concubine to Pyrrhus, abandoned by him and united to Helenus, another of his slaves, how Pyrrhus fell by the hand of Orestes and Helenus became a free man and a king; the entry of Aeneas and his men into the city, and their reception by the son of Priam in this little Troy, this mimic Pergamon with its new Xanthus, and its Scaean Gate whose threshold Aeneas greets with a kiss—all these details, and others here omitted, are images of persons, things, attitudes, gestures, sayings, joy and sorrow; mere images, not history or historical criticism, for which they are neither given nor taken. But through them all there runs a feeling, a feeling which is our own no less than the poet's, a human feeling of bitter memories, of shuddering horror, of melancholy, of homesickness, of tenderness, of a kind of childish *pietas* that could prompt this vain revival of things perished, these playthings fashioned by a religious devotion, the *parva Troia*, the *Pergama simulata magnis*, the *arentem Xanthi cognomine rivum*: something inexpressible in logical terms, which only poetry can express in full. Moreover, these two elements may appear as two in a first abstract analysis, but they cannot be regarded as two distinct threads, however intertwined; for, in effect, the feeling is altogether converted into images, into this complex of images, and is thus a feeling that is contemplated and therefore resolved and transcended. Hence poetry must be called neither feeling, nor image, nor yet the sum of the two, but "contemplation of feeling" or "lyrical intuition" or (which is the same thing) "pure intuition"—pure, that is, of all historical and critical reference to the reality or unreality of the images of which it is woven, and apprehending the pure throb of life in its ideality. Doubtless, other things may be found in poetry besides these two elements or moments and the synthesis of the two; but these other things are either present as extraneous elements in a compound (reflections, exhortations, polemics, allegories, etc.), or else they are just these image-feelings themselves taken in abstraction from their context as so much material, restored to the condition in which it was before the act of poetic creation. In the former case, they are non-poetic elements merely interpolated into or attached to the poem; in the latter, they are divested of poetry, rendered unpoetical by a reader either unpoetical or not at the moment poetical, who has dispelled the poetry, either because he cannot live in its ideal realm, or for the legitimate ends of historical enquiry or other practical purposes which involve the degradation—or rather, the conversion—of the poem into a document or an instrument.

Artistic Qualities.—What has been said of "poetry" applies to all the other "arts" commonly enumerated; painting, sculpture, architecture, music. Whenever the artistic quality of any product of the mind is discussed, the dilemma must be faced, that either it is a lyrical intuition, or it is something else, something just as respectable, but not art. If painting (as some theorists have maintained) were the imitation or reproduction of a given object, it would be, not art, but something mechanical and practical; if the task of the painter (as other theorists have held) were to combine lines and lights and colours with ingenious novelty of invention and effect, he would be, not an artist, but an inventor; if music consisted in similar combinations of notes, the paradox of Leibniz and Father Kircher would come true, and a man could write music without being a musician; or alternatively we should have to fear (as Proudhon did for poetry and John Stuart Mill for music) that the possible combinations of words or notes would one day be exhausted, and poetry or music would disappear. As in poetry, so in these other arts, it is notorious that foreign elements sometimes intrude themselves; foreign either *a parte*

objecti or *a parte subjecti*, foreign either in fact or from the point of view of an inartistic spectator or listener. Thus the critics of these arts advise the artist to exclude, or at least not to rely upon, what they call the "literary" elements in painting, sculpture and music, just as the critic of poetry advises the writer to look for "poetry" and not be led astray by mere literature. The reader who understands poetry goes straight to this poetic heart and feels its beat upon his own; where this beat is silent, he denies that poetry is present, whatever and however many other things may take its place, united in the work, and however valuable they may be for skill and wisdom, nobility of intellect, quickness of wit and pleasantness of effect. The reader who does not understand poetry loses his way in pursuit of these other things. He is wrong not because he admires them, but because he thinks he is admiring poetry.

Other Forms of Activity As Distinct from Art.—By defining art as lyrical or pure intuition we have implicitly distinguished it from all other forms of mental production. If such distinctions are made explicit, we obtain the following negations:

1. *Art is not philosophy*, because philosophy is the logical thinking of the universal categories of being, and art is the unreflective intuition of being. Hence, while philosophy transcends the image and uses it for its own purposes, art lives in it as in a kingdom. It is said that art cannot behave in an irrational manner and cannot ignore logic; and certainly it is neither irrational nor illogical; but its own rationality, its own logic, is a quite different thing from the dialectical logic of the concept, and it was in order to indicate this peculiar and unique character that the name "logic of sense" or "aesthetic" was invented. The not uncommon assertion that art has a logical character, involves either an equivocation between conceptual logic and aesthetic logic, or a symbolic expression of the latter in terms of the former.

2. *Art is not history*, because history implies the critical distinction between reality and unreality; the reality of the fact and the reality of a fancied world: the reality of action and the reality of desire. For art, these distinctions are as yet unmade; it lives, as we have said, upon pure images. The historical existence of Helenus, Andromache and Aeneas makes no difference to the poetical quality of Virgil's poem. Here, too, an objection has been raised: namely that art is not wholly indifferent to historical criteria, because it obeys the laws of "verisimilitude"; but, here again, "verisimilitude" is only a rather clumsy metaphor for the mutual coherence of images, which without this internal coherence would fail to produce their effect as images, like Horace's *delphinus in silvis* and *aper in fluctibus*.

3. *Art is not natural science*, because natural science is historical fact classified and so made abstract; nor is it *mathematical science*, because mathematics performs operations with abstractions and does not contemplate. The analogy sometimes drawn between mathematical and poetical creation is based on merely external and generic resemblances; and the alleged necessity of a mathematical or geometrical basis for the arts is only another metaphor, a symbolic expression of the constructive, cohesive and unifying force of the poetic mind building itself a body of images.

4. *Art is not the play of fancy*, because the play of fancy passes from image to image, in search of variety, rest or diversion, seeking to amuse itself with the likenesses of things that give pleasure or have an emotional and pathetic interest; whereas in art the fancy is so dominated by the single problem of converting chaotic feeling into clear intuition, that we recognize the propriety of ceasing to call it fancy and calling it imagination, poetic imagination or creative imagination. Fancy as such is as far removed from poetry as are the works of Mrs. Radcliffe or Dumas père.

5. *Art Is Not Feeling in Its Immediacy.*—Andromache, on seeing Aeneas, becomes *amens*, *dirigit visu in medio, labitur, longo vix tempore fatur*, and when she speaks *longos ciebat incassum fletus*; but the poet does not lose his wits or grow stiff as he gazes; he does not totter or weep or cry; he expresses himself in harmonious verses, having made these various perturbations the object of which he sings. Feelings in their immediacy are "expressed"

for if they were not, if they were not also sensible and bodily facts ("psycho-physical phenomena," as the positivists used to call them) they would not be concrete things, and so they would be nothing at all. Andromache expressed herself in the way described above. But "expression" in this sense, even when accompanied by consciousness, is a mere metaphor from "mental" or "aesthetic expression" which alone really expresses, that is, gives to feeling a theoretical form and converts it into words, song and outward shape. This distinction between contemplated feeling, or poetry, and feeling enacted or endured, is the source of the power, ascribed to art, of "liberating us from the passions" and "calming" us (the power of *catharsis*), and of the consequent condemnation, from an aesthetic point of view, of works of art, or parts of them, in which immediate feeling has a place or finds a vent. Hence, too, arises another characteristic of poetic expression—really synonymous with the last—namely its "infinity" as opposed to the "finitude" of immediate feeling or passion; or, as it is also called, the "universal" or "cosmic" character of poetry. Feeling, not crushed but contemplated by the work of poetry, is seen to diffuse itself in widening circles over all the realm of the soul, which is the realm of the universe, echoing and re-echoing endlessly: joy and sorrow, pleasure and pain, energy and lassitude, earnestness and frivolity, and so forth, are linked to each other and lead to each other through infinite shades and gradations; so that the feeling, while preserving its individual physiognomy and its original dominating motive, is not exhausted by or restricted to this original character. A comic image, if it is poetically comic, carries with it something that is not comic, as in the case of Don Quixote or Falstaff; and the image of something terrible is never, in poetry, without an atoning element of loftiness, goodness and love.

6. *Art is not instruction or oratory*: it is not circumscribed and limited by service to any practical purpose whatever, whether this be the inculcation of a particular philosophical, historical or scientific truth, or the advocacy of a particular way of feeling and the action corresponding to it. Oratory at once robs expression of its "infinity" and independence, and, by making it the means to an end, dissolves it in this end. Hence arises what Schiller called the "non-determining" character of art, as opposed to the "determining" character of oratory; and hence the justifiable suspicion of "political poetry"—political poetry being, proverbially, bad poetry.

7. As art is not to be confused with the form of practical action most akin to it, namely instruction and oratory, so *a fortiori*, it must not be confused with other forms directed to the production of certain effects, whether these consist in pleasure, enjoyment and utility, or in goodness and righteousness. We must exclude from art not only meretricious works, but also those inspired by a desire for goodness, as equally, though differently, inartistic and repugnant to lovers of poetry. Flaubert's remark that indecent books lacked *vérité*, is parallel to Voltaire's gibe that certain "poésies sacrées" were really "sacrées, car personne n'y touche."

Art in Its Relations.—The "negations" here made explicit are obviously, from another point of view, "relations"; for the various distinct forms of mental activity cannot be conceived as separate each from the rest and acting in self-supporting isolation. This is not the place to set forth a complete system of the forms or categories of the mind in their order and their dialectic; confining ourselves to art, we must be content to say that the category of art, like every other category, mutually presupposes and is presupposed by all the rest: it is conditioned by them all and conditions them all. How could the aesthetic synthesis, which is poetry, arise, were it not preceded by a state of mental commotion? *Si vis me flere, dolendum est*, and so forth. And what is this state of mind which we have called feeling, but the whole mind, with its past thoughts, volitions and actions, now thinking and desiring and suffering and rejoicing, travelling within itself? Poetry is like a ray of sunlight shining upon this darkness, lending it its own light and making visible the hidden forms of things. Hence it cannot be produced by an empty and dull mind; hence those artists who embrace the creed of pure art or art for

art's sake, and close their hearts to the troubles of life and the cares of thought, are found to be wholly unproductive, or at most rise to the imitation of others or to an impressionism devoid of concentration. Hence the basis of all poetry is human personality, and, since human personality finds its completion in morality, the basis of all poetry is the moral consciousness. Of course this does not mean that the artist must be a profound thinker or an acute critic; nor that he must be a pattern of virtue or a hero; but he must have a share in the world of thought and action which will enable him, either in his own person or by sympathy with others, to live the whole drama of human life. He may sin, lose the purity of his heart, and expose himself, as a practical agent, to blame; but he must have a keen sense of purity and impurity, righteousness and sin, good and evil. He may not be endowed with great practical courage; he may even betray signs of timidity and cowardice; but he must feel the dignity of courage. Many artistic inspirations are due, not to what the artist, as a man, is in practice, but to what he is not, and feels that he ought to be admiring and enjoying the qualities he lacks when he sees them in others. Many, perhaps the finest, pages of heroic and warlike poetry are by men who never had the nerve or the skill to handle a weapon. On the other hand, we are not maintaining that the possession of a moral personality is enough to make a poet or an artist. To be a *vir bonus* does not make a man even an orator, unless he is also *dicendi peritus*. The *sine qua non* of poetry is poetry, that form of theoretical synthesis which we have defined above; the spark of poetical genius without which all the rest is mere fuel, not burning because no fire is at hand to light it. But the figure of the pure poet, the pure artist, the votary of pure Beauty, aloof from contact with humanity, is no real figure but a caricature.

That poetry not only presupposes the other forms of human mental activity but is presupposed by them, is proved by the fact that without the poetic imagination which gives contemplative form to the workings of feeling, intuitive expression to obscure impressions, and thus becomes representations and words, whether spoken or sung or painted or otherwise uttered, logical thought could not arise. Logical thought is not language, but it never exists without language, and it uses the language which poetry has created; by means of concepts, it discerns and dominates the representations of poetry, and it could not dominate them unless they, its future subjects, had first an existence of their own. Further, without the discerning and criticizing activity of thought, action would be impossible; and if action, then good action, the moral consciousness, duty. Every man, however much he may seem to be all logical thinker, critic, scientist, or all absorbed in practical interests or devoted to duty, cherishes at the bottom of his heart his own private store of imagination and poetry; even Faust's pedantic *famulus*, Wagner, confessed that he often had his "grillenhafte Stunden." Had this element been altogether denied him, he would not have been a man, and therefore not even a thinking or acting being. This extreme case is an absurdity; but in proportion as this private store is scanty, we find a certain superficiality and aridity in thought, and a certain coldness in action.

The Science of Art, or Aesthetics, and Its Philosophical Character.—The concept of art expounded above is in a sense the ordinary concept, which appears with greater or less clarity in all statements about art, and is constantly appealed to, explicitly or implicitly, as the fixed point round which all discussions on the subject gravitate: and this, not only nowadays, but at all times, as could be shown by the collection and interpretation of things said by writers, poets, artists, laymen and even the common people. But it is desirable to dispel the illusion that this concept exists as an innate idea, and to replace this by the truth, that it operates as an *a priori* concept. Now an *a priori* concept does not exist by itself, but only in the individual products which it generates. Just as the *a priori* reality called Art, Poetry or Beauty does not exist in a transcendent region where it can be perceived and admired in itself, but only in the innumerable works of poetry, of art and of beauty which it has formed and continues to form, so the logical *a priori* concept of art exists nowhere but in the par-

ticular judgments which it has formed and continues to form, the refutations which it has effected and continues to effect, the demonstrations it makes, the theories it constructs, the problems and groups of problems, which it solves and has solved. The definitions and distinctions and negations and relations expounded above have each its own history, and have been progressively worked out in the course of centuries, and in them we now possess the fruits of this complex and unremitting toil. Aesthetic, or the science of art, has not therefore the task (attributed to it by certain scholastic conceptions) of defining art once for all and deducing from this conception its various doctrines, so as to cover the whole field of aesthetic science; it is only the perpetual systematization, always renewed and always growing, of the problems arising from time to time out of reflection upon art, and is identical with the solutions of the difficulties and the criticisms of the errors which act as stimulus and material to the unceasing progress of thought. This being so, no exposition of aesthetic (especially a summary exposition such as can alone be given here) can claim to deal exhaustively with the innumerable problems which have arisen and may arise in the course of the history of aesthetics; it can only mention and discuss the chief, and among these, by preference, those which still make themselves felt and resist solution in ordinary educated thought; adding an implied "et cetera," so that the reader may pursue the subject according to the criteria set before him, either by going again over old discussions, or by entering into those of to-day, which change and multiply and assume new shapes almost daily. Another warning must not be omitted: namely that aesthetics, though a special philosophical science, having as its principle a special and distinct category of the mind, can never, just because it is philosophical, be detached from the main body of philosophy; for its problems are concerned with the relations between art and the other mental forms, and therefore imply both difference and identity. Aesthetics is really the whole of philosophy, but with special emphasis on that side of it which concerns art. Many have demanded or imagined or desired a self-contained aesthetics, devoid of any general philosophical implications, and consistent with more than one, or with any, philosophy; but the project is impossible of execution because self-contradictory. Even those who promise to expound a naturalistic, inductive, physical, physiological or psychological aesthetics—in a word, a non-philosophical aesthetics—when they pass from promise to performance surreptitiously introduce a general positivistic, naturalistic or even materialistic philosophy. And anyone who thinks that the philosophical ideas of positivism, naturalism and materialism are false and out of date, will find it an easy matter to refute the aesthetic or pseudo-aesthetic doctrines which mutually support them and are supported by them, and will not regard their problems as problems still awaiting solution or worthy of discussion—or, at least, protracted discussion. For instance, the downfall of psychological associationism (or the substitution of mechanism for a *priori* synthesis) implies the downfall not only of logical associationism but of aesthetics also, with its association of "content" and "form," or of two "representations," which (unlike Campanella's *tactus intrinsecus*, effected *cum magna suavitate*) was a *contactus extrinsecus* whose terms were no sooner united than they *discedebant*. The collapse of biological and evolutionary explanations of logical and ethical values implies the same collapse in the case of aesthetic value. The proved inability of empirical methods to yield knowledge of reality, which in fact they can only classify and reduce to types, involves the impossibility of an aesthetics arrived at by collecting aesthetic facts in classes and discovering their laws by induction.

Intuition and Expression.—One of the first problems to arise, when the work of art is defined as "lyrical image," concerns the relation of "intuition" to "expression" and the manner of the transition from the one to the other. At bottom this is the same problem which arises in other parts of philosophy: the problem of inner and outer, of mind and matter, of soul and body, and, in ethics, of intention and will, will and action, and so forth. Thus stated, the problem is insoluble; for once we have divided the inner from the outer, body from mind, will from

action, or intuition from expression, there is no way of passing from one to the other or of reuniting them, unless we appeal for their reunion to a third term, variously represented as God or the Unknowable. Dualism leads necessarily either to transcendence or to agnosticism. But when a problem is found to be insoluble in the terms in which it is stated the only course open is to criticize these terms themselves, to inquire how they have been arrived at, and whether their genesis was logically sound. In this case, such inquiry leads to the conclusion that the terms depend not upon a philosophical principle, but upon an empirical and naturalistic classification, which has created two groups of facts called internal and external respectively (as if internal facts were not also external, and as if an external fact could exist without being also internal), or souls and bodies, or images and expressions; and everyone knows that it is hopeless to try to find a dialectical unity between terms that have been distinguished not philosophically or formally but only empirically and materially. The soul is only a soul in so far as it is a body; the will is only a will in so far as it moves arms and legs, or is action; intuition is only intuition in so far as it is, in that very act, expression. An image that does not express, that is not speech, song, drawing, painting, sculpture or architecture—speech at least murmured to oneself, song at least echoing within one's own breast, line and colour seen in imagination and colouring with its own tint the whole soul and organism—is an image that does not exist. We may assert its existence, but we cannot support our assertion; for the only thing we could adduce in support of it would be the fact that the image was embodied or expressed. This profound philosophical doctrine, the *identity of intuition and expression* is, moreover, a principle of ordinary common sense, which laughs at people who claim to have thoughts they cannot express or to have imagined a great picture which they cannot paint. *Rem tene, verba sequuntur*; if there are no *verba*, there is no *res*. This identity, which applies to every sphere of the mind, has in the sphere of art a clearness and self-evidence lacking, perhaps, elsewhere. In the creation of a work of poetry, we are present, as it were, at the mystery of the creation of the world; hence the value of the contribution made by aesthetics to philosophy as a whole, or the conception of the One that is All. Aesthetics, by denying in the life of art an abstract spiritualism and the resulting dualism, prepares the way and leads the mind towards idealism or absolute spiritualism.

Expression and Communication.—Objections to the identity of intuition and expression generally arise from psychological illusions which lead us to believe that we possess at any given moment a profusion of concrete and lively images, when in fact we only possess signs and names for them; or else from faulty analysis of cases like that of the artist who is believed to express mere fragments of a world of images that exists in his mind in its entirety, whereas he really has in his mind only these fragments, together with—not the supposed complete world, but at most an aspiration or obscure working towards it, towards a greater and richer image which may take shape or may not. But these objections also arise from a confusion between *expression* and *communication*, the latter being really distinct from the image and its expression. Communication is the fixation of the intuition-expression upon an object metaphorically called material or physical; in reality, even here we are concerned not with material or physical things but with a mental process. The proof that the so-called physical object is unreal, and its resolution into terms of mind, is primarily of interest for our general philosophical conceptions, and only indirectly for the elucidation of aesthetic questions; hence for brevity's sake we may let the metaphor or symbol stand and speak of matter or nature. It is clear that the poem is complete as soon as the poet has expressed it in words which he repeats to himself. When he comes to repeat them aloud, for others to hear, or looks for someone to learn them by heart and repeat them to others as in a *schola cantorum*, or sets them down in writing or in printing, he has entered upon a new stage, not aesthetic but practical, whose social and cultural importance need not, of course, be insisted upon. So with the painter; he paints on his panel or canvas, but

he could not paint unless at every stage in his work, from the original blur or sketch to the finishing touches, the intuited image, the line and colour painted in his imagination, preceded the brush-stroke. Indeed, when the brush-stroke outruns the image, it is cancelled and replaced by the artist's correction of his own work. The exact line that divides expression from communication is difficult to draw in the concrete case, for in the concrete case the two processes generally alternate rapidly and appear to mingle, but it is clear in idea, and it must be firmly grasped. Through overlooking it, or blurring it through insufficient attention, arise the confusions between *art* and *technique*. Technique is not an intrinsic element of art but has to do precisely with the concept of communication. In general it is a cognition or complex of cognitions disposed and directed to the furtherance of practical action; and, in the case of art, of the practical action which makes objects and instruments for the recording and communicating of works of art; e.g., cognitions concerning the preparation of panels, canvases or walls to be painted, pigments, varnishes, ways of obtaining good pronunciation and declamation and so forth. Technical treatises are not aesthetic treatises, nor yet parts or chapters of them. Provided, that is, that the ideas are rigorously conceived and the words used accurately in relation to them it would not be worth while to pick a quarrel over the use of the word "technique" as a synonym for the artistic work itself, regarded as "inner technique" or the formation of intuition-expressions. The confusion between art and technique is especially beloved by impotent artists, who hope to obtain from practical things and practical devices and inventions the help which their strength does not enable them to give themselves.

Artistic Objects: the Theory of the Special Arts, and the Beauty of Nature.—The work of communicating and conserving artistic images, with the help of technique, produces the material objects metaphorically called "*artistic objects*" or "*works of art*": pictures, sculptures and buildings, and, in a more complicated manner, literary and musical writings, and, in our own times, gramophones and records which make it possible to reproduce voices and sounds. But neither these voices and sounds nor the symbols of writing, sculpture and architecture, are works of art; works of art exist only in the minds that create or recreate them. To remove the appearance of paradox from the truth that beautiful objects, beautiful things, do not exist, it may be opportune to recall the analogous case of economic science, which knows perfectly well that in the sphere of economics there are no naturally or physically *useful* things, but only demand and labour, from which physical things acquire, metaphorically, this epithet. A student of economics who wished to deduce the economic value of things from their physical qualities would be perpetrating a gross *ignoratio elenchi*.

Yet this same *ignoratio elenchi* has been, and still is, committed in aesthetic, by the theory of special arts, and the limits or peculiar aesthetic character of each. The divisions between the arts are merely technical or physical, according as the artistic objects consist of physical sounds, notes, coloured objects, carved or modelled objects, or constructed objects having no apparent correspondence with natural bodies (poetry, music, painting, sculpture, architecture, etc.). To ask what is the artistic character of each of these arts, what it can and cannot do, what kinds of images can be expressed in sounds, what in notes, what in colours, what in lines, and so forth, is like asking in economics what things are entitled by their physical qualities to have a value and what are not, and what relative values they are entitled to have; whereas it is clear that physical qualities do not enter into the question, and anything may be desired or demanded or valued more than another, or more than anything else at all, according to circumstances and needs. Even Lessing found himself slipping down the slope leading to this truth, and was forced to such strange conclusions as that actions belonged to poetry and bodies to sculpture; even Richard Wagner attempted to find a place in the list for a comprehensive art, namely Opera, including in itself by a process of aggregation the powers of all the arts. A reader with any artistic sense finds in a single solitary line from a poet at once musical and picturesque qualities, sculptural strength and

architectural structure; and the same with a picture, which is never a mere thing of the eyes but an affair of the whole soul, and exists in the soul not only as colour but as sound and speech. But when we try to grasp these musical or picturesque or other qualities, they elude us and turn into each other, and melt into a unity, however we may be accustomed to distinguish them by different names; a practical proof that art is one and cannot be divided into arts. One, and infinitely varied; not according to the technical conceptions of the several arts, but according to the infinite variety of artistic personalities and their states of mind.

With this relation (and confusion) between artistic creations and instruments of communication or *objets d'art* must be connected the problem of *natural beauty*. We shall not discuss the question, raised by certain aestheticians, whether there are in nature other poets, other artistic beings, beside man; a question which ought to be answered in the affirmative not only out of respect for the song-birds, but, still more, out of respect for the idealistic conception of the world as life and spirituality throughout; even if (as the fairy-tale goes) we have lost the magic herb which when we put it in our mouth, gives us the power of understanding the language of animals and plants. The phrase *natural beauty* properly refers to persons, things and places whose effect is comparable to that of poetry, painting, sculpture and the other arts. There is no difficulty in allowing the existence of such "natural *objets d'art*," for the process of poetic communication may take place by means of objects naturally given as well as by means of objects artificially produced. The lover's imagination creates a woman beautiful to him, and personifies her in Laura; the pilgrim's imagination creates the charming or sublime landscape, and embodies it in the scene of a lake or a mountain; and these creations of theirs are sometimes shared by more or less wide social circles, thus becoming the "professional beauties" admired by everyone and the famous "views" before which all experience a more or less sincere rapture. No doubt, these creations are mortal; ridicule sometimes kills them, satiety may bring neglect, fashion may replace them by others; and—unlike works of art—they do not admit of authentic interpretation. The bay of Naples, seen from the height of one of the most beautiful Neapolitan villas, was after some time described by the Russian lady who owned the villa as *une cuvette bleue*, whose blue encircled by green so wearied her that she sold the villa. But even the *cuvette bleue* was a legitimate poetical creation.

Literary Kinds and Aesthetic Categories.—Effects at once greater and more detrimental upon the criticism and historical study of art and literature have been produced by a theory of similar but slightly different origin, the theory of *literary and artistic kinds*. This, like the foregoing, is based on a classification in itself justifiable and useful. The foregoing is based on a technical or physical classification of artistic objects; this is based on a classification according to the feelings which form their content or motive, into *tragic, comic, lyrical, heroic, erotic, idyllic, romantic* and so on, with divisions and subdivisions. It is useful in practice to distribute an artist's works, for purposes of publication, into these classes, putting lyrics in one volume, dramas in another, poems in a third and romances in a fourth; and it is convenient, in fact, indispensable, to refer to works and groups of works by these names in speaking and writing of them. But here again we must deny and pronounce illegitimate the transition from these classificatory concepts to the poetic laws of composition and aesthetic criteria of judgment, as when people try to decide that a tragedy must have a subject of a certain kind, characters of a certain kind, a plot of a certain kind and a certain length; and, when confronted by a work, instead of looking for and appraising its own poetry, ask whether it is a tragedy or a poem, and whether it obeys the "laws" of one or other "kind." The literary criticism of the 19th century owed its great progress largely to its abandonment of the criteria of kinds, in which the criticism of the Renaissance and the French classicists had always been entangled, as may be seen from the discussions arising out of the poems of Dante, Ariosto and Tasso, Guarini's *Pastor fido*, Corneille's *Cid*, and Lope de Vega's *comedias*. Artists have profited by this liberation less than critics; for anyone with

artistic genius bursts the fetters of such servitude, or even makes them the instruments of his power; and the artist with little or no genius turns his very freedom into a new slavery.

It has been thought that the divisions of kinds could be saved by giving them a philosophical significance; or at any rate one such division, that of lyric, epic and dramatic, regarded as the three moments of a process of objectification passing from the lyric, the outpouring of the ego, to the epic, in which the ego detaches its feeling from itself by narrating it, and thence to the drama, in which it allows this feeling to create of itself its own mouthpieces, the *dramatis personae*. But the lyric is not a pouring-forth; it is not a cry or a lament; it is an objectification in which the ego sees itself on the stage, narrates itself, and dramatizes itself; and this lyrical spirit forms the poetry both of epic and of drama, which are therefore distinguished from the lyric only by external signs. A work which is altogether poetry, like *Macbeth* or *Antony and Cleopatra*, is substantially a lyric in which the various tones and successive verses are represented by characters and scenes.

In the old aesthetics, and even to-day in those which perpetuate the type, an important place is given to the so-called categories of beauty: the *sublime*, the *tragic*, the *comic*, the *graceful*, the *humorous* and so forth, which German philosophers not only claimed to treat as philosophical concepts, whereas they are really mere psychological and empirical concepts, but developed by means of that dialectic which belongs only to pure or speculative concepts, philosophical categories. Thus they arranged them in an imaginary progress culminating now in the Beautiful, now in the Tragic, now in the Humorous. Taking these concepts at their face value, we may observe their substantial correspondence with the concepts of the literary and artistic kinds; and this is the source from which, as excerpts from manuals of literature, they have found their way into philosophy. As psychological and empirical concepts, they do not belong to aesthetics; and as a whole, in their common quality, they refer merely to the world of feelings, empirically grouped and classified, which forms the permanent matter of artistic intuition.

Rhetoric, Grammar and Philosophy of Language.—Every error has in it an element of truth, and arises from an arbitrary combination of things which in themselves are legitimate. This principle may be confirmed by an examination of other erroneous doctrines which have been prominent in the past and are still to a less degree prominent to-day. It is perfectly legitimate, in teaching people to write, to make use of distinctions like that between simple style, ornate style and metaphorical style and its forms, and to point out that here the pupil ought to express himself literally and there metaphorically, or that here the metaphor used is incoherent or drawn out to excessive length, and that here the figure of "preterition," there "hypotyposis" or "irony," would have been suitable. But when people lose sight of the merely practical and didactic origin of these distinctions and construct a philosophical theory of form as divisible into simple form and ornate form, logical form and affective form, and so forth, they are introducing elements of rhetoric into aesthetics and vitiating the true concept of expression. For expression is never logical, but always affective, that is, lyrical and imaginative; and hence it is never metaphorical but always "proper"; it is never simple in the sense of lacking elaboration, or ornate in the sense of being loaded with extraneous elements; it is always adorned with itself, *simplex munditiis*. Even logical thought or science, so far as it is expressed, becomes feeling and imagination, which is why a philosophical or historical or scientific book can be not only true but beautiful, and must always be judged not only logically but also aesthetically. Thus we sometimes say that a book is a failure as theory, or criticism, or historical truth, but a success as a work of art, in view of the feeling animating it and expressed in it. As for the element of truth which is obscurely at work in this distinction between logical form and metaphorical form, dialectic and rhetoric, we may detect in it the need of a science of aesthetics side by side with that of logic; but it was a mistake to try to distinguish the two sciences within the sphere of expression which belongs to one of them alone.

Another element in education, namely the teaching of languages, has no less legitimately, ever since ancient times, classified expressions into periods, propositions and words, and words into various species, and each species according to the variations and combinations of roots and suffixes, syllables and letters; and hence have arisen alphabets, grammars and vocabularies, just as in another way for poetry has arisen a science of prosody, and for music and the figurative and architectural arts there have arisen musical and pictorial grammars and so forth. But here, too, the ancients did not succeed in avoiding an illegitimate transition *ab intellectu ad rem*, from abstractions to reality, from the empirical to the philosophical, such as we have already observed elsewhere; and this involved thinking of speech as an aggregation of words, and words as aggregations of syllables or of roots and suffixes; whereas the *prius* is speech itself, a continuum, resembling an organism, and words and syllables and roots are a *posterius*, an anatomical preparation, the product of the abstracting intellect, not the original or real fact. If grammar, like rhetoric in the case above considered, is transplanted into aesthetic, the result is a distinction between expression and the means of expression, which is a mere reduplication; for the means of expression are just expression itself, broken into pieces by grammarians. This error, combined with the error of distinguishing between simple and ornate form, has prevented people from seeing that the philosophy of language is not a philosophical grammar, but is wholly devoid of grammatical elements. It does not raise grammatical classifications to a philosophical level; it ignores them, and, when they get in its way, destroys them. The philosophy of language, in a word, is identical with the philosophy of poetry and art, the science of intuition-expression, aesthetics; which embraces language in its whole extension, passing beyond the limits of phonetic and syllabic language, and in its unimpaired reality as living and completely significant expression.

Classical and Romantic.—The problems reviewed above belong to the past—a past extending through centuries—rather than to the present; of their mis-stated questions and misconceived solutions there now remain mere relics and superstitions which affect academic treatises more than they do the consciousness and culture of ordinary people. But it is necessary to watch carefully for new shoots from the old stock, which still appear from time to time, in order to cut them down. Such is, in our own time, the theory of styles applied to the history of art (Wölfflin and others) and extended to the history of poetry (Strick and others), a new irruption of rhetorical abstractions into the judgment and history of works of art. But the chief problem of our time, to be overcome by aesthetics, is connected with the crisis in art and in judgments upon art produced by the romantic period. Not that this crisis was not foreshadowed by precedents and parallels in earlier history, like Alexandrian art and that of the late Roman period, and in modern times the Baroque art and poetry which followed upon that of the Renaissance. The crisis of the romantic period, together with sources and characteristics peculiar to itself, had a magnitude all of its own. It asserted an antithesis between *naïve* and *sentimental* poetry, *classical* and *romantic* art, and thus denied the unity of art and asserted a duality of two fundamentally different arts, of which it took the side of the second, as that appropriate to the modern age, by upholding the primary importance in art of feeling, passion and fancy. In part this was a justifiable reaction against the rationalistic literature of classicism in the French manner, now satirical, now frivolous, weak in feeling and imagination and deficient in a deep poetic sense; but in part, *romanticism* was a rebellion not against *classicism* but against the classical as such: against the idea of the serenity and infinity of the artistic image, against catharsis and in favour of a turbid emotionalism that could not and would not undergo purification. This was very well understood by Goethe, the poet both of passion and of serenity, and therefore, because he was a poet, a classical poet; who opposed romantic poetry as "hospital poetry." Later, it was thought that the disease had run its course and that romanticism was a thing of the past; but though some of its contents and some of its forms were dead, its soul was not: its soul consisting in this tendency on the part of art towards

an immediate expression of passions and impressions. Hence it changed its name but went on living and working. It called itself "realism," "verism," "symbolism," "artistic style," "impressionism," "sensualism," "imagism," "decadentism," and nowadays, in its extreme forms, "expressionism" and "futurism." The very conception of art is attacked by these doctrines, which tend to replace it by the conception of one or other kind of non-art; and the statement that they are fighting against art is confirmed by the hatred of the extremists of this movement for museums and libraries and all the art of the past—that is, for the idea of art which on the whole corresponds with art as it has been historically realized. The connection of this movement, in its latest modern form, with industrialism and the psychology produced and fostered by industrialism is obvious. What art is contrasted with is practical life as lived to-day; and art, for this movement, is not the expression of life and hence the transcending of life in the contemplation of the infinite and universal, but the cries and gesticulations and broken colours of life itself. The real poets and artists, on the other hand, rare at any time, naturally continue, nowadays as always, to work according to the old and only idea of what art is, expressing their feelings in harmonious forms; and the real connoisseurs (rarer, these also, than people think) continue to judge their work according to this same idea. In spite of this, the tendency to destroy the idea of art is a characteristic of our age; and this tendency is based on the *proton pseudos* which confuses mental or aesthetic expression with natural or practical expression—the expression which passes confusedly from sensation to sensation and is a mere effect of sensation, with the expression which art elaborates, as it builds, draws, colours or models, and which is its beautiful creation. The problem for aesthetics to-day is the reassertion and defence of the classical as against romanticism: the synthetic, formal theoretical element which is the *proprium* of art, as against the affective element which it is the business of art to resolve into itself, but which to-day has turned against it and threatens to displace it. Against the inexhaustible fertility of creative mind, the gates of hell shall not prevail; but the hostility which endeavours to make them prevail is disturbing, even if only in an incidental manner, the artistic taste, the artistic life and consequently the intellectual and moral life of to-day.

The Criticism and History of Art and Literature.—Another group of questions raised in works on aesthetics, though not unsuitable to such works, properly belongs to logic and the theory of historical thought. These concern the aesthetic judgment and the history of poetry and the arts. By showing that the aesthetic activity (or art) is one of the forms of mind, a value, a category, or whatever we choose to call it, and not (as philosophers of various schools have thought) an empirical concept referable to certain orders of utilitarian or mixed facts, by establishing the *autonomy of aesthetic value*, aesthetics has also shown that it is the predicate of a special judgment, the *aesthetic judgment*, and the subject-matter of history, of a special history, the history of poetry and the arts, *artistic and literary history*.

The questions that have been raised concerning the aesthetic judgment and artistic and literary history are making allowance for the peculiar character of art, identical with the methodological questions that arise in every field of historical study. It has been asked whether the aesthetic judgment is *absolute* or *relative*; but every historical judgment (and the aesthetic judgment affirming the reality and quality of aesthetic facts is an historical judgment) is always both absolute and relative at once: absolute, in so far as the category involved in the construction possesses universal truth; relative, in so far as the object constructed by that category is historically conditioned: hence in the historical judgment the category is individualized and the individual becomes absolute. Those who in the past have denied the absoluteness of the aesthetic judgment (sensationalistic, hedonistic or utilitarian aestheticians) denied in effect the quality, reality and autonomy of art. It has been asked whether a knowledge of the history of the time—the whole history of the time in question—is necessary for the aesthetic judgment of the art of that time; it certainly is, because, as we know, poetic creation presupposes

all the rest of the mind which it is converting into lyrical imagery, and the one aesthetic creation presupposes all the other creations (passions, feelings, customs, etc.) of the given historical moment. Hence may be seen the error both of those who advocate a merely historical judgment upon art (historical critics) and of those who advocate a merely aesthetic (aesthetic critics). The former would find in art all the rest of history (social conditions, biography of the artist, etc.), but would omit that part which is proper to art; the latter would judge the work of art in abstraction from history, depriving it of its real meaning and giving it an imaginary meaning or testing it by arbitrary standards. Lastly, there has appeared a kind of scepticism or pessimism as to the possibility of understanding the art of the past; a scepticism or pessimism which in that case ought to extend to every part of history (history of thought, politics, religion and morality), and refutes itself by a *reductio ad absurdum*, since what we call contemporary art and history really belong to the past as much as those of more distant ages, and must, like them, be re-created in the present, in the mind that feels them and the intellect that understands them. There are artistic works and periods that remain to us unintelligible; but this only means that we are not now in a position to enter again into their life and to understand them, and the same is true of the ideas and customs and actions of many peoples and ages. Humanity, like the individual, remembers some things and forgets many others; but it may yet, in the course of its mental development, reach a point where its memory of them revives.

A final question concerns the form proper to artistic and literary history, which, in the form that arose in the romantic period, and still prevails to-day, expounds the history of works of art as a function of the concepts and social needs of its various periods, regarding them as aesthetic expressions of these things and connecting them closely with civil history. This tends to obscure and almost to render invisible the peculiar character of the individual work of art, the character which makes it impossible to confuse one work of art with any other, and results in treating them as documents of social life. In practice no doubt this method is tempered by what may be called the "individualizing" method, which emphasizes the individual character of the works; but the mixture has the defects of all eclecticism. To escape this, there is nothing to do but consistently to develop individualizing history, and to treat works of art not in relation to social history but as each a world in itself, into which from time to time the whole of history is concentrated, transfigured and imaginatively transcended in the individuality of the poetic work, which is a creation, not a reflection, a monument, not a document. Dante is not simply a document of the middle ages, nor Shakespeare of the English Renaissance; as such, they have many equals or superiors among bad poets and non-poets. It has been objected that this method imposed on artistic and literary history the form of a series of disconnected essays or monographs; but, obviously, the connection is provided by human history as a whole, of which the personalities of poets constitute a part, and a somewhat conspicuous part (Shakespearian poetry is an event no less important than the Reformation or the French Revolution), and, precisely because they are a part of it, they ought not to be submerged and lost in it, that is, in its other parts, but ought to retain their proper proportions and their original character.

History of Aesthetics.—From the character of aesthetics as a philosophical science (*see above*) it follows that its history cannot be separated from that of philosophy at large, from which aesthetics receives light and guidance, and gives back light and guidance in its turn. The so-called subjectivist tendency which modern philosophy acquired with Descartes, for instance, by promoting enquiry into the creative power of the mind, indirectly promoted enquiry into the aesthetic power; and conversely, as an example of the influence of aesthetic on the rest of philosophy, it is enough to recall the effect which the mature consciousness of creative imagination and poetic logic had in liberating philosophical logic from the traditional intellectualism and formalism, and raising it to the level of speculative or dialectical logic in

the philosophies of Schelling and Hegel. But if the history of aesthetics must be seen as a part of the entire history of philosophy, it must on the other hand be enlarged beyond its boundaries as ordinarily defined, which would restrict it almost entirely to the series of works by so-called professional philosophers and of the academic treatises known as "systems of philosophy." Genuine and original philosophical thought is often to be found, alive and energetic in books not written by professional philosophers and not outwardly systematic; ethical thought, in works of asceticism and religion; political, in the works of historians; aesthetic, in those of art-critics, and so forth. Further, it must be remembered that, strictly speaking, the subject-matter of the history of aesthetics is not the problem, the single problem, of the definition of art, a problem exhausted when that definition has been or shall have been attained; but the innumerable problems which are perpetually springing up in connection with art, in which this one problem, the problem of defining art, acquires particularity and concreteness, and in which alone it truly exists. Subject to these warnings, which must be carefully borne in mind, a general sketch of the history of aesthetics may be given, to provide a preliminary orientation, without running the risk of being understood in an unduly rigid and simplifactory manner.

A sketch of this kind must accept, not merely as convenient for purposes of exposition but as historically true, the common statement that aesthetics is a modern science. Graeco-Roman antiquity did not speculate about art, or speculated very little; its chief concern was to create a method of artistic instruction, not a "philosophy" but an "empirical science" of art. Such are the ancient treatises on "grammar," "rhetoric," "institutions of oratory," "architecture," "music," "painting" and "sculpture"; the basis of all later methods of instruction, even those of to-day, in which the old principles are restated and interpreted *cum grano salis*, but not abandoned, because in practice they are indispensable. The philosophy of art did not find favourable or stimulating conditions in ancient philosophy, which was primarily "physics" and "metaphysics," and only secondarily and intermittently "psychology" or more precisely "philosophy of mind." To the philosophical problems of aesthetics it only referred in passing, either negatively, in Plato's denial of the value of poetry, or positively, in Aristotle's defence, which attempted to secure for poetry a realm of its own between that of history and that of philosophy, or again in the speculations of Plotinus, who for the first time united the previously disconnected concepts of "art" and "the beautiful." Other important thoughts of the ancients were that to poetry belonged "tales" (*μῦθοι*) and not "arguments" (*λόγοι*), and that "semantic" (rhetorical or poetical) propositions were to be distinguished from "apophantic" (logical). Lately an almost wholly unexpected strain of ancient aesthetic thought has come to light, in the Epicurean doctrines expounded by Philodemus, in which imagination is conceived in what seems almost a romantic way. But these observations remained, for the time being, practically sterile; and the ancients' firm and sure judgment in artistic matters was never raised to the level and consistency of a theory, owing to an obstacle of a general nature—the objectivistic or naturalistic character of ancient philosophy, whose removal was only commenced, or demanded, by Christianity when it brought the problems of the soul into the focus of thought.

But even Christian philosophy, partly through its predominant transcendence, mysticism and asceticism, partly through the scholastic form which it borrowed from ancient philosophy and with which it remained content, while it raised the problems of morality in an acute form, and handled them with delicacy, did not penetrate deeply into the mental region of imagination and taste, just as it avoided the region which corresponds to it in the sphere of practice, the region of passions, interests, utility, politics and economics. Just as politics and economics were conceived moralistically, so art was subordinated to moral and religious allegory; and the germs of aesthetics scattered through the ancient writers were forgotten or only superficially remembered. The philosophy of the Renaissance, with its return to naturalism, revived, interpreted and adapted the ancient poetics

and rhetorics and treatises on the arts; but though it laboured long at "verisimilitude" and "truth," "imitation" and "the idea," "beauty" and the mystical theory of beauty and love, "catharsis" or the purgation of passion, and the problems of the literary kinds, traditional and modern, it never reached a new and fruitful principle. No thinker arose capable of doing for the Renaissance treatises on poetry and art what Machiavelli did for political science, asserting with emphasis, not merely by the way and as an admission, its original and autonomous character.

Much more important in this respect, though its importance was long overlooked by historians, was the thought of the later Renaissance, known in Italy as the *seicento*, Baroque, or the literary and artistic decadence. This was the time at which the distinction was first insisted upon between the "intellect" and a faculty called *ingegno*, *ingenium*, "wit" or "genius," as especially inventive of art; and, corresponding to this, a faculty of judgment, which was not ratiocination or logical judgment, because it judged "without discourse" or "without concepts," and came to be called "taste." These terms were reinforced by another, which appeared to denote something not determinable in logical concepts and in some way mysterious: "*nescio quid*" or "*je ne sais quoi*"; an expression particularly frequent in Italy (*non so che*), and imitated in other countries. At the same time were sung the praises of the enchantress "imagination," of the "sensible" or "sensuous" element in poetic imagery, and of the miracles of "colour," in painting, as opposed to "drawing" which seemed not altogether free from an element of cold logic. These new intellectual tendencies were somewhat turbid, but at times were purified and raised to the level of reasoned theory, e.g., Zuccolo (1623), who criticized "metric art" and replaced its criteria by the "judgment of sense," which to him meant not the eye or the ear but a higher power united to the senses; Mascardi (1636), who rejected the objective and rhetorical distinction between the styles, and reduced style to the particular individual manner arising out of the particular "wit" of each writer, thus asserting the existence of as many styles as there are writers; Pallavicino (1644), who criticized "verisimilitude" and assigned to poetry as its proper domain that of "first apprehensions" or imaginations, "neither true nor false"; and Tesauro (1654), who tried to work out a logic of rhetoric as opposed to the logic of dialectic, and extended the rhetorical forms beyond merely verbal form, to pictorial and plastic form.

Cartesianism, to which we have already referred, though, in the hands of Descartes and his successors, hostile to poetry and imagination, from another point of view, as stimulating enquiry into the subject or the mind, helped these scattered efforts (as we have said) to consolidate themselves into a system and to search for a principle to which the arts could be reduced; and here too the Italians, welcoming Descartes' method but not his rigid intellectualism or his contempt for poetry, art and imagination, wrote the first treatises on poetry in which the concept of imagination played a central or leading part (Calopreso 1691, Gravina 1692 and 1708, Muratori 1704 and others). These had considerable influence on Bodmer and the Swiss school, and, through them, on the new German criticism and aesthetics and that of Europe at large; so that a recent writer (Robertson) could speak of "the Italian origin of romantic aesthetics."

These minor theorists led to the work of G. B. Vico, who in his *Scienza nuova* (1725-1730) propounded a "poetic logic" which he distinguished from "intellectual logic"; regarded poetry as a mode of consciousness or theoretic form preceding the philosophical or reasoning form, and asserted as its sole principle the imagination, which is strong in proportion as it is free from ratiocination, its enemy and destroyer; praised as father and prince of all true poets the barbaric Homer, and with him, though impaired by theological and scholastic culture, the half-barbaric Dante; and attempted, though without success, to discern English tragedy and Shakespeare, who, though undiscovered by Vico, would, had he known him, certainly have been his third barbaric and supreme poet. But in aesthetics as elsewhere, Vico in his lifetime founded no school, because he was before his time, and also because his philosophical thought was concealed

beneath a kind of historical symbolism. "Poetic logic" only began to make progress when it reappeared in a far less profound shape, but in a more favourable environment, in the works of Baumgarten, who systematized an aesthetics of a somewhat hybrid Leibnizian origin, and gave it various names, including *ars analogi rationis*, *scientia cognitionis sensitivae*, *gnoseologia inferior*, and the name it has retained, *aesthetica* (*Meditationes*, 1735; *Aesthetica*, 1750-58).

The school of Baumgarten, or (more correctly) of Leibnitz, which both did and did not distinguish imaginative from logical form (for it regarded it as *cognitio confusa* and none the less ascribed to it a *perfectio* of its own), and the current of English aesthetics (Shaftesbury, Hutcheson, Hume, Home, Gerard, Burke, Alison, etc.), together with the essays on beauty and art which abounded at this time, and the theoretical and historical works of Lessing and Winckelmann, contributed to provide the stimulus, partly positive and partly negative, to the formation of the other masterpiece of 18th century aesthetics, the *Critique of Judgment* (1790) by Immanuel Kant, in which the author (after doubting it in the first *Critique*) discovered that beauty and art afford subject-matter for a special philosophical science—in other words, discovered the autonomy of the aesthetic activity. As against the utilitarians he showed that the beautiful pleases "without interest" (i.e., utilitarian interest); against the intellectualists, that it pleases "without concepts"; and further, against both, that it has "the form of purposiveness" without "representation of a purpose"; and, against the hedonists, that it is "the object of a universal pleasure." In substance, Kant never went further than this negative and generic assertion of the beautiful, just as, in the *Critique of Practical Reason*, once he had vindicated the moral law, he did not go beyond the generic form of duty. But the principles he had laid down were laid down once for all. After the *Critique of Judgment*, a return to hedonistic and utilitarian explanations of art and beauty could (and did) take place only through ignorance of Kant's demonstrations. Even the return to Leibnitz and Baumgarten's theory of art as confused or fanciful thinking would have been impossible, had Kant been able to link up his own theory of the beautiful, as pleasing apart from concepts, and as purposiveness without representation of purpose, with Vico's imperfect and inconsistent but powerful theory of the logic of imagination, which was to some extent represented in Germany at this time by Hamann and Herder. But Kant himself prepared the way for the reassertion of the "confused concept" when he ascribed to genius the virtue of combining intellect and fancy, and distinguished art from "pure beauty" by defining it as "adherent beauty."

This return to the tradition of Baumgarten is apparent in post-Kantian philosophy when it regards poetry and art as a form of the knowledge of the Absolute or the Idea, whether equal to philosophy, inferior and preparatory to it, or superior to it as in Schelling's philosophy (1800) where it becomes the organ of the Absolute. In the richest and most striking work of this school, the *Lectures on Aesthetic* of Hegel (1765-1831), art, with religion and philosophy, is placed in the "sphere of absolute mind," where the mind is set free from empirical knowledge and practical action, and enjoys the beatific thought of God or the Idea. It remains doubtful whether the first moment in this triad is art or religion; different expositions of his doctrine by Hegel himself differ in this respect; but it is clear that both, art and religion alike, are at once transcended and included in the final synthesis which is philosophy. This means that art, like religion, is substantially an inferior or imperfect philosophy, a philosophy expressed in imagery, a contradiction between a content and a form inadequate to it which only philosophy can resolve. Hegel, who tended to identify the system of philosophy, the dialectic of concepts, with actual history, expressed this by his famous paradox of the death of art in the modern world, as incapable of subserving the highest interests of the age.

This conception of art as philosophy, or intuitive philosophy, or a symbol of philosophy, or the like, reappears throughout the idealistic aesthetics of the first half of the 19th century, with rare exceptions, e.g., Schleiermacher's *Lectures on Aesthetic* (1825,

1832-33) which we possess in a very incomplete form. In spite of the high merit of these works, and the enthusiasm for poetry and art which they express, the reaction against this type of aesthetics was, at bottom, a reaction against the artificial character of the principle on which they were based. This reaction took place in the second half of the century, simultaneously with the general reaction against the idealistic philosophy of the great post-Kantian systems. This anti-philosophical movement certainly had its significance as a symptom of discontent and of a desire to find new paths; but it did not produce an aesthetics correcting the errors of its predecessors and carrying the problem a stage further. In part, it was a breach in the continuity of thought; in part, a hopeless attempt to solve the problems of aesthetics, which are philosophical problems, by the methods of empirical science (e.g., Fechner); in part, a revival of hedonistic and utilitarian aesthetic by a utilitarianism resting on association of ideas, evolution and a biological theory of heredity (e.g., Spencer). Nothing of real value was added by the *epigoni* of idealism (Vischer, Schasler, Carriere, Lotze, etc.), or the followers of the other early 19th century philosophical movements, e.g., the so-called formalistic aesthetics (Zimmermann) derived from Herbart, or the eclectics and psychologists, who, like all the rest, laboured at two abstractions, "content" and "form" ("aesthetics of content" and "aesthetics of form"), and sometimes tried to fasten the two together, failing to see that by so doing they were only uniting two fictions into a third. The best thoughts on art in this period are to be found not in the professional philosophers or aestheticians but in the critics of poetry and art, e.g., De Sanctis in Italy, Baudelaire and Flaubert in France, Pater in England, Hanslick and Fiedler in Germany, Julius Lange in Holland, etc. These writers alone make amends for the aesthetic trivialities of the positivistic philosophers and the empty artificiality of the so-called idealists.

The general revival of speculative thought led to greater successes in aesthetics in the first decades of the 20th century. Especially noteworthy is the union which is taking place between aesthetics and the philosophy of language, facilitated by the difficulties under which linguistic, conceived as the naturalistic and positivistic science of the phonetic laws of language and similar abstractions, is labouring. But the most recent aesthetic productions, because they are recent and still in process of development, cannot as yet be historically placed and judged.

BIBLIOGRAPHY.—The chief monuments of aesthetic thought have already been referred to in the foregoing outline. It may be added that the latest revision of the text of Aristotle's *Poetics*, together with a commentary, is that of A. Rostagni (Turin, 1927), and that the fragments of the Epicurean aesthetic of Philodemus (polemic against Neoplatonism of Parium) have been edited by Jensen (*Philodemus über die Gedichte Fünftes Buch*, Berlin, 1923). Of Vico's second *Scienza nuova* the complete critical edition is that of F. Nicolini (Bari, 1911-16). Of Baumgarten, there is a reprint of the *Meditationes philosophicae de nonnullis ad poema pertinentibus* (1735), edited by Croce, Naples, 1900; but the *Aesthetica*, a very rare book, has unfortunately not been reprinted, though a previously unpublished course of Baumgarten's lectures on aesthetics has been published by B. Poppe (*A. G. Baumgarten: Berne-Leipzig, 1907*). Of Hegel's *Vorlesungen über die Aesthetik*, which we possess in Hotho's redaction (ed. 2, Berlin, 1842-43), Lasson's new edition has not yet appeared.

For the history of aesthetics, R. Zimmermann, *Geschichte der Aesthetik als philosophischer Wissenschaft* (Wien, 1858) and M. Schasler, *Kritische Geschichte der Aesthetik* (Berlin, 1872) may be consulted, though their standards of judgment are now out of date. See also B. Bosanquet, *A History of Aesthetic* (London, 1922). A history of aesthetics is contained in the second part of B. Croce's *Estetica come scienza dell'espressione e linguistica generale* (Bari, 1902; ed. 5, 1922; Eng. trans., abridged, London, 1915; 2nd ed., complete, 1922), and an essay completing and correcting this work, entitled *Inizio, periodi e caratteri della Estetica*, in the same author's *Nuovi saggi di Estetica* (ed. 2, Bari, 1926), which contains the most mature form of the writer's theoretical and historical thought on the subject. For ancient aesthetics Ed. Müller, *Geschichte der Theorie der Kunst bei den Alten* (Breslau, 1831-37), is still very useful; among recent works, E. Panovski, *Idea* (Leipzig, 1924) and A. Rostagni, "Per un'estetica dell'intuizione presso gli antichi" (in *Atene e Roma*, a review of classical philology, Florence, 1920); Aristotele e l'aristotelismo nella storia dell'*Estetica antica* (Florence, 1921). For mediaeval aesthetics the best work is contained in books on Dante, e.g., Vossler's; cf. also Comparetti, *Virgilio nel medio evo* (ed. 2, Florence, 1896) vol. i. For Renaissance aesthetics, J. E. Spingarn, *A History of Literary Criticism*

in the Renaissance (New York, 1899); K. Borinski, *Die Poetik der Renaissance und die Anfänge der literarischen Kritik in Deutschland* (Berlin, 1896). For the Italian *seicento*, Croce, *Storia, cit.*, and essays in *Problemi di Estetica* (ed. 2, Bari, 1923) and *Storia dell'età barocca in Italia* (Bari, 1928); J. M. Robertson, *Studies in the Genesis of Romantic Theory* (London, 1923); H. Quigley, *Italy and the Rise of a New School of Criticism in the 18th Century* (Glasgow, 1921). For Vico's aesthetics, B. Croce, *La filosofia di G. B. Vico* (ed. 2, Bari, 1922; Eng. trans. London, 1913). For German 18th century aesthetics, R. Sommer, *Grundzüge einer Geschichte der deutschen Psychologie und Aesthetik von Wolf-Baumgarten bis Kant-Schiller* (Würzburg, 1892). For the origin of Kant's aesthetics, O. Schlapp, *Kants Lehre vom Genie und die Entstehung der Kritik der Urtheilskraft* (Göttingen, 1901). For that of Schiller, V. Basch, *La poétique de Schiller* (ed. 2, Paris, 1911). For the Hegelian aesthetics the old but penetrating study of Th. W. Danzel, *Über die Aesthetik des hegelischen Philosophie* (Hamburg, 1844), must not be forgotten. For English aesthetics, A. E. Powell (Mrs. Dodds), *The Romantic Theory of Poetry* (London, 1926). For the *Epigoni* of idealism, E. v. Hartmann (who was one of them), *Die deutsche Aesthetik seit Kant* (Berlin, 1886). For recent aesthetics: H. Wildon Carr, *The Philosophy of B. Croce: The Problem of Art and History* (1917); E. F. Carritt, *The Theory of Beauty* (ed. 2, London, 1923); R. G. Collingwood, *Outlines of a Philosophy of Art* (1925). For the history of the philosophy of language in the idealistic period (Hamann, Herder, Humboldt) cf. H. Steinthal, *Ursprung der Sprache* (ed. 4, Berlin, 1888); *Geschichte der Sprachwissenschaft bei den Griechen und Römern* (ed. 2, Berlin, 1890-1891). For recent philosophy of language as aesthetics, Croce, *op. cit.*, and the works of Vossler, Spitzer, Lerch, Bertoni, Bartoli, etc. (B. Cr.)

AESTHETICS, EXPERIMENTAL. Great artists throughout the centuries have contributed to an empirical aesthetic in the broad sense of the term. Some of them have given us extensive treatises based upon an analysis of their own methods of artistic production, or upon an investigation of existing works of art. Hogarth, for example, examined many forms of architecture, as well as the lines of the human figure, in a search for a norm of beauty which he thought eventually he had found in the serpentine line, and Goethe in his *Farbenlehre* has made keen observations in regard to the aesthetics of colour. From the long list of names might also be mentioned Leonardo da Vinci, Sir Joshua Reynolds and M. E. Chevreul. G. Th. Fechner, however, is generally considered the founder of experimental aesthetics. He not only discussed the formal, or direct, and the associative factors underlying beauty on the basis of his experience of works of art, but he devised experiments in order to settle scientifically the question of the most pleasing proportions in geometrical forms and in line division. This problem had engaged the attention of a number of writers, whose results are in strong disagreement. Wolff insisted upon the proportion of 1:1, while Adolf Zeising thought the proportion of the golden section (1:1.618) to be the most pleasing, on the principle that it gives the greatest possible diversity in a harmonious unity. It was the proportion of the golden section that Fechner desired to put to experimental proof. He spread figures of different sizes, such as ellipses, before the observer, with instructions to choose the one which seemed the most pleasing, or he had the person construct a figure according to the most pleasing proportion. It was these two methods of choice and construction, together with that of use, which he proposed as the proper empirical methods of investigation, and these methods have continued to be employed up to the present day. Fechner found the golden section to hold in many instances, but he also found the proportions of 1:1 and 1:3 to be pleasing under certain circumstances. Lightner Witmer thought that Fechner used too few figures, and that the experiments were not properly controlled. He therefore used a serial order of figures with the least perceptible difference of proportion between them. He also had the figures compared in pairs. His results do not always agree with those of Fechner, but he established the importance of the golden section for rectangles and ellipses and line division. An interesting fact came to light in experiments conducted by R. P. Angier. His subjects divided a line at what seemed to them the most pleasing point. Although several persons came near the golden section, no one actually chose it. Nevertheless, the average of all observers was almost exactly the golden section. His results served as a warning not to place too much weight upon averages in the search for an aesthetic norm. In general, however, it may be

said that the golden section and symmetry are pleasing, that a division very near the middle and one which makes the shorter line less than a quarter of the length of the whole line are displeasing.

Numerous experiments have been made upon form and balance, with the principal aim of obtaining a psychological explanation of the pleasing effects. T. H. Haines and A. E. Davies, from their work with a series of cards having a constant length and varying width, decided that eye-movements, associations, balance between forces of attention, and suggestion, were the factors which determined the aesthetic effect. Ethel D. Puffer made an extensive study of balance by the use, among other objects, of lines of various sizes and in various positions. She found that the best aesthetic balance generally corresponded to the mechanical balance, and explained the results in terms of interest which, in the last analysis, meant for her a balance of motor impulses. L. J. Martin asserted that our preference for lines and shapes depends very much upon our attitude toward the objects we are judging. A slanting line, when interpreted as a bad vertical, is displeasing, but when we think of it as a horizontal line which is raising itself to a vertical, it is pleasing. F. Sander believes that absence of feelings of tension produces a restful effect such as is experienced in viewing Greek architecture, while vivid tensions underlie our reactions to Romanesque and Gothic architecture. Th. Lipps's theory of empathy has also frequently been offered as an explanation of aesthetic pleasure in form. It has further been shown that straight, curved or zigzag lines not only give us varying degrees of pleasure, but arouse in us distinct moods.

Colour.—Goethe in his *Farbenlehre* discussed the moods aroused by colours, and the different psychological effects of different colour combinations. Chevreul studied colours from the aesthetic standpoint, and remarked that complementary colours form the most pleasing combinations, as there is a harmony in the contrast, and half a century later Bezold stated that the colours which are very nearly, but not quite, complementary form the best combinations. Towards the end of the last century, Jonas Cohn and August Kirschmann performed controlled experiments on colour in the manner advocated by Fechner. Both men found contrast to be pleasing, and Cohn's results led him to conclude that saturated colours are in most instances preferred. From about this time the number of treatises on colour preferences began to grow rapidly, and the papers have covered a large field of investigation. The effects of hue, saturation and brightness, together with such factors underlying preference as the time of exposure of the colours, suggestion and association, have been studied. A large number of treatises deal with the colour preferences of infants and school children, and the changes in colour preference which occur with age. Comparative studies have also been made of the colour preferences of the sexes and of races. The experiments were done under such widely different conditions that in many cases they are hardly comparable, and the results are so numerous and varied that they are difficult to summarize. In no instance was there any great agreement in regard to the preference either for single colours or for combinations, and often there was not even a great constancy in the choice of the individual observer. All that one can indicate are general tendencies. Red and blue seem to be the favourite colours, and orange and yellow usually rank low. It appears from the mass of information that has been collected that men have the strongest preference for blue and women for red. A typical order of preference is blue, red, purple, green, orange, yellow, which would mean that the colours at the ends of the spectrum have the best chance of being chosen as the most pleasing. Also, saturated colours have a strong attraction, but are not always preferred. As Titchener has remarked, there seem to be two types of observers, one of which prefers saturated colours, the other definitely prefers unsaturated or what are popularly called artistic colours. E. Bullough has made an analysis of the psychological attitude of persons toward colours, and has found that there are four main types of judgments: the objective, where the peculiarities of the colours such as clarity are observed; the physiological, where the aspects of warmth, hardness, etc., are noted; the associative, where the col-

ours remind the observer of some experience; and the character judgment, where the colours are expressive of mood. It seems, then, that our preference depends very much upon our attitude. Indeed, as von Allesch has stated, the old talk of beauty and ugliness of colours has only relative meaning. All colours can be all things at the right moment and at the right place. Nevertheless, we may say that in general complementary colours seem to be pleasing in combination, and probably also those colours which are nearly complementary. On the other hand, colours which are neighbouring in the spectrum do not seem to go together. Harmony, however, can generally be obtained from the inharmonious combination of two colours by the proper selection of a third colour to form a triad.

William Preyer made one of the first investigations of the colour sense of infants. He found yellow to be preferred to blue. William McDougall found that in the fifth month the child's order of preference was red, green, blue. C. S. Myers found that red and green were distinctly preferred to the other colours and to greys. The child examined by C. W. Valentine preferred yellow, then white and pink and then red. T. R. Garth made an investigation of 1,000 white children, and found the order of preference to be blue, green, red, violet, orange, yellow, white. In the investigation of full-blooded Indians, he found the order to be red, blue, violet, green, orange, yellow, white.

Sound.—The most important work on the psychology of music is that of Carl Stumpf. His book *Tonpsychologie* (1890) is a classic in this field and contains, among many theories and facts of importance, his psychological theory of consonance, which is based upon an empirical study of the perception of tonal combinations. For Stumpf, degree of consonance is correlated with degree of fusion of the two tones of a musical interval. In his subsequent writings, he has vigorously attacked the physical theory of consonance of Herman v. Helmholtz and F. E. Krüger. Stumpf has also done extensive work upon the tonal quality of vowels and consonants. One of his latest investigations in the auditory field is a comparison of singing and talking, which he finds not fundamentally different. In speaking we use for the most part a continuous change in tone, while in singing we use discrete tonal steps. H. T. Moore has shown experimentally that, up to a certain point, the pleasantness of tonal intervals grows with our experience of them, which accounts for the gradual change in our attitude toward consonance and dissonance. O. Abraham and E. M. von Hornbostel, in their analysis of tonal intervals, have discovered two factors underlying the experience, one a qualitative, the other a quantitative, which they call distance or width of interval, and accord quality, respectively. C. E. Seashore has devised a series of tests which can be given by means of phonograph records. In his latest work he describes the results obtained by photographing the vibrations of the singing voice. He has detected the presence of the vibrato, or synchronous oscillations of pitch and intensity at the rate of five to eight per second in artistic singing.

In experiments upon the appreciation of pictures the introspective method has usually been employed. O. Külpe showed pictures for three seconds each to a number of persons, and recorded their reports. He did not find evidence of empathy to support Lipps's theory. On the other hand, muscular sensations in a form which, according to Karl Groos, is called inner mimicry are present at times, but not always. A unique method of investigating the effect of pictures upon children was used by R. Schultze, who photographed the children while they were looking at the pictures. One was often able to judge from the photographs which picture the child had been looking at, as well as the mood which had been aroused.

A laboratory research in the field of literature which is suggestive, both from the point of view of method and content, is that of R. C. Givler. He showed conclusively the importance of the mere sound of words in conveying the meaning as well as the moods of poetry. Most of the investigations of the aesthetics and psychology of prose and poetry, however, have been in the nature of a direct analysis of the works themselves, or a study of the life of the artist, and do not come under experimental aes-

thetics in the narrow sense of that term, as used in this article. J. L. Lowes' *The Road to Xanadu* (1927) might, however, be mentioned as a model piece of research of this nature. Comparing the contents of a note-book left by Coleridge with the text of *The Rhymer of the Ancient Mariner* and *Kubla Khan*, Lowes has been able to analyze most convincingly the subconscious mind of that poet. Freud and his followers have also made numerous analyses of the subconscious minds of artists. Their results will undoubtedly be of interest to those persons who believe in the psycho-analytic method, and even the sceptic will find some suggestive material in their writings.

BIBLIOGRAPHY.—For a history of experimental aesthetics up to 1899 the reader is referred to J. Languier des Bancel's article "Les Méthodes de l'esthétique expérimentale" in *L'Année Psychologique*, vi., pp. 144-190 (1899). C. W. Valentine's little work, *An Introduction to the Experimental Psychology of Beauty* (1913), describes a few typical experiments upon colour, form, balance and symmetry, and the aesthetic contemplation of pictures. C. S. Myers's *Text-book of Experimental Psychology*, pt. 1, ch. xxiv. (1922), deals primarily with the methods employed in experimental aesthetics. For a general treatment of psychological aesthetics see W. Wundt, *Physiologische Psychologie*, iii., pp. 123-209 (5th ed., Leipzig, 1902). For a summary of the work on aesthetics of colour see J. H. Parsons, *An Introduction to the Study of Colour Vision* (1924) and M. Luckiesh, *The Language of Colour* (1920). For a history of the problem of tonal intervals see M. Guernsey, "The Role of Consonance and Dissonance in Music," *Amer. J. Psychol.*, xl., pp. 173-204 (1928). The articles of Carl E. Seashore and his pupils upon the experimental psychology of music are to be found in the Iowa Studies in Psychology, *Psychol. Rev. Monog. Suppl.*, Nos. 69, 108, 140, 167, 168. A comprehensive view of the literature upon the dynamic effect of music may be obtained in C. M. Diserens, *The Influence of Music on Behavior* (Princeton, 1926). For the psychology of rhythm see C. M. Ruckmick, "A Bibliography of Rhythm," *Amer. J. Psychol.*, xxiv., pp. 508-519 (1913); xxvi., pp. 457-459 (1915); xxix., pp. 214-218 (1918); xxxv., pp. 407-413 (1924). (H. S. L.)

AESTIVATION, literally "summer residence," a term used in zoology for the condition of torpor into which certain animals pass during the hottest season in hot and dry countries, contrasted with the similar winter condition, hibernation. In botany the word is used of the folded arrangement of the petals in a flower before expansion in the summer, contrasted with "vernation" of leaves which unfold in the spring. See **hibernation**.

AETA, a Negrito tribe of the Philippine Islands, woolly-haired, dark-skinned, dwarfish (the male stature is about 4 ft. 9 in.) inhabiting the mountainous districts of the larger islands and some of the smaller. They are characterized by a large and clumsy foot with abnormally divergent great toe. The social unit is the family; polygamy is permitted, but monogamy prevails. The dead are normally buried, but the bodies of those whom it is wished to honour are exposed on platforms or in trees. Bows and poisoned arrows are used, long spears and darts barbed with flint or shell. Fire is made by means of a flexible thong pulled to and fro in a notch in a cleft stick. They pray to a great serpent to show them yams and honey.

The Aeta were long recognized as the owners of the soil in spite of the arrival of Malayan settlers, and in Luzon they levied taxes upon the Tagalog and other tribes (until these arrived in such numbers as to push them back into the hills) taking the heads of defaulters. For much longer, perhaps even yet, they kept a debit and credit account of heads with the Igorots and other neighbours.

(J. H. H.)

AETHELBALD, king of Mercia, succeeded Ceolred, A.D. 716, at the beginning of the period of Mercian supremacy. His activities as a warrior were slight; in 733 he raided Somerset as far as Somerton, and led unimportant campaigns against the Northumbrians and the Welsh. In 752 Cuthred of Wessex led a successful raid into Oxfordshire against him. Aethelbald encouraged the development of the church, making large grants of land, and publishing a decree in 749 which freed ecclesiastical lands from all obligations to the king except the *trinoda necessitas*.

See Bede, *Hist. Ecc.* (ed. Plummer), v. 23 and *Continuatio s.a.* 740, 750, 757; *Saxon Chronicle* (Earle and Plummer), s.a. 716, 733, 737.

740, 741, 743, 755; Mabillon, *Acta Sanctorum*, ii. pp. 264, 275-276, 279, 283-284; P. Jaffé, *Monumenta Moguntiacae*, iii. pp. 168-177; W. de G. Birch, *Cartul. Saxon.*, 178 (1885-93).

AETHELBALD, king of Wessex, was the son of Aethelwulf, with whom he led the West Saxons to victory against the Danes at Aclea, 851. According to Asser he rebelled against his father on the latter's return from Rome in 856, and deprived him of Wessex, which he ruled until his death in 860. On his father's death in 858 he married his widow, Judith.

See Asser, *Life of Alfred* (W. H. Stevenson, 1904), 12; *Saxon Chronicle*, s.a. 851, 855, 860.

AETHELBERT, king of Kent, son of Eormenric, came to the throne in A.D. 560. Aethelbert's supremacy, described by Bede as extending in 597 to the Humber, can have been little more than nominal, though he exercised stricter sway over Essex, where his nephew, Sabert, was king. An attempt to extend his kingdom westwards was defeated in 568 by Ceawlin at Wibbandune. Aethelbert's reign is chiefly remarkable for the introduction of Christianity. He married a Christian princess, Berta, daughter of Charibert, king of Paris, who brought over a bishop as private confessor. When in 597 Augustine landed in Thanet, the king treated his mission tolerantly, gave him a dwelling in Canterbury and allowed monks to preach there, afterwards being baptized himself, but making no attempt to force conversion on his subjects. In 604 he founded the see of Rochester, and his influence established Mellitus at London in the same year. He published a code of laws, the first of its kind, containing a list of money fines for various offences against the clergy.

BIBLIOGRAPHY.—See Stubbs, *Dict. of Christian Biog. Ethelbert*; Bede, *Hist. Ecc.* (Plummer i. 25, 26, ii. 3, 5); *Saxon Chronicle* (Earle and Plummer), s.a. 568.

AETHELBERT, king of the West Saxons, succeeded to the under-kingdom of Kent during the lifetime of his father, Aethelwulf, and retained it until the death of his elder brother, Aethelbald, in 860, when he became sole king of Wessex and Kent till his death in 865. His reign was marked by two serious attacks by the Danes, who were repelled in 860 by the levies of Hampshire and Berkshire, though not before they had sacked Winchester, while in 865 they ravaged Kent after agreeing to take money for peace. Aethelbert was buried at Sherborne.

BIBLIOGRAPHY.—See the *Saxon Chronicle* (Earle and Plummer), s.a. 860, 865; *King Alfred's Will*; W. de G. Birch, *Cartul. Saxon.*, 553.

AETHELFLAED or **ETHELFLEDA**, the "Lady of the Mercians," the eldest child of Alfred the Great, was married about 886 to Aethelred, earl of Mercia, to whom Alfred entrusted the control of Mercia. On the accession of her brother Edward, Aethelflaed and her husband continued to hold Mercia. In 907 they fortified Chester, and in 909 and 910 either Aethelflaed or her husband must have led the Mercian host at the battles of Tettenhall and Wednesfield (or Tettenhall-Wednesfield, if these battles are one and the same). It was probably about this time that Aethelred fell ill, and the Norwegians and Danes from Ireland unsuccessfully besieged Chester. Aethelflaed won the support of the Danes against the Norwegians, and seems also to have entered into an alliance with the Scots and the Welsh against the pagans.

In 911 Aethelred died, and Edward took over Middlesex and Oxfordshire. Except for this, Aethelflaed's authority remained unimpaired. In 912 she fortified "Scergeat" and Bridgnorth, Tamworth and Stafford in 913, Eddisbury and Warwick in 914, Cherbury, "Weardbyrig" and Runcorn in 915. In 916 she sent an expedition against the Welsh, which advanced as far as Brecknock. In 917 Derby was captured from the Danes, and the next year Leicester and York both submitted to her. She died in 918 at Tamworth (June 12), and was buried in St. Peter's Church at Gloucester. This noble queen, whose career was as distinguished as that of her father and brother, left one daughter, Aelfwyn. For some 18 months Aelfwyn seems to have wielded her mother's authority, and then, just before the Christmas of 919, Edward took Mercia into his own hands, and Aelfwyn was "led away" into Wessex. Aethelflaed and her husband wielded almost kingly authority; the royal title is often given them by the chroniclers.

See *The Saxon Chronicle*, s.a. (especially the Mercian register in MSS. B, C and D); Florence of Worcester; *Fragments of Irish Annals* (ed. O'Connor), pp. 227-237; D.N.B., s.v. (A. M.)

AETHELFRITH, king of Northumbria, is said to have come to the throne in A.D. 593, being the son of Aethelric (probably reigned 568-72). He married Acha, daughter of Ella (Aelle), king of Deira, whom he succeeded, probably in 605, expelling his son Edwin. In 603 he repelled the attack of Aidan, king of the Dalriad Scots, at Daegsastan, defeating him with great loss. Later in his reign, probably in 614, he defeated the Welsh in a great battle at Chester, and massacred the monks at Bangor who were assembled to aid them by their prayers. This war had a strategic importance in the separation of the North Welsh from the Strathclyde Britons. In 617 Aethelfrith was defeated and slain at the river Idle by Raedwald of East Anglia, whom Edwin had persuaded to take up his cause.

See Bede, *Chronica Maiora*, §531; *Hist. Ecc.* (Plummer) i. 34, ii. 2; *Saxon Chronicle*, s.a. 593, 603, 605, 616; *Hist. Brittonum*, §§57, 63; *Annales Cambriae*, s.a. 613.

AETHELING, an Anglo-Saxon word meaning originally "of noble descent," but soon restricted to members of a royal family, and in the *Anglo-Saxon Chronicle* used almost exclusively for members of the royal house of Wessex. It was occasionally used after the Norman Conquest to designate members of the royal family. In the 10th century, the *wergild* of an aetheling was equal to that of an archbishop and one-half of that of a king.

AETHELNOTH (d. 1038), archbishop of Canterbury, known also as EGELNODUS or EDNODUS, was a son of the ealdorman Aethelmaer, and a member of the royal family of Wessex. He became a monk at Glastonbury, then dean of the monastery of Christ Church, Canterbury, and chaplain to King Canute, and on Nov. 13, 1020, he was consecrated archbishop of Canterbury. He appears to have exercised considerable influence over Canute, largely by whose aid he restored his cathedral at Canterbury. Aethelnoth, who was called the "Good," died on Oct. 29, 1038.

AETHELRED, king of Mercia, succeeded his brother Wulfhere in A.D. 675. In 676 he ravaged Kent, destroying the monasteries and churches and taking Rochester. Aethelred married Osthryth, the sister of Egrith, king of Northumbria, but a quarrel arose between the two kings, presumably over the possession of the province of Lindsey, which Egrith had won back at the close of the reign of Wulfhere. In a battle on the banks of the Trent in 679, the king of Mercia was victorious and regained the province. Aelfwine, the brother of Egrith, was slain, but at the intervention of Theodore, archbishop of Canterbury, Aethelred agreed to pay a wergild for the Northumbrian prince and so prevented further hostilities. Osthryth was murdered in 697 and Aethelred abdicated in 704, choosing Coenred as his successor. He then became abbot of Bardney, and, according to Eddius, recommended Wilfrid to Coenred on his return from Rome. Aethelred died at Bardney in 716. See WILFRID.

BIBLIOGRAPHY.—Eddius, *Vita Wilfridi* (Raine), 23, 40, 43, 45-48, 57; Bede, *Hist. Ecc.* (ed. Plummer), iii. 11, iv. 12, 21; *Saxon Chronicle*, s.a. 676, 679, 704, 716. (F. G. M. B.)

AETHELRED I., king of Wessex and Kent (866-871), was the fourth son of Aethelwulf of Wessex, and should, by his father's will, have succeeded to Wessex on the death of his eldest brother Aethelbald. He seems, however, to have stood aside in favour of his brother Aethelbert, king of Kent, to whose joint kingdoms he succeeded in 866. Aethelred's reign was one long struggle against the Danes. In the year of his succession a large Danish force landed in East Anglia, and in the year 868 Aethelred and his brother Alfred went to help Burgred, or Burhred, of Mercia, against this host, but the Mercians soon made peace with their foes. In 871 the Danes encamped at Reading, where they defeated Aethelred and his brother, but later in the year the English won a great victory at "Aescdesdun." A fortnight later they were defeated at Basing, but partially retrieved their fortune by a victory at "Maeretun" (perhaps Marden, in Wiltshire), though the Danes held the field. In the Easter of this year Aethelred died, perhaps of wounds received in the wars against the Danes, and was buried at Wimborne.

AETHELRED II. or ETHELRED (c. 968-1016), king of the English (surnamed **THE UNREADY**; i.e., without *rede* or counsel), son of King Edgar by his second wife, Aelfthryth, was born in 968 or 969 and succeeded to the throne on the murder of his step-brother Edward (the Martyr) in 979. In the year after his accession the Danish invasions recommenced, though as yet their object was plunder only, not conquest. For an account of the repeated invasions, which gathered strength as time went on, see **ENGLISH HISTORY**. Aethelred's policy of buying off the raiders failed, and the massacre of Danes in England carried out by his orders on St. Brice's Day (Dec. 2, 1001) only made matters worse. Next year Sweyn returned, his hostility fanned by the desire for revenge. For two years he ravaged and slew; in 1003 Exeter was destroyed; Norwich and Thetford were sacked in 1004. No effectual resistance was offered, despite efforts here and there; disorganization of the country was complete. In 1005 the Danes were absent in Denmark, but they came back next year, and emboldened by the utter lack of resistance, they ranged far inland. In 1007 Aethelred bought them off for a larger sum than ever (£36,000), and for two years the land enjoyed peace. In 1009, however, in accordance with a resolution made by the witan in the preceding year, Aethelred collected such a fleet "as never before had been in England in any king's day"; but owing to a miserable court quarrel the effort came to nothing. The king then summoned a general levy of the nation, with no better result. Just as he was about to attack, the traitor Edric prevented him from doing so, and the opportunity was lost. In 1010 the Danes returned, to find the kingdom more utterly disorganized than ever. "There was not a chief man in the kingdom who could gather a force, but each fled as he best might; nor even at last would any there resist another." Incapable of offering resistance, the king again offered money, this time no less than £48,000. While it was being collected, the Danes sacked Canterbury and slew the archbishop Alphege. The tribute was paid soon afterwards; and about the same time the Danish leader Thurkill entered the English service.

From 1013 an important change is discernible in the character of the Danish attacks, which now became definitely political in their aim. In this year Sweyn sailed up the Trent and received the submission of northern England, and then, marching south, attacked London. Failing to take it, he hastened west and at Bath received the submission of Wessex. Then he returned northwards, and after that "all the nation considered him as full king." London soon acknowledged him, and Aethelred, after taking refuge for a while with Thurkill's fleet, escaped to Normandy. Sweyn died in Feb. 1014, and Aethelred was recalled by the witan. At once he hastened north against Canute, Sweyn's son, but Canute sailed away, only to return next year, when the traitor Edric joined him and Wessex submitted. Canute and Edric harried Mercia, and were preparing to reduce London, when Aethelred died there on April 23, 1016. Weak, self-indulgent, improvident, he had pursued a policy of opportunism to a fatal conclusion.

Aethelred's wife was Emma, or Aelfgifu, daughter of Richard I. the Fearless, duke of the Normans, whom he married in 1002. After the king's death Emma became the wife of Canute the Great, and after his death in 1035 she struggled hard to secure England for her son, Hardicanute. In 1037, however, when Harold Harefoot became sole king, she was banished; she went to Flanders, returning to England with Hardicanute in 1040. In 1043 Edward the Confessor seized the greater part of Emma's great wealth, and the queen lived in retirement at Winchester until her death on March 6, 1052. By Aethelred Emma had two sons, Edward the Confessor and the aetheling Aelfred (d. 1036), and by Canute she was the mother of Hardicanute. Her marriage with Aethelred was an important step in the history of the relations between England and Normandy, and J. R. Green says "it suddenly opened for its rulers a distinct policy, a distinct course of action, which led to the Norman conquest of England.

From the moment of Emma's marriage Normandy became a chief factor in English politics."

Pertz in the *Scriptores Rerum Germanicarum*, Band xix., Hanover, 1866) for the latter part of the reign. See also J. M. Kemble, *Codex Diplomaticus aevi Saxonici* (London, 1839-48); and B. Thorpe, *Ancient Laws* (London, 1840).

AETHELSTAN (c. 894-940), Saxon king, was the son (probably illegitimate) of Edward the Elder. He had been the favourite of his grandfather Alfred, and was brought up in the household of his aunt Aethelflaed, the "Lady of the Mercians." On the death of his father in 924, Aethelstan succeeded him, and was crowned at Kingston shortly after.

AFTER G. M. COLLEN'S BRIT. SAXONICA

SHIELD OF AETHELSTAN

The cross boutoné, on a field of red and blue, is surmounted by a crest coronet of gold. The circle at the base is gold

time (the exact chronology is uncertain) Aethelstan expelled Sihtric's brother Guthfrith, destroyed the Danish fortress at York, received the submission of the Welsh at Hereford, fixing their boundary along the line of the Wye, and drove the Cornishmen west of the Tamar, fortifying Exeter as an English city. In 934 he invaded Scotland by land and sea, perhaps owing to an alliance between Constantine and Anlaf Sihtricsson. The army advanced as far north as Dunottar, in Kincardineshire, while the navy sailed to Caithness. Simeon of Durham speaks of a submission of Scotland as a result; if it ever took place it was a mere form, for three years later we find a great confederacy formed in Scotland against Aethelstan. This confederacy of 937 was joined by Constantine, king of Scotland, the Welsh of Strathclyde, and the Norwegian chieftains, Anlaf Sihtricsson and Anlaf Godfredsson, who, though they came from Ireland, had powerful English connections. A great battle was fought at Brunanburh (perhaps Brunswark or Birrenswark hill in south-east Dumfriesshire), in which Aethelstan and his brother Edmund were completely victorious. England had been freed from its greatest danger since the days of the struggle of Alfred against Guthrum.

Aethelstan was the first Saxon king who could claim in any real sense to be lord paramount of Britain. In his charters he is continually called "rex totius Britanniae," and he adopts for the first time the Greek title *basileus*. This was not merely an idle flourish, for some of his charters are signed by Welsh and Scottish kings as *subreguli*. Further, Aethelstan was the first king to bring England into close touch with continental Europe. By the marriage of his half-sisters he was brought into connection with the chief royal and princely houses of France and Germany. His sister Eadgifu married Charles the Simple, Eadchild became the wife of Hugh the Great, duke of France, Eadgyth was married to the emperor Otto the Great, and her sister, Aelfgifu, to a petty German prince. Embassies passed between Aethelstan and Harold Fairhair, first king of Norway, with the result that Harold's son Haakon was brought up in England, and is known in Scandinavian history as Haakon Adalsteinsföstri.

Aethelstan died at Gloucester in 940, and was buried at Malmesbury, an abbey which he had munificently endowed during his lifetime. Apparently he was never married, and he certainly had no issue. A considerable body of law has come down to us in Aethelstan's name. The chief collections are those issued at Grately, in Hampshire, at Exeter, at Thunresfeld, and

the *Iudicia civitatis Lundonie*. In the last-named one personal touch is found when the king tells the archbishop how grievous it is to put to death persons of 12 winters for stealing. The king secured the raising of the age limit to 15.

AETHELWEARD or **ETHELWARD**, Anglo-Saxon historian, was the great-grandson of Aethelred, the brother of Alfred, and ealdorman or earl of the western provinces (*i.e.*, probably of the whole of Wessex). He was the author of a Latin chronicle extending to the year 975. Up to the year 892 he is largely dependent on the *Saxon Chronicle*, with a few details of his own; later he is largely independent of it. He was the friend and patron of Aelfric, the grammarian.

AETHELWULF, king of the West Saxons, succeeded his father, Egbert, in A.D. 839. Aethelwulf's reign was chiefly occupied with struggles against the Danes. After the king's defeat 843–44, the Somerset and Dorset levies won a victory at the mouth of the Parret (c. 850). In 851 Ceorl, with the men of Devon, defeated the Danes at Wigganburg, and Aethelstan of Kent was victorious at Sandwich; despite this the Danes wintered in England that year for the first time. In 851 also Aethelwulf and Aethelbald won their great victory at Aclea, probably the modern Ockley. In 853 Aethelwulf subdued the North Welsh, in answer to the appeal of Burgred of Mercia, and gave him his daughter Aethelswith in marriage. The year 855 is the date of the Donation of Aethelwulf and of his journey to Rome with Alfred. On his way home he married Judith, daughter of Charles the Bold. According to Asser he was compelled to give up Wessex to his son Aethelbald on his return, and content himself with the eastern under-kingdom. He died in 858.

See Asser, *Life of Alfred* (W. H. Stevenson, 1904), 1–16; *Saxon Chronicle*, s.a. 823, 836, 840, 851, 853, 855.

AETHER: see **ETHER** (PHYSICS).

AETHICUS (=ETHICUS) **ISTER**, "the philosopher of Istria," the supposed but unknown author of a description of the world written in Greek. An abridgment, under the title of *Cosmographia Ethici*, written in barbarous Latin, and wrongly described as the work of St. Jerome, probably belongs to the 7th century.

The name Aethicus is also attached to a geographical treatise probably dating from the 6th century, a reproduction of the cosmography of Julius Honorius.

AETIOLOGY or **ETIOLOGY**, strictly, science or philosophy of causation, but generally used to denote the part of any special science (and especially of that of medicine and disease) which investigates the causes and origin of its phenomena. An *aetiological myth* is one which is regarded as having been invented *ex post facto* to explain some fact, name, or coincidence, the true account or origin of which has been forgotten. Such myths were often based on grotesque philological analogies, according to which an existing connection between two personalities (cities, etc.) was traced back to a common mythical origin. For a good example of the evolution of such myths see the argument under **AEGINA**, *History*.

AETION or **EETION**, a Greek painter, mentioned by Cicero, Pliny, and Lucian. His most noted work, described in detail by Lucian (*Herodotus or Eetion*, 5), was a picture representing the marriage of Alexander and Roxana. Through a misunderstanding of the words of Lucian, Aetion has been supposed to belong to the age of Antonines; but there can be little doubt

that he was a contemporary of Alexander and of Apelles (Brunn, *Geschichte der griechischen Künstler*, ii. p. 243). Pliny gives his date as 350 B.C.

AETIUS (ah-ët'i-oos) (fl. 350), surnamed "the Atheist," founder of an extreme sect of Arians, was a native of Coele-Syria. He studied successively under the Arians, Paulinus, bishop of Antioch, Athanasius, bishop of Anazarbus, and the presbyter Antonius of Tarsus. At the first synod of Sirmium he won a dialectic victory over the homoiousian bishops, Basilus and Eustathius, who sought in consequence to stir up against him the enmity of Caesar Gallus. In 356 he went to Alexandria with Eunomius (*q.v.*) in order to advocate Arianism, but he was banished by Constantius. Julian recalled him from exile, bestowed upon him an estate in Lesbos, and retained him for a time at his court in Constantinople. At the accession of Valens (364) he retired to his estate at Lesbos, but soon returned to Constantinople, where he died in 367. The Anomoean sect of the Arians, of whom he was leader, are sometimes called after him *Aetians*. His work *De Fide* has been preserved in connection with a refutation written by Epiphanius (*Haer.*, lxxvi. 10).

See A. Harnack, *History of Dogma*, vol. iv. *passim*.

AETIUS (died 454), a Roman general of the closing period of the Western empire, born at Dorostolus in Moesia, late in the 4th century. He was the son of Gaudentius, who, although possibly of barbarian family, rose in the service of the Western empire to be master of the horse, and later, count of Africa. Aetius passed some years as hostage, first with Alaric and the Goths, and later in the camp of Rhuas, king of the Huns, acquiring in this way the knowledge which enabled him afterwards to defeat them. In 424 he led into Italy an army of 60,000 barbarians, mostly Huns, which he employed first to support the *primicerius* Ioannes, who had proclaimed himself emperor, and, on the defeat of the latter, to enforce his claim to the supreme command of the army in Gaul upon Placidia, the empress-mother and regent for Valentinian III. His calumnies against his rival, Count Boniface, which were at first believed by the emperor, led Boniface to revolt and call the Vandals to Africa. Upon the discovery of the truth, Boniface, although defeated in Africa, was received into favour by Valentinian; but Aetius came down against Boniface from his Gallic wars, and in the battle which followed wounded Boniface fatally with his own javelin. From 433 to 450 Aetius was the dominating personality in the Western empire. In Gaul he won his military reputation, upholding for nearly 20 years, by combined policy and daring, the falling fortunes of the empire. His greatest victory was that of Châlons-sur-Marne (Sept. 20, 451), in which he led the Gallic forces against Attila and the Huns. This was the last triumph of the empire. Three years later (454) Aetius presented himself at court to claim the emperor's daughter in marriage for his son Gaudentius; but Valentinian, suspecting him of designs upon the crown, slew him with his own hand.

"That he was the one prop and stay of the Western empire during his life is the unanimous verdict of his contemporaries; but whether he was a really great general or statesman we cannot tell. He was beaten by Boniface; and it was not he, but the Goths and their king, who really triumphed in the Mauriac plain; yet he recovered Gaul in a series of campaigns, and he kept the Visigoths in check. . . . If he was less Roman than his predecessor Constantius, he was far more Roman than his successor Ricimer; and if he had occasionally used the arms of the Huns for his own ends, he had also used them to maintain the empire. One merit he had which must count for much—the merit of recognizing and encouraging men of ability. Majorian and Marcellinus, two of the finest figures in the history of the fallen empire, were men of his training." (Ernest Barker in *Cambridge Mediaeval Hist.*, vol. i., I., 418–419.)

See T. Hodgkin, *Italy and her Invaders*, vols. i. and ii. (1880).

AETIUS, a Greek physician, born at Amida in Mesopotamia, flourished at the beginning of the 6th century A.D. He was court physician at Byzantium. He wrote a large medical work in 16 books, founded on Oribasius and compiled from various sources, especially Galen (Galenos). Eight books of the Greek original were printed in Venice in 1534, and a complete Latin translation by Cornarius at Basel, 1542.

See Weigel, *Aetianarum exercitationum specimen* (1791); Danelius, *Beitrag zur Augenheilkunde des Aetius* (1889); Zernos, *Aetii sermo sextidecimus et ultimus*, editio princeps (1901).

AETNA, a Latin hexameter poem of 644 lines ascribed by the mss. to Virgil. This ascription is now universally rejected, but it is obvious that the author was an imitator of Virgil who was familiar with the Aeneid as well as the Bucolics and Georgics, and therefore lived at least as late as the time of Augustus. As there is no mention of the famous eruption of Vesuvius which destroyed Pompeii and Herculaneum it is safe to presume that the work was composed before A.D. 79. The poem has been attributed by various authorities to Claudian, Cornelius Severus and Manilius, but modern opinion assigns it to Lucilius Junior, the friend of Seneca, whose interest in, and knowledge of scientific matters is alluded to in the philosopher's correspondence. He is known to have been a governor of Sicily and also to have written poems. *Aetna* discusses the possible scientific explanation of the volcano's action.

Text edited (1920) by Robinson Ellis in J. P. Postgate's *Corpus Poetarum Latinorum*.

AETOLIA, a district of northern Greece, bounded on the south by the Corinthian Gulf, on the west by the river Achelous, on the north and east by the western spurs of Parnassus and Oeta. The land naturally falls into two divisions. The basins of the lower Achelous (mod. *Aspropotamo*) and Euenus (*Phidharis*) form a series of alluvial valleys intersected by detached ridges which mostly run parallel to the coast. This district of "Old Aetolia" lacks a suitable sea-board, but the inland, and especially the plain of central Aetolia lying to the north of Lakes Hyria and Trichonis and Mount Aracynthus, forms a rich agricultural country. The northern and eastern regions are broken by an extensive complex of chains and peaks, whose rugged limestone flanks are clad at most with stunted shrubs and barely leave room for a few precarious mule-tracks. These heights often rise in the frontier-ranges of Tymphrestus, Oxia and Corax to more than 7,000 ft.; the snow-capped pinnacle of Kiona attains to 8,240 ft. A few defiles pass through this barrier to the other side of the north Greek watershed.

In early legend Old Aetolia, with its cities of Pleuron and Calydon, figures prominently. During the great migrations (see DORIANS) the population was largely displaced, and the old inhabitants long remained in a backward condition. In the 5th century some tribes were still living in open villages under petty kings, addicted to plunder and piracy, and hardly recognized as Hellenes at all. Yet their military strength was not to be despised: in 426 their archers and slingers easily repelled an Athenian invasion under Demosthenes. In the 4th century the Aetolians began to take a greater part in Greek politics, and, in return for helping Epameinondas (367) and Philip of Macedon (338), recovered control of their sea-board, to which they annexed the Acarnanian coast and the Oeniadae. Aetolia's prosperity dates from the period of Macedonian supremacy. It may be ascribed partly to the wealth and influence acquired by Aetolian mercenaries in Hellenistic courts, but chiefly to the formation of a national Aetolian league, the first effective institution of this kind in Greece. Created originally to meet the peril of an invasion by the Macedonian regents Antipater and Craterus, who had undertaken a punitive expedition against Aetolia after the Lamian War (322), and by Cassander (314-311), the confederacy grew rapidly during the subsequent period of Macedonian weakness. Since 290 it had extended its power over all the uplands of central Greece, where its command over Heracleia (280) provided it with an important defensive position against northern invaders, its control of Delphi and the Amphictyonic council with a useful political instrument. The valour of the Aetolians was conspicuously displayed in 279, when they broke the strength of the Celtic irruption by slaughtering great hordes of marauders. The commemorative festival of the Soteria, which the league established at Delphi, obtained recognition from many leading Greek states. After annexing Boeotia (by 245) the Aetolians controlled all central Greece. Endeavouring next to expand into Peloponnesus, they allied themselves with Antigonus Gonatas of Macedonia against the

Achaean league (q.v.), and besides becoming protectors of Elis and Messenia won several Arcadian cities. Their naval power extended to Cephallonia, to the Aegaeon islands and even to the Hellespont. The league at its zenith had thus a truly imperial status.

Later in the century its power began to be sapped by Macedonia. To check King Demetrius (239-229) the Aetolians joined arms with the Achaeans. In 224 they held Heracleia Trachis against Antigonus Doson, but lost control of Boeotia and Phocis. Since 228 their Arcadian possessions had been abandoned to Sparta. At the same time a new enemy arose in the Illyrian pirate fleets, which outdid them in unscrupulousness and violence. The raids of two Aetolian chiefs in Achaean territory (220) led to a coalition between Achaia and Philip V. of Macedon, who assailed the invaders with great energy, driving them out of Peloponnesus and marching into Aetolia itself, where he surprised and sacked the federal capital Thermon. After buying peace by the cession of Acarnania (217) the league concluded a compact with Rome. In the great war of their Roman allies against Philip the federal troops took a prominent part, their cavalry being largely responsible for the victory of Cynoscephalae (197). The Romans in return restored central Greece to the league, but by withholding its former Thessalian possessions excited its deep resentment. The Aetolians now invited Antiochus III. of Syria to European Greece, and so precipitated a conflict with Rome. But in the war they threw away their chances. In 192 they wasted themselves in an unsuccessful attempt to secure Sparta. In 191 they supported Antiochus badly, and by their slackness in the defence of Thermopylae made his position in Greece untenable. Having thus isolated themselves the Aetolians stood at bay behind their walls against the Romans, who refused all compromises, and, after the general surrender in 189, restricted the league to Aetolia proper and assumed control over its foreign relations. By the time of Sulla, the functions of the Aetolian league had become purely nominal. The federal constitution closely resembled that of the Achaean league (q.v.), for which it doubtless served as a model. The general assembly, convoked every autumn at Thermon to elect officials, and at other places in special emergencies, shaped the league's general policy; it was nominally open to all freemen, though no doubt the Aetolian chieftains really controlled it. The council of deputies from the confederate cities undertook the routine of administration and jurisdiction. The *strategus* (general), aided by 30 *apocleti* (ministers), had complete control in the field and presided over the assembly, though with restricted advisory powers. The Aetolians also used the Amphictyonic synod for passing solemn enactments. The league's relation to outlying dependencies is obscure; many of these were probably mere protectorates or "allied states" and secured no representation. The federal executive was certainly much more efficient than that of the Achaeans, and its councils suffered less from disunion; but its generals and admirals, official or otherwise, enjoyed undue licence; hence the league deservedly gained an evil name for the numerous acts of lawlessness or violence which its troops committed. But as a champion of republican Greece against foreign enemies no other power of the age rendered equal services. In the 15th century Aetolia passed under the rule of Scanderbeg and the Venetians, but was finally conquered for the Turks by Mohammed II. In the War of Independence it was the scene of severe fighting, including the sieges of Missolonghi.

AFARS (DANAKIL), a tribe of African "Arabs" of Hamitic stock. They occupy the arid coast-lands between Abyssinia and the sea. They claim to be Arabs, but are more akin to the Galla and Somali. The tribe is roughly divisible into a pastoral and a

coast-dwelling group. Their religion is chiefly fetich and tree-worship; many, nominally, profess Mohammedanism. They are distinguished by narrow straight noses, thin lips and small pointed chias. They wear, generally, nothing but a waist-cloth. They are divided into many sub-tribes, each having an hereditary sultan.

See Fr. Scaramucci and E. H. Giglioli, *Notizie sui Danakil* (1884); P. Paulitschke, *Ethnographie Nordost-Afrikas* (2 vols., Berlin, 1893-1896), and *Die geographische Erforschung der Adäl-Länder und Harärs in Ost-Afrika* (Leipzig, 1884).

AFER, DOMITIUS, a Roman orator and advocate, was born at Nemausus (Nîmes). He became an informer and gained the favour of Tiberius by accusing Claudia Pulcra, a cousin of Agrippina, of treason. He was consul under Caligula (39) and superintendent of the water supply under Nero. He died in A.D. 60. His pupil, Quintilian, who calls him the greatest orator he had ever known, quotes some of his witty sayings (*dicta*), collections of which were published, and mentions two books by him *On Witnesses*.

See Quintilian, *Instit.* vi. 3. 42, viii. 5. 16, x. 1. 118, etc.; Tac. *Ann.* iv. 52, 68, xiv. 19; Dio Cassius *lxx.* 19, *lxx.* 33; Pliny, *Epp.* ii. 14, viii. 18.

AFFECTION, literally, a state resulting generally from an external influence. The term was at one time employed to denote the states even of material bodies, but is now confined to certain mental states only, in fact, to certain feelings. It is popularly used of a sentiment between persons amounting to more than good will or friendship. By ethical writers the word has been used generally of distinct states of feeling, both lasting and spasmodic; some contrast it with "passion," as being free from the distinctively sensual element. More specifically the word has been restricted to emotional states which are in relation to persons. In the former sense, it is the Gr. *πάθος*, and as such it appears in Descartes and most of the early British ethical writers. On various grounds, however—e.g., that it does not involve anxiety or excitement, that it is comparatively inert and compatible with the entire absence of the sensuous element—it is generally and usefully distinguished from passion. In this narrower sense the word has played a great part in ethical systems, which have spoken of the social or parental "affections" as in some sense a part of moral obligation. For a consideration of these and similar problems, which depend ultimately on the degree in which the affections are regarded as voluntary, see H. Sidgwick, *Methods of Ethics*, pp. 345-349.

In psychology the terms "affection" and "affective" are used for the characteristic quality of experiences that are neither cognitive nor conational. As all intellectual phenomena have by some psychologists been reduced to sensation, so all feeling has been regarded as reducible to simple mental affection, the element of which all emotional manifestations are ultimately composed. The nature of this element is a problem which has been provisionally, but not conclusively, solved by many psychologists; the method is necessarily experimental, and all experiments on feeling are peculiarly difficult. The solutions proposed are two. In the first, all affective phenomena are primarily divisible into those which are pleasurable and those which are the reverse. The main objections to this are that it does not explain the infinite variety of phenomena, and that it disregards the distinction which most philosophers admit between higher and lower pleasures. The second solution is that every sensation has its specific affective quality, though by reason of the poverty of language many of these have no name. W. Wundt, *Outlines of Psychology* (trans. C. H. Judd, Leipzig, 1897), maintains that we may group under three main affective directions, each with its negative, all the infinite varieties in question; these are (a) pleasure, or rather pleasantness, and the reverse, (b) tension and relaxation, (c) excitement and depression.

Two methods of experiment have been tried. The first, introduced by A. Mosso, the Italian psychologist, consists in recording the physical phenomena which are observed to accompany modifications of the affective consciousness. Thus it is found that the action of the heart is accelerated by pleasant, and retarded by unpleasant, stimuli; again, changes of weight are found to accompany modifications of affection—and so on.

The second is Fechner's method; it consists in recording the changes in feeling-tone produced in a subject by bringing him in contact with a series of conditions, objects or stimuli graduated according to a scientific plan and presented singly, in pairs or in groups. The result is a comparative table of likes and dislikes.

(See FEELING.)

AFFETTUOSO (Ital.), a musical direction signifying that the composition or particular passage so marked is to be played with much expression and feeling. *Espressivo* and *con espressione* are other terms having much the same significance.

AFFIDAVIT, a written statement sworn or affirmed to before some person who has authority to administer an oath or affirmation. Evidence is chiefly taken by means of affidavits in the chancery division of the High Court of Justice in England on a petition, summons or motion. Interlocutory proceedings before trial are conducted by affidavits, e.g., for discovery of documents, hence called *affidavit of documents*. Affidavits are sometimes necessary as proof that certain legal formalities have been duly and legally performed. On special application to the court a deponent may be cross-examined on the statements contained in his affidavit. In Scotland the testimony of witnesses by affidavit is almost unknown, except in proceedings in the Sheriff Court of Chancery, and petitions for the sequestration of bankruptcy, where affidavits are enjoined by statute. In the rules of the Supreme Court (R.S.C. Ord. XXXVIII.) certain formal requirements are laid down for all affidavits and affirmations in causes or matters depending in the High Court. An affidavit must consist of title, body or statement and jurat. It must be written or printed on foolscap, bookwise, in the first person; give correctly the names of the parties to the action; and the description and true place of abode of the deponent. An affidavit is confined, except on interlocutory motions, to such facts as the witness is able of his own knowledge to prove. The signature of the deponent must be written opposite to the jurat, which must contain the place, date and time of swearing, and this signed by the officer or magistrate before whom the affidavit is sworn. An affidavit sworn on a Sunday is not invalid. Quakers, Moravians and Separatists were first privileged to make a solemn declaration or affirmation, and by the Common Law Procedure Act, 1852, and other statutes all persons prevented by religious belief from taking an oath were allowed to affirm; and, finally, by the Oaths Act, 1888, every person who objects to be sworn is allowed to affirm in all places and for all purposes where an oath is required by law. By an act of 1835 justices are permitted to take affidavits in any matter by declaration, and a person making a false affidavit in this way is liable to punishment. The same act prohibited justices of peace from administering oaths in any matter in which they had not jurisdiction as judges, except when an oath was specially authorized by statute, as in the bankruptcy law, and excepting criminal inquiries, parliamentary proceedings and instances where oaths are required to give validity to documents abroad. Scottish justices can act in England and *vice versa*. The Oaths Act, 1888, and the Commissioner of Oaths Act, 1889, consolidated all previous enactments relating to oaths and gave the lord chancellor power to appoint commissioners for oaths to take affidavits for all purposes (see OATH).

In the United States affidavit has the same meaning as in England and its general uses are the same, but it is not substituted for oral evidence in court to anything like the extent to which that is done in the English courts of chancery. The statutes of each State designate the persons before whom affidavits may be made outside the State, and special commissioners are appointed for that purpose by each State. Affidavits made abroad must be made before such commissioners or persons so designated, who are usually diplomatic and consular officials, justices, notaries public or mayors.

AFFILIATION, in law, the procedure by which the paternity of a bastard child is determined, and the obligation of contributing to its support enforced. In England a number of statutes on the subject have been passed, the chief being the Bastardy Act of 1845, the Bastardy Laws Amendment Acts of 1872 and 1873, the

Affiliation Orders Act, 1914, the Affiliation Orders Act, 1918, and the Bastardy Act, 1923. The mother of a bastard may summon the putative father to petty sessions within 12 months of the birth (or at any later time if he is proved to have contributed to the child's support or ceased to reside in England within 12 months after the birth), and the justices, after hearing evidence on both sides, may, if the mother's evidence be corroborated in some material particular, adjudge the man to be the putative father of the child, and order him to pay a sum not exceeding 20 shillings a week for its maintenance, together with a sum for expenses incidental to the birth, or the funeral expenses, if it has died before the date of order, and the costs of the proceedings. An order ceases to be valid after the child reaches the age of 13, except as regards arrears, but the justices may in the order direct the payments to be continued until the child is 16 years of age. An appeal to quarter sessions is open to both the mother and the defendant, and a further appeal on questions of law to the King's Bench. Should the child afterwards become chargeable to the parish, the sum due by the father may be received by the relieving officer. When a bastard child whose mother has not obtained an order, becomes chargeable to the parish, the guardians may proceed against the putative father for a contribution, and such an order may be varied and continued in favour of the mother or person having custody of the child. Any woman who is single, a widow, or a married woman living apart from her husband, may make an application for a summons. The Bastardy Act, 1872, makes due provision for the enforcement of an order of affiliation, and commitment is governed by the Summary Jurisdiction Act, 1879, and the Criminal Justice Act, 1914. In the case of soldiers an affiliation order cannot be enforced in the usual way, but by the Army Act 1881, as amended in 1883, 1891, 1904 and 1915, if an order has been made against a soldier of the regular forces, a portion of the soldier's pay may be retained. There is similar legislation with regard to sailors in the Royal Navy, by the Naval Discipline Act, 1915.

It having been found in practice that affiliation orders became ineffective owing to the unwillingness or inability of the mother to make continual appearances before the justices, under the Affiliation Orders Act, 1914, collecting officers may be appointed.

In the United States the father is primarily responsible for the support of a bastard child. The mother is responsible in the event of the father's death.

In the British colonies there is some procedure (usually termed filiation) akin to that described above, by means of which a mother can obtain a contribution to the support of her illegitimate child from the putative father. On the continent of Europe, however, the legislation of the various countries differs rather widely. (See ADOPTION; also BASTARD; POOR LAWS.)

AFFINE GEOMETRY. An affine geometry, as distinguished from a projective geometry, involves a definition of parallelism. Thus, when from the definitions and theorems of the ordinary euclidean geometry of the plane all those involving euclidean measurement of length and angle are eliminated, the residue is an affine geometry. In this case the line at infinity is unique, in that any two lines meeting in a point of the former are parallel. In the projective geometry of the plane there is no such preferred line; when any line is designated as preferred in this sense, we have a corresponding affine geometry. For example, in affine geometry there is a distinction between an ellipse, a parabola and a hyperbola, but not in projective geometry; moreover, only when the geometry is metrical is there a distinction between circles and ellipses.

The euclidean affine geometry is given analytic form by means of coordinates x and y referred to two intersecting lines of the plane in the usual manner. In this case the equations

$$\begin{aligned} x_1 &= a_{11}x + a_{12}y + a_1, \\ y_1 &= a_{21}x + a_{22}y + a_2, \end{aligned} \quad (1)$$

where the a 's are arbitrary constants subject to the condition

$a_{11}a_{22} - a_{12}a_{21} \neq 0$, define the most general transformation of points of the plane among themselves which transforms parallel lines into parallel lines. Such a transformation is called *affine*. The transformations (1) form a group, and we may say, following Klein, that the body of definitions and theorems expressing properties of quantities invariant under this group is an affine geometry. If $x', y', x'', y'', x''', y'''$ are the coordinates of three non-collinear points, the quantity

$$\begin{vmatrix} x' & y' & 1 \\ x'' & y'' & 1 \\ x''' & y''' & 1 \end{vmatrix} \quad (2)$$

is invariant under transformations (1) for which $a_{11}a_{22} - a_{12}a_{21} = 1$. These transformations are called *equiaffine*. There is a considerable body of theorems concerning properties of plane curves which remain invariant under equiaffine transformations. In particular, there is a metric theory based upon a certain invariant of the type (2) associated with a curve.

The foregoing concepts are readily generalized to spaces of higher order. Thus there is for spaces of three dimensions a theory of curves and surfaces analogous in many respects to the theory for euclidean space of three dimensions. The developments of these ideas have been made by many geometers, notably Klein, Möbius, Sylvester and lately by Blaschke and Pick.

Any n independent variables x_i , where i takes the values 1 to n , may be thought of as the coordinates of a general n -dimensional space, or variety, in the sense that each set of values of the x 's defines a point. In a space thus defined there is not a basis for the comparison of directions at different points. Such a basis is provided when a definition of parallelism is added. In Riemannian geometry we say, following Levi-Civita, that at points of a curve, defined by $x_i = f_i(t)$, ($i = 1, \dots, n$), a set of functions ξ^i of t satisfying the system of equations

$$\begin{aligned} \xi^i \left(\frac{d\xi^j}{dt} + \sum_{k,l} \Gamma_{kl}^j \xi^k \frac{dx_l}{dt} \right) \\ - \xi^j \left(\frac{d\xi^i}{dt} + \sum_{k,l} \Gamma_{kl}^i \xi^k \frac{dx_l}{dt} \right) = 0 \quad (i, j = 1, \dots, n) \end{aligned} \quad (3)$$

are the components of a family of vectors parallel with respect to the curve; in this case Γ_{jk}^i are functions of the x 's determined by the metric of the space (see RIEMANNIAN GEOMETRY). As thus defined, parallelism is relative to a curve, and not absolute, as in euclidean space. If the Γ 's in (3) are taken as n^2 arbitrary functions of the x 's, equations (3) may be taken as the definition of parallelism for a general V_n , thus generalizing Levi-Civita's concept of parallelism for spaces with a Riemannian metric. In this case we say that the space is *affinely connected*, following Weyl; the Γ 's are called the coefficients of the affine connection.

When $\Gamma_{jk}^i = \Gamma_{kj}^i$, the connection is called *symmetric*, otherwise *asymmetric*. When, and only when, the connection is symmetric, there exist preferred coordinate systems, with a given point as origin, with respect to which corresponding components of a vector at the given point and of a parallel one at a nearby point are the same. When the connection is asymmetric, there are other connections giving an equivalent definition of parallelism; the definition is unique for symmetric connections.

The fundamental curves of an affinely connected space are those whose tangents are parallel with respect to the curves; i.e., they are the straight lines of the space. They are the integral curves of the differential equations obtained when $\xi^i = dx_i/dt$ in (3). Some writers call them the *paths* of the space, others *geodesics*, since they are the generalizations of the geodesics of Riemannian spaces. There are many affine connections with the same paths, so that the theorems dealing with the paths and not with a particular affine connection constitute a projective geometry. A theory of affinely connected spaces, in many respects analogous to Riemannian geometry, has been developed recently, notably by Cartan, Eddington, Einstein, Schouten, Joseph M. Thomas, Tracy Y. Thomas, Veblen and Weyl.

AFFINITY, in law, as distinguished from consanguinity (*q.v.*), the term applied to the relation which each party to a marriage, the husband and wife, bears to the kindred of the other. Affinity is usually described as of three kinds: (1) *direct*, that relationship which subsists between the husband and his wife's relations by blood or between the wife and the husband's relations by blood. The marriage having made them one person, the blood relations of each are held as related by affinity in the same degree to the one spouse as by consanguinity to the other. But the relation is only with the married parties themselves, and does not bring those in affinity with them in affinity with each other; so a wife's sister has no affinity to her husband's brother. This is (2) *secondary* affinity. (3) *Collateral* affinity is the relationship subsisting between the husband and the relations of his wife's relations. (See CONSANGUINITY; MARRIAGE.)

AFFINITY, CHEMICAL, the property or relation in virtue of which substances are capable of entering into chemical combination with each other. (See CHEMISTRY; CHEMICAL ACTION; VALENCY.)

AFFIRMATION, the declaration that something is true; in logic, a positive judgment, the union of the subject and predicate of a proposition; particularly, in law, the solemn declaration allowed to those who conscientiously object to taking an oath.

AFFORESTATION: see FORESTS AND FORESTRY.

AFFRAY is the misdemeanour of breaking the peace in public to the terror of the king's subjects. Fighting in public is an affray, but no actual violence is necessary, and the offence is committed even where a man arms himself with weapons so as to cause terror to the public. Abusive and threatening words alone will not amount to an affray. In 1903 at the Carnarvon assizes before Mr. Justice Wills a conviction was obtained in *Rex v. Meade* where the accused went about armed and discharged a loaded revolver in a public street. He was also indicted under a statute of 1328 (2 Edw. III. c. 3). (See also RIOT.)

In the United States the English common law as to affray applies, subject to certain modifications by the statutes of particular States (Bishop, *Amer. Crim. Law*, 9th ed., 1923, vol. i. § 535). The Indian penal code (§159) adopts the English definition of affray, with the substitution of "actual disturbance of the peace" for "causing terror to the lieges."

AFFRE, DENIS AUGUSTE (1793-1848), archbishop of Paris, was born at Saint-Rome-de-Tarn, on Sept. 27 1793. He became archbishop of Paris in 1840. His episcopate is chiefly remembered for its tragic close. During the riots of June 23-26, 1848, the archbishop mounted a barricade in the Faubourg St. Antoine and was hit by a stray bullet.

AFFREIGHTMENT. Payment for the carriage of goods by water, more especially by sea, is called freight, and a bargain made between the carrier and the person whose goods are to be so carried is called a contract of affreightment. The law does not require that a contract of this kind shall be made in writing, but usually it is expressed in that form. The terms on which goods are carried by sea are, except in coasting trade, ordinarily expressed in a charter-party or a bill of lading or both. The former may be shortly described as a contract between a shipowner and a merchant for the hire or use of a ship, and the latter as a receipt for goods, stating the terms on which they are delivered to and received by a ship. A charter-party usually relates to the full cargo of a ship, and a bill of lading may do the same, but it is more often given with reference to a particular parcel of goods.

Terms Implied by Law.—The parties to a contract of affreightment are assumed by law (unless the contract expressly negatives or qualifies the assumption) to have dealt with each other on the footing of certain obligations included among the terms of contract. In the unusual case of no terms being expressly agreed, the implied terms alone would regulate the relations of the parties. In the common case of terms being expressly agreed, the

implied terms are included, subject to any modification of them specifically and explicitly made by the express terms. It should be mentioned in passing that, where the goods are carried under bills of lading, certain terms are by statute (as explained below) included in the contract which the parties are not free to exclude even if they wish.

Subject then to any modification made by the contract, a person who for payment carries goods by sea is under an implied obligation to exercise due care and diligence. Except possibly in a case where the sea carrier is not a common carrier (*i.e.*, where he does not profess himself ready to carry goods for everybody) he has a further degree of responsibility, in that he is liable for every accident, unless caused by act of God, or of the king's enemies, or by inherent defect of the goods themselves, or by their having been sacrificed for the general safety. He also impliedly undertakes absolutely that the ship is seaworthy at the beginning of the voyage, and that he will proceed on the voyage with reasonable dispatch, and without unnecessary deviation. Seaworthy has a special meaning as explained later. The carrier may in some circumstances be entitled to claim statutory limitation of the amount of his liability.

On the part of the shipper an undertaking is implied not to ship dangerous goods without notice, and he or the person entitled to take delivery of the goods is impliedly under obligation (1) to be prepared, without notice from the carrier, to take delivery within a reasonable time after the arrival of the ship at the place of delivery, and (2) to pay freight and general average contribution (if any) before he can claim delivery of the goods. In some circumstances where performance of the contract becomes impossible the parties may be released from performance under terms deemed to be implied in the contract.

Parties to the Contract.—As already mentioned, the terms of contract are ordinarily expressed in a charter-party (shortly, a charter) or a bill of lading, or both. A bill of lading may be more fully described as "a receipt for goods shipped on board a ship, signed by the person who contracts to carry them, or his agent, and stating the terms on which the goods were delivered to and received by the ship. It is not the contract, for that has been made before the bill of lading was signed and delivered, but it is excellent evidence of the terms of the contract" (Scrutton). Usually the printed form of the particular carrier is filled up in writing and signed by the captain, broker or other agent of the carrier, and the terms of the contract made or deemed to have been made before the bill of lading was given are thus reduced to documentary form. Though in form a receipt, a bill of lading is also a transferable document of title representing the goods to which it relates.

Where the contract is between a shipper and a carrier who is himself the shipowner the bill of lading binds the shipowner. In the case of a chartered ship—*i.e.*, a ship hired by a charterer—the bill of lading may, according to the circumstances, bind the shipowner or the charterer. Charters are varied in form. Under some, where the shipowner parts with the whole possession and control of the ship (so that the charter amounts to a demise, a form rare in modern practice) the contract would be between the shipper and the charterer. Under other charters the charterer may merely undertake that a full cargo shall be shipped and guarantee payment of a certain freight. There the contract would be between shipper and shipowner. Where, in intermediate cases, the shipper is a person other than the charterer, the bill of lading may, according to the terms of the charter, bind the shipowner or the charterer.

Charter-parties.—Charters (apart from the unusual form amounting to a demise of the ship) are entered into for a voyage (or series of voyages) or for a period of time. A voyage charter commonly provides that the ship, as described, shall proceed to a named place, and there load a cargo, and shall then proceed to a named place of discharge, where the cargo is to be delivered. Freight is to be paid in a lump sum, or at a rate named on the cargo carried, or calculated in some other way. The number of days within which the charterers are to load and discharge (called lay days) is specified, and also a rate for demurrage

should the ship be longer detained; with provisions to apply in the event of stoppages occurring. "Days" in a charter is understood to mean calendar days of 24 hours commencing at midnight. Sundays and holidays are included unless expressly excepted. "Working days" means all days on which work is ordinarily done at the port, excluding Sundays and holidays. Provisions as to time are frequently expressed in hours instead of days. Further clauses deal with issue of bills of lading, exceptions from liability, discharge of cargo, payment of freight, general average, ceasing of charterer's liability, brokerage, etc.

By a time charter the ship is hired to the charterers for a specified time, commencing on a certain date, when the ship is to be placed at the disposal of the charterers, at some specified place, or place to be named, to be employed in lawful trades between certain limits. The clauses deal with various matters in connection with the employment of the ship, such as payments for stores, provisions, wages, insurance, fuel, port and other charges, the appointment and giving of directions to the master of the ship, stevedoring, exceptions from shipowner's liability, arbitration, etc. A number of common forms of charter are in use containing clauses adjusted to the requirements and conditions of particular trades.

In determining the effect to be given to a charter it may be necessary to take into consideration along with its express terms other terms which, as already explained, are implied by law. Thus if a charter contains no express provision as to seaworthiness there is underlying the contract, and implied and involved in it, a warranty by the shipowner that the ship is seaworthy. The special meaning attached to this word is that the ship shall have that degree of fitness which an ordinarily careful and prudent owner would require his ship to have at the commencement of her voyage, having regard to all the probable circumstances of it. Not only must the ship be tight, staunch and strong, but also fit for the carriage of the particular kind of cargo to be carried. This implied absolute warranty of seaworthiness is fulfilled if the ship is seaworthy when she leaves her moorings, and does not include any undertaking that the ship shall continue seaworthy; but where the voyage is in stages the ship must be fit for each stage when entered upon.

There may also have to be taken into consideration, in construing a charter, trade usages or customs with reference to which the parties are presumed to have made their contract. The express terms often refer to custom (which in a charter means a settled and established practice of the port) and they may be explained by evidence of usage or custom short of alleging anything inconsistent with them. For example, stipulations as to loading or discharging cargo in a port may be thus construed. Evidence of custom may be given to explain the meaning of working day at the port.

When a ship has reached the place where (under a voyage charter) she is to be ready to load, and is ready to load, and the charterers have been notified of this, the ship is an arrived ship and the lay days (for loading) begin to run.

Subject to any express or implied qualification, a charterer undertakes absolutely to furnish a cargo. When he fails to furnish a full cargo the damages which the shipowner is entitled to recover for this breach of contract are called dead freight. It is the duty of the master of the ship on behalf of the owner to receive and properly stow on board the cargo to be carried, which ordinarily is to be delivered to him alongside, but this duty may be subject to modification by custom or contract.

Should a ship be detained beyond the lay days the charterer will become liable to pay for the detention. If the basis for payment has been agreed by the charter the payment is known as demurrage. If it has not been agreed or if the charter refers to a fixed number of demurrage days which has been exceeded, then the payment, or part of it, will be damages for detention, the rate of which may have to be ascertained and may be different from the demurrage rate.

A common provision in a charter is the cesser clause, which is to the effect that the charterer's liability shall cease on the shipment of the cargo to the extent to which the charter gives

the shipowner a lien. Under common law the shipowner's lien on the cargo is in respect only of freight and general average contributions. The cesser clause ordinarily confirms this, and gives a lien for demurrage, and sometimes also for dead freight.

Bills of Lading.—Though either a charter or a bill of lading or both together may express the terms of a contract, the transactions in which no bill of lading is issued are few, because the bill of lading, in addition to its primary purpose of expressing terms of contract, serves in commerce as a transferable document of title representing the goods to which it relates. Where the charterer is also the shipper, the bill of lading, as between shipowner and charterer, is regarded as no more than a receipt which does not alter the contract contained in the charter. It is merely a receipt until used by the charterer as a transferable document of title, *i.e.*, until negotiated. Where the shipper is a person other than the charterer, the bill of lading is the evidence of the contract and does not, except by plain words, incorporate or impose on the shipper the obligations of the charter. Where the shipper (whether he is the charterer or not) has indorsed the bill of lading to a holder for value, the bill of lading is the only evidence of the contract.

Apart from statutory limitations on freedom of contract presently to be referred to, a common form of bill of lading (as set out in Carver, *Carriage of Goods by Sea*), was as follows:—

"Shipped, in good order and condition, by
in and upon the good ship called the
whereof is master for this present voyage,
now riding at anchor in the port of and
bound for (description of goods) marked
and numbered as in the margin, and are to be delivered in the
like good order and condition at aforesaid (the
act of God, the king's enemies, fire, and all and every other dangers
and accidents of the seas, rivers, and navigation of whatever
nature and kind soever excepted), unto or
to his assigns, he or they paying freight for the said goods at the
rate of with primage and average accustomed.
In witness whereof, the master or agent of the said ship hath
affirmed to bills of lading, all of this tenor and date,
the one of which bills being accomplished the others to stand void.
"Dated in the day
of
"(Signed)"

Many "negligence clauses" (exceptions from liability formerly inserted to protect sea carriers) have disappeared from bills of lading as a result of legislation. In the United States the Harter Act was passed in 1893. It requires the exercise of due diligence properly to equip the ship and make it seaworthy, and, subject to this being done, gives exemption from navigation risks as distinguished from carrier's risks which the act compulsorily imposes on the carrier by prohibiting the insertion in any bill of lading or shipping document of any clause whereby obligations carefully to handle and stow the cargo and to care for and deliver the same may be lessened, weakened or avoided. Similar legislation was afterwards passed by some of the British dominions.

More recent legislation has attempted to define by its express terms the liabilities as well as the immunities of the carrier. The Carriage of Goods by Sea Act, 1924, was formulated in this way. Scheduled to it is a series of rules which are in effect standard clauses to be deemed part of the terms of bills of lading. This act is applicable to these documents when issued in Great Britain or Northern Ireland. Similar legislation has been passed in Australia, India, most of the British colonies and Belgium.

The Carriage of Goods by Sea Act requires that (subject to limited exceptions) the bill of lading shall expressly incorporate as part of its terms the provisions of the rules scheduled to the act. These impose on the carrier an irreducible minimum of responsibility for the safe carriage of the goods.

Though the Act thus defines the carrier's liabilities, it does not (except in the case of the implied absolute undertaking to provide a seaworthy ship) expressly exclude the implied obligations referred to above. Though an alternative basis of liability is

expressly laid down, the question apparently might arise whether those obligations (other than that of seaworthiness) still exist underlying the contract and implied and involved in it. In any event the compulsory minimum of responsibility is a protection to third persons (such as endorsees) who, though not parties to the contract, may be affected by it, as well as to shippers.

As the rules scheduled to the act become part of the terms of British and Belgian bills of lading they are important, but it is not practicable to give here more than a summary.

Under the definitions in Article I "Goods" includes articles of every kind except live animals and deck cargo and "carriage of goods" covers the period from the time when the goods are loaded on to the time when they are discharged from the ship.

By Article II the carrier is subject to the responsibilities and liabilities, and entitled to the rights set forth in the rules.

The carrier's responsibilities and liabilities detailed in Article III are to exercise due diligence to (1) make the ship seaworthy, (2) properly man, equip and supply the ship, (3) make the holds fit and safe for goods. He must also properly and carefully load, handle, stow, carry, keep, care for and discharge the goods, and issue a bill of lading showing certain particulars of quantity and condition of goods. This document becomes *prima facie* evidence of receipt by the carrier of the goods as therein described. Unless notice of loss or damage is given on delivery (or, if not apparent, within three days) delivery is *prima facie* evidence of delivery and, in any event, carrier is discharged from all liability unless suit is brought within one year. Nothing may be added lessening carrier's liability, but clauses increasing it are allowable, e.g., clause making bill of lading *conclusive* evidence of shipment.

Article IV relieves the carrier from liability for loss or damage resulting from (1) unseaworthiness, unless caused by want of due diligence, (2) a number of specified perils (e.g., act or neglect of the servants of the carrier in the navigation or in the management of the ship, fire, perils of the sea, act of God, etc.) which are mostly perils arising without the actual fault or privity of the carrier. Reasonable deviation is allowed. The carrier is not liable for loss or damage to goods in an amount exceeding £100 per package or unit unless value is declared before shipment and inserted in bill of lading.

Under the form of bill of lading set out above the goods are to be delivered to a named person "or to his assigns." A document in this form is by English law a negotiable instrument, in the sense that it is transferable by indorsement and delivery. A bill of lading may be indorsed by the person named in it (the shipper or the consignee) either in blank, by a simple signature on the back, or specially by indorsing and signing a direction to deliver to some other person or order. The indorsee may then transfer by indorsing in blank or specially. If indorsed in blank, or made out to a name left blank, or to bearer, a bill may be dealt with by mere delivery.

The indorsement and delivery of a bill of lading transfers such property as it was the intention of the parties to the indorsement to transfer, and, by the Bills of Lading Act, 1855, also transfers to the indorsee, to whom the property in the goods passes, the rights and liabilities of the shipper under the bill of lading. A pledgee is however not an indorsee to whom the property passes, and does not incur liabilities unless he takes delivery of the goods.

Performance of the Contract.—Reference has already been made to the implied undertakings by the carrier that he will proceed on the voyage with reasonable dispatch and without unnecessary deviation, and to the doubt whether these obligations still underlie the contract where a bill of lading has been issued subject to the statutory rules.

To complete the voyage the sea carrier should, if necessary, repair the ship, or tranship the cargo in order that it may be forwarded to its destination.

If necessary for the common safety a shipmaster may jettison cargo properly stowed. Any such extraordinary sacrifice or expenditure intentionally and reasonably made or incurred for the common safety, for the purpose of preserving from peril the property involved in a common maritime adventure, is a general average act. Damages, losses and expenses which are the direct

consequence of a general average act are borne by ship, freight and cargo as contributing interests. The contributions are adjusted by a general average statement. If, as is commonly the case, the charter or bill of lading incorporates by reference the York-Antwerp Rules, 1924, the adjustment is made as provided by those rules. (See further as to this under AVERAGE.)

Should the contract prove impossible of performance owing to circumstances which were unforeseen, and to which no provision in the contract is applicable (in particular where circumstances arise from the occurrence of war or in some other way, involving such delay as to frustrate the commercial purpose of the adventure) the contract may be held by the court to have come to an end by virtue of a provision implied in it. Cases of this kind are, of course, quite different from those where the contract, when made, cannot be performed without breaking the law. It is then void from the beginning for illegality.

Under the contract the ship is bound to proceed (unless prevented by an excepted peril) to the agreed place of discharge. On the ship's arrival there the charterer or consignee is bound to take delivery. Unless, under express provision, or by custom, notice of arrival is to be given, none is required. In the case of goods imported from abroad into Great Britain, if the owner of the goods fails to make entry of them at the Customs, or to take delivery, the goods may, under and subject to compliance with the provisions of the Merchant Shipping Act, 1894, sections 492-501, be landed and warehoused. Delivery should not be made except to a person producing a bill of lading making the goods deliverable to that person. By custom bills of lading are made out in sets, usually of three copies, but the carrier is justified in delivering to the first person producing a bill of lading making the goods deliverable to him, if without notice or knowledge of anything making it wrong to do so.

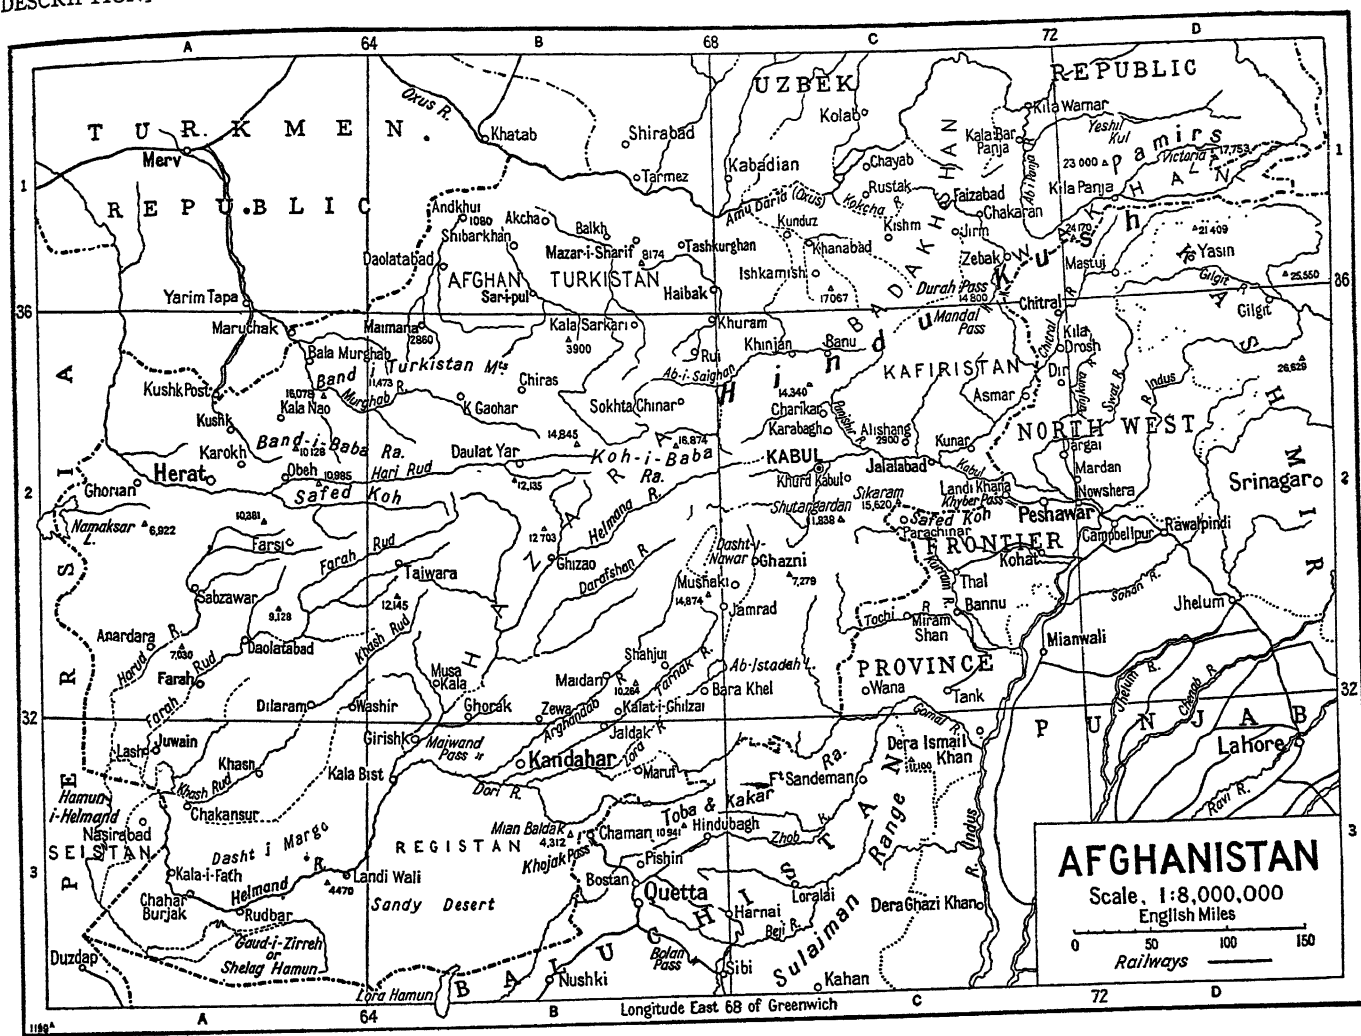

If goods are carried to the place where the voyage is to end, and, though damaged, are in a merchantable condition and ready for delivery, freight is payable. For delivery short of destination no freight is due unless the parties have taken steps justifying the conclusion that they intended to make a fresh contract whereby the owner of the goods has agreed to accept the goods at an intermediate port. English law in this respect differs from some continental laws under which proportional distance freight is payable. For short delivery at destination pro rata freight is payable. The carrier is entitled to a lien for freight payable on delivery. This is a possessory lien entitling him to withhold delivery until payment. It extends also to a general average contribution and to expenses incurred in the protection and preservation of the goods. If expressly so provided by the contract, the lien may extend to other matters, e.g., demurrage, damages for detention and dead freight.

See T. G. Carver, *Carriage of Goods by Sea* (1925); T. E. Scrutton, *Charter-parties and Bills of Lading* (1925). (S. D. C.)

AFFRETANDO (Ital.), a musical term having just the same significance as *accelerando*, i.e., a quickening of the tempo or speed, but with a suggestion of hurry and agitation in addition.

AFGHANISTAN, a country of Asia. Estimated area is 245,000-270,000 sq. m. (including Badakshan and Kafiristan). Pop. about 8,000,000. It is bounded on the north by Russian Turkistan, on the west by Persia, and on the east and south by Kashmir and the north-west frontier of India and Baluchistan. Surveys from 1872 to 1905 delimited the frontier which was accepted by Afghanistan in a treaty of 1921.

Boundaries.—From the town of Zulfikar on the Hari Rud river the boundary between Afghanistan and Russia is roughly parallel to the Paropamisus, and about 35 m. N. of it, till it strikes the Kushk river in Jamshidi territory at a point once known as Chahil Dukteran, but now the Russian post Kushkinski, terminus of a branch railway from Merv. Kushkinski is about 20 m. below the old Jamshidi settlement of Kushk, the capital of Badghis. From Kushkinski the boundary runs north-east, crossing the Murghab river near Maruchak (an Afghan fortress), and passing through the hills of the Chul, and the undulating deserts of the Aleli Turkmans, to the Oxus, leaving the valleys of Charshamba and of Andkhui (to which it runs approximately parallel) within Afghan

JOHN BARTHOLOMEW & SON, LTD., EDINBURGH

THE LAND OF THE AFGHANS HAS BEEN SUCCESSIVELY, IN ITS LONG AND INTERESTING HISTORY, A CONGERIES OF PETTY STATES, THE CENTRE OF GREAT EMPIRES RULED BY FOREIGNERS AND A DISMEMBERED COUNTRY, FURNISHING PROVINCES TO THREE MONARCHIES. IT IS NOW A DISTINCT POLITICAL ENTITY RULED BY AN INDEPENDENT NATIVE SOVEREIGN, THE AMIR. AS A COUNTRY FROM WHICH THE KHYBER PASS GIVES ADMISSION TO INDIA, AFGHANISTAN HAS ALWAYS POSSESSED A STRATEGIC IMPORTANCE IN EASTERN AFFAIRS

limits. These valleys define the limits of cultivation in this direction. Throughout this region the boundary is generally marked by pillars, but here and there local water-partings or watercourses are used. The boundary meets the Oxus at Khamiab at the western extremity of the cultivated district of Khwaja Salar and from that point to the eastern end of Lake Victoria in the Pamirs the main channel of the Oxus river forms the northern limit of Afghanistan. (See Oxus.) Eastwards from Lake Victoria the frontier was determined by the Pamir Boundary Commission (1895). A part of the little Pamir is Afghan, but the boundary crosses this Pamir before the great bend northwards of the Aksu takes place, and passing over a series of crags and untraversable mountain ridges, is lost on the Chinese frontier in the snowfields of Sarikol. Bending back westwards the frontier now follows the water-parting of the Hindu Kush; and as the Hindu Kush absolutely overhangs the Oxus nearly opposite Ishkashim, it follows that, at this point, Afghanistan is about 100 m. wide. Thus a small high portion of the State extends eastwards from its north-eastern corner and is attached to the great Afghan quadrilateral by the thin link of the Panja valley. These narrow limits (called Wakhan) include the lofty spurs of the northern flank of the Hindu Kush, an impassable barrier at this point, where the glacial passes reach 19,000 ft. in altitude, and the enclosing peaks 24,000 ft. The backbone or main water-divide of the Hindu Kush continues to form the boundary between Afghanistan and the North-West Frontier Province of India until it reaches Kafiristan. From near the Dorah pass (14,800 ft.), which connects Chitral with the Panja

(or Oxus) river, a long, straight, snow-clad spur reaches southwards, which divides the Kafiristan valley of Bashgol from that of Chitral, and this continues to define the eastern limits of Afghanistan till it nearly touches the Chitral river opposite the village of Arnawai, 45 m. south of Chitral. Here the Bashgol and Chitral valleys unite and the boundary passes to the water-divide east of the Chitral river; along this water-divide it extends to a point nearly opposite the quaint old town of Pashat in the Kunar valley (the Chitral river has become the Kunar in its course southwards), and then divides the Mohmand country till it strikes the Kabul river near Palosi. Thence following a course nearly due south it reaches Landi Kotal. From the abutment of the Hindu Kush on the Sarikol in the Pamir region to Landi Kotal, and throughout its eastern and southern limits, the boundary of Afghanistan touches districts which were brought under British political control with the formation of the North-West Frontier Province of India in 1901. From the neighbourhood of Landi Kotal the boundary is carried to the Safed Koh overlooking the Afridi Tirah, and then, rounding off the cultivated portions of the Kurram valley below the Peiwar, it crosses the Kaitu and passes to the upper reaches of the Tochi. Crossing these again, it is continued on the west of Waziristan, finally striking the Gomal river at Domandi. South of the Gomal it separates Afghanistan from Baluchistan, which here adjoins the North-West Frontier Province. From Domandi (the junction of the Kunder river with the Gomal) the Afghan boundary marches with that of Baluchistan. (See BALUCHISTAN.) It is carried south-west mainly along the Kunder and

Kadanai to a point beyond the Sind-Peshin terminal station of New Chaman, west of the Khojak range, and then drops south to Shorawak and Nushki. From Nushki it crosses the Helmand desert, touching the crest of a well-defined watershed for a great part of the way and, leaving Chagai to Baluchistan, it strikes nearly west to the Persian frontier, and joins it on the Koh-i-Malik Siah mountain, south of Seistan.

Indefinite Limits.—Two important points upon this part of the Afghan boundary are notable. It leaves some of the most fanatical of the Durani Afghan people on the Baluch side of the frontier in the Toba district, north of the Quetta-Chaman line of railway; and it passes 50m. S. of the Helmand river, enclosing within Afghanistan the only approach to Seistan from India which is available during the seasons of Helmand overflow. Beyond these lagoons to Hashtadan it is still indefinite. The eastern limits of Hashtadan had been previously fixed as far north as the Hari Rud river at Toman Agha. From this point to Zulfikar the Hari Rud is itself the boundary. The Hindu Kush spreads fan-wise from a stem of great height (24,000ft.) in the north-east. The rays of the fan diminish in height to the north and south of a more or less central one called Koh-i-Baba, west of Kabul (greatest height 16,870ft.) and the Safed Koh of western Afghanistan farther west. On the north-north-west are the deep defiles of the southern feeders of the Oxus, while the Murghab drains the north-western hills and loses itself in the wastes of Turkistan. The Hari Rud runs parallel to and north of the Koh-i-Baba and Safed Koh of the west, giving a site to Herat as it leaves the hills, and turns north to lose itself like the Murghab. The southward rays of the fan have rivers between them which reach through the desert of Registan to the lake-swamp of Seistan; the chief of these is the Helmand. At the emergence of one of the feeders of the Helmand from the hills, above the desert, stands Kandahar, a focus for numerous valleys, and also related to the Bolan pass. On the east the tremendous drop from Afghanistan to the Indus lowland has promoted the cutting of deep valleys, notably that of the Khyber pass on a feeder of the Kabul river, which has eaten back among the hill lines right to the Hindu Kush. The northern flank of the fan-mountains, on the west, is the Band-i-Turkistan, a sombre line overlooking the immense Chul, a loess area stretching away northwards to the Oxus.

The complexity of the Kabul river feeders is an important factor of the existence of the historic city of Kabul. From the city one may follow lines between the ridges southwards to Ghazni and to Kandahar, or the line of the Hari-Rud westwards to Herat, or one may go north over either the Hindu Kush (via the Unai pass) or Koh-i-Baba (via the pass of Irak) and so down the tremendous defiles of the Balkh river or one may skirt round the north-east of the Koh-i-Baba at a lower level via Charikar and the Shibar pass. By taking the last route one avoids getting more than 10,000 ft. above sea-level and this route is not often snowbound for long. It is the historic way. In the 19th century somewhat more direct ways from the Oxus to Kabul have been developed farther east. From Kabul into India one route much used in historic times left the Kabul river above Jalalabad and went north-east across the Kunar, thence into Bajaur and so via Malakand or some route near it into the Indian plains. The famous Khyber pass is entered beyond the fort of Jamrud, 11m. W. of Peshawar: it follows the Khyber stream up to Landi Kotal, debouching on to the Kabul river at Dakka whence the route goes along to Jalalabad, beyond which are alternative ways to Kabul. The Khyber pass is the part of the route between the entry to the mountains west of Jamrud and the emergence above at Landi Kotal and it lies within the North-West Frontier Province of India.

The Bara route farther south leads up into the heart of the Tirah country. The Kurram river route with the Peiwar (8,600ft.) and Shutargardan (10,800ft.) passes across the southern extensions of the Safed Koh (note the resemblance to the name of the range in western Afghanistan) is the next route southwards. The Tochi river route leads to Ghazni whence, in the days of its power, many raids were made upon the Indian plains. The Gomal river route has considerable commercial importance as it involves no very difficult pass though it is forced to leave the river because of very

narrow precipitous defiles. From Kandahar a route skirts the ends of the hill lines to the frontier at Chaman whence it goes through the Kojak pass down to Kila Abdullah; it has considerable trade.

In spite of much work spread over many years some of the physical features of Afghanistan are still undetermined, the rugged nature of the country being a severe handicap to research.

Climate.—In the north the climate is extreme. In winter, waves of intense cold occur with temperatures ranging from -12° F. to 15° F., while in summer the shade temperature in the Oxus region may reach 110° or 120° F. For seven months of the year (May–November) the temperature-range exceeds 30° F. daily, this range being greater than that of the days in the cold season. In Kabul snow lies for two or three months and people stay indoors near the stoves. At Ghazni also snow lasts long and tradition tells of disastrous snowstorms. Everywhere, however, summer heat is great, but this is especially the case all around Kandahar; this country in summer suffers from dust storms and snow rarely lies on the plains in winter. Herat has a strong north-west wind and relatively mild temperature throughout the summer and in winter the snow rarely lies long; but above Herat fierce winter cold prevails and the upper part of the Hari Rud river freezes, rapids and all.

The south-west monsoon brings rain only to the valleys that lead down from Afghanistan to the Indus plains, the Kabul valley as far as Laghman, the eastern ends of the Safed Koh, of the east and the Kurram valley. It therefore does not bring rain to Afghanistan which gets much of its precipitation as winter snow and a small but very important contribution of rain in spring. Snow and spring rain come largely from the north-west and in winter the snow-winds are intensely cold. The atmosphere is dry and the brilliant sunshine of a large part of the year, with very bright clear nights also, is a feature.

Vegetation.—On the main ranges at 6,000 to 10,000 ft. grow large forest trees, among which conifers are most prominent, such as *Cedrus deodara*, *Abies excelsa*, *Pinus longifolia*, *P. pinaster*, *P. pinea* (the edible pine) and the larch. Yew, hazel, juniper, walnut, wild peach and almond are also found. Growing under the shade of these are several varieties of rose, honeysuckle, currant, gooseberry, hawthorn, rhododendron and luxuriant herbage, the Ranunculaceae being abundant and rich in genera. The lemon and wild vine are commonest on the northern mountains. The walnut and oak (evergreen, holly-leaved and kermes) descend to the secondary heights, where they become mixed with alder, ash, khinjak, *Arbor-vitae*, juniper, *Indigoferae* and dwarf laburnum, with species of *Astragalus*, etc. Lower again and down to 3,000 ft. grow wild olive, species of rock-rose, wild privet, acacias and mimosas, barberry and *Zizyphus*; and, in places, *Chamaerops humilis* (which is applied to a variety of useful purposes), *Bignonia* or trumpet flower, sissu, *Salvadora persica*, verbena, acanthus, varieties of *Gesnerae*. The lowest terminal ridges, especially towards the west, are naked in aspect. Their scanty vegetation is almost wholly herbal; shrubs are only occasional; trees almost non-existent. Labiate composite and umbelliferous plants are most common. Ferns and mosses are almost confined to the higher ranges. On the dreary Kandahar table-lands grow many vigorous plants, such as papilionaceous *Leguminosae*, and the camel-thorn (*Hedysarum Alhagi*), *Astragalus* in several varieties, spiny rest-harrow (*Ononis spinosa*), the fibrous roots of which often serve as a tooth-brush; plants of the sub-family *Mimosae*, such as the sensitive mimosa; a plant of the rue family, called by the natives *lipâd*; the common wormwood; also certain orchids, and several species of *Salsola*. Rue and wormwood give domestic medicines—the former for rheumatism and neuralgia; the latter for fever, debility and dyspepsia, as well as for a vermifuge. The *lipâd*, of heavy nauseous odour, is believed to keep off evil spirits. On some sides and hollows of ravines are found rose-bay (*Nerium Oleander*), called in Persian *khar-zarah*, or assbane, wild laburnum and various *Indigoferae*.

The chief cultivated trees are mulberry, willow, poplar, ash, and occasionally the plane.

Of commercial value is the gum-resin of *Narthex asafetida* of the high and dry plains of western Afghanistan, especially between

Kandahar and Herat. The Kakar clan collects this gum-resin; and the depot is Kandahar, whence it finds its way to India, for use as a condiment. It is not used in Afghanistan, but the Seistan people eat the green stalks preserved in brine. In the highlands of Kabul edible wild rhubarb is an important local luxury. The bleached rhubarb, which has a very delicate flavour, is obtained by covering the young leaves as they sprout with loose stones or an empty jar. Leaf-stalks are gathered and carried down for sale. Bleached and unbleached rhubarb are both largely consumed, both raw and cooked. Walnut and edible pine-nut are both wild growths, which are exported. The *sanjīt* (*Elaeagnus orientalis*), common on the banks of watercourses, furnishes an edible fruit. The dried tuber of a mountain orchis affords the nutritious mucilage called *salep*; a good deal of this goes to India. *Pistacia khinjak* affords a mastic. The fruit, mixed with its resin, is used for food by the Achakzais in southern Afghanistan. The true pistachio is found only on the northern frontier; the nuts are imported from Badakhshan and Kunduz. Mushrooms and other fungi are largely used as food, especially by town Hindus as a substitute for meat. Manna, of at least two kinds, is sold in the bazaars. One, called *turanjbin*, appears to exude, in small round tears, from the camel-thorn, and also from the dwarf tamarisk; the other, *sir-kasht*, in large grains and irregular masses or cakes with bits of twig imbedded, is obtained from a tree which the natives call *siah chob* (black wood), thought by Bellew to be a *Fraxinus* or *Ornus*.

Agriculture.—In most parts of the country there are two harvests, as generally in India. One of these, called by the Afghans *bahārak*, or the spring crop, is sown in the end of autumn and reaped in summer. It consists of wheat, barley and a variety of lentils. The other, called *pāizah* or *tirmāi*, the autumnal, is sown in the end of spring and reaped in autumn. It consists of rice, varieties of millet and sorghum, of maize, *Phaseolus mungo*, tobacco, beet, turnips, etc. The loftier regions have but one harvest. Wheat is the staple food; rice is not largely distributed. In the eastern mountains *bājra* (*Holcus spicatus*) is the chief grain. Most English and Indian garden-stuffs are cultivated, turnips in some places very largely, as cattle food. The growing of melons, water-melons and other cucurbitaceous plants is very important near towns. Sugar-cane is grown only in the rich plains; and though cotton is grown in the warmer tracts, most of the cotton cloth is imported.

Madder is part of the spring crop near Ghazni and Kandahar and in the west and supplies the Indian demand. It is said to be very profitable, though it takes three years to mature. Saffron is grown and exported. The castor-oil plant furnishes most of the oil of the country. Tobacco is very general; that of Kandahar is exported to India and Bokhara. Two crops of leaves are taken.

Lucerne and a trefoil called *shaftal* form important fodder crops in the west, and, when irrigated, are said to afford ten or 12 cuttings in the season. The *komal* (*Prangos pabularia*) is abundant in the hill country of Ghazni, and is said to extend through the Hazara country to Herat. It is stored for winter fodder. Others are derived from the *Holcus sorghum*, and from two kinds of panick. It is common to cut down the green wheat and barley before the ear forms, for fodder, and the repetition of this, with barley at least, is said not to injure the grain crop. Bellew gives the following statement of the manner in which the soil is sometimes worked in the Kandahar district:—Barley is sown in November; in March and April it is twice cut for fodder; in June the grain is reaped, the ground is ploughed and manured and sown with tobacco, which yields two cuttings. The ground is then prepared for carrots and turnips, which are gathered in November or December.

European fruits are of many varieties and excellent quality. Fresh or preserved, they form a principal food of a large class of the people, and the dry fruit is largely exported. In the valleys of Kabul mulberries are dried, and packed in skins for winter use. This mulberry cake is often reduced to flour, forming in some valleys the staple food. Vines are sometimes trained on trellises, but most frequently over ridges of earth 8 or roft. high; they produce round Kandahar must be enormous.

Open canals are usual in the Kabul valley, and in eastern Afghanistan generally; but in the west much use is made of the *karez*, a subterranean aqueduct uniting waters of several springs and conducting their combined volume to the surface at a lower level.

Wild mammals include the tiger in the north, the common leopard and other cats, wolves, jackals, foxes and hyenas among the dog tribe, goats, wild sheep, gazelles, deer, Himalayan varieties of markhor and ibex, wild hogs, wild asses (*Equus onager*). Afghanistan seems to furnish a retreat for the breeding season for many Indian and perhaps some African birds, while in winter its bird life is akin to that of lands farther north.

Of domestic animals, the one-humped camel is cared for and is a stronger breed than the taller one used in India. The two-humped camel is used in the north. The yabu, an indigenous horse, is strong and heavy-shouldered and about 14 hands high; it cannot do fast work nor stand great heat. The breed was improved by Abdur Rahman and those bred in the north are exported to India. Humped cows are kept for milk in the south and south-west, pressed and dried curd being largely eaten; it is said to be a Mongol introduction. Fat-tailed indigenous sheep are either white or russet; the white fleeces are exported to Persia and to Europe via Bombay. Mutton salted and dried in the sun is one of the chief foods of the nomad people who also use beef and camel's flesh in the same way. Goats and dogs (pointers and greyhounds) are also noteworthy.

Minerals.—A little gold is taken from the streams in Laghman and the adjoining districts. Famous silver mines were formerly worked near the head of the Panjshir valley in Hindu Kush. Kabul gets iron from the Permuli (or Farmuli) district, between the Upper Kurram and Gomul. Iron ore is most abundant near the passes leading to Bamian, and in other parts of Hindu Kush. Copper ore from various parts of Afghanistan has been seen, but it is nowhere worked. Lead is found in Upper Bangash (Kurram district), and in the Shinwari country; also among the branches of the Safed Koh of eastern Afghanistan and in the Kakar country. There are reported to be rich lead mines near Herat scarcely worked. Lead, with antimony, is found near the Arghandab, 32m. N.W. of Ghazni, and in the Ghorband valley, north of Kabul. Most of the lead used, however, comes from the Hazara country, where the ore is described as being gathered on the surface. A large and elaborate ancient mine exists at Feringal, in the Ghorband valley. Antimony is obtained at Shah-Maksud, about 30m. N. of Kandahar. Sulphur is said to be found at Herat, dug from the soil in small fragments, but the chief supply comes from the Hazara country and from Pirkisri, on the confines of Seistan, where there would seem to be a crater, or fumarole. Sal-ammoniac is brought from the same place. Gypsum is found in large quantities in the plain of Kandahar, being dug out in fragile coralline masses from near the surface. Coal (perhaps lignite) is found at least in the Ghorband valley and near the Khurd Kabul pass. Nitre abounds in the soil over all the south-west of Afghanistan, and often affects the water of the karez or subterranean canals. Rubies, turquoises and first-quality lapis lazuli come from Badakhshan. This last material, especially, is smuggled to the north.

People.—The term Afghan really applies to one section only of the people, but this is the dominant section known as the Durani. The Ghilzai (almost as powerful as the Durani) claim to be of Turkish origin; the Hazaras, the Chahar-Aimak, Tajiks, Uzbeks, Kafirs and others are more or less subject races. Popularly any inhabitant of Afghanistan is known as Afghan on the Indian frontier without distinction of origin or language; but the language division between the Parsiwan (or Persian-speaking Afghan) and the Pathan of the Indian frontier is a very distinct one. The predominance of the Afghan in Afghanistan dates from the mid-18th century, when Ahmad Shah carved out Afghanistan from the previous conquests of Nadir Shah and called it the Durani empire.

The Durani Afghans claim to be Ben-i-Israel, and insist on their descent from tribes carried away captive from Palestine to Media by Nebuchadnezzar. Yet they also claim to be Pukhtun (or Pathan) in common with all other Pushtu-speaking tribes, whom they

do not admit to be Afghan. The bond of affinity between the various peoples who compose the Pathan community is simply the bond of a common language. All of them recognize a common code or unwritten law called Pukhtunwali, which appears to be similar in general character to the old Hebraic law, though modified by Mohammedan ordinances, and strangely similar in some points to Rajput custom. Besides their division into clans and tribes, the whole Afghan people may be divided into dwellers in tents and dwellers in houses; and this division is apparently not coincident with tribal divisions, for of several of the great clans at least a part is nomad and a part settled. Such is the case with the Durani and with the Ghilzai.

Dominant Stock.—Afghans have fine figures, aquiline profiles, fair complexions, and a small group yielded an average cephalic index of 74.8, a value nearer to that found among Rajputs in India than to that among the Pukhtun (Pathan) groups (av. cephalic index 80–83) of the Indian frontier or to that among some of the subject peoples. Among the latter, the Hazaras are tall, very broad-headed (average cephalic index 85.0), and akin in feature to peoples of parts of Turkistan and Mongolia; they are said to have been planted in Afghanistan by Jenghiz Khan and they inhabit especially the mountains west of Kabul. The Tajiks are as broad-headed as the Hazaras but belong to the pale rosy-skinned rather than to the yellow-skinned stock; they seem to be an old established, settled, agricultural people.

Tribal law, with the custom of hospitality, and the vendetta in many forms are rules of life, and even the settled Afghan is very much a soldier. They are able to endure great privation and are sober and stern, and may often become cruel. They have long been free of law and have looked upon taxation as interference to be resisted by force, but now the "modernization" of Afghanistan is said to be proceeding apace.

The cultivators, including owners, tenants, labourers and slaves, are skilled irrigators, utilizing every fragment of profitable land; some of the Ghilzai are specially skilled in building underground water-channels (*karez*). The settled folk live chiefly in village communities and leave handicraft and commerce largely to subject races save that some Ghilzai are wandering traders (*powindaks*). Afghanistan is a stronghold of Islam, of the Sunni sect for the most part, though the Hazaras and others are Shiah. The Kafirs, as the name implies, are non-Mohammedans, living in Kafiristan (E.N.E.); other tribes of the Indian border are recent converts to Islam. Some of the Durani Afghans of Kandahar and Zamindawar districts are very fanatical "Ghazis," that is, men who have vowed their lives to the extinction of other creeds.

Language and Administration.—The official language of Afghanistan is Persian, which is also the vernacular of the people west of the Helmand; Pushtu is more widely spoken, especially towards the east, but is unknown in the west; Turki is spoken in the north. There is a respectable amount of Afghan literature. The oldest work in Pushtu is a history of the conquest of Swat by Shaikh Mali, a chief of the Yusufzais, and leader in the conquest (A.D. 1413–24). In 1494 Kaju Khan became chief of the same clan; during his rule Buner and Panjkora were completely conquered, and he wrote a history of the events. In the reign of Akbar, Bayazid Ansari, called Piri-i-Roshan, "the saint of Light," the founder of an heretical sect, wrote in Pushtu, as did his chief antagonist, a famous Afghan saint called Akhund Darweza. The literature is richest in poetry. Abdur Rahman (17th century) is the best known poet. Another very popular poet is Khushal Khan, the warlike chief of the Khattaks in the time of Aurangzeb. Many other members of his family were poets also. Ahmad Shah, the founder of the monarchy, likewise wrote poetry. Ballads are numerous. Much of the literature is in Persian. The village Mullah or priest teaches the boys reading and writing and religion through the Koran; the Afghan noble has long known Persian and there is an old-established traditional lore in religion and medicine. But of late a good deal has been done to modernize education, by teaching agriculture, by developing free secondary schools including one under French and one under German supervision, by opening two colleges in Kabul, one for army officers and one for administrators, as well as other colleges elsewhere. Afghan stu-

dents in recent years have been sent to France and Germany. The Government was an absolute monarchy until 1922 when a legislative and a State assembly were organized with a cabinet under the presidency of the king, Amanullah Khan (born 1892, succeeded to the throne 1919), who took the title of king in 1926 in place of that of Amir. Ministers are appointed for foreign affairs, internal affairs, education, commerce, justice, revenue and war. There are five major provinces: Kabul, Kandahar, Herat, Mazar-i-Sharif, and Kataghan-Badakhshan, and four minor provinces Jalalabad, Khost, Farah and Maimana. Each province is under a governor. The law is that of Islam with courts in each seat of Government and appeals to higher courts and ultimately to a supreme one at Kabul. The army is a short service conscript one, but tribal groups also count for a great deal; there are armament factories at Kabul, and, by a treaty of 1921, the Afghans may import munitions through India. Herat in the west and Dehdadi near Balkh in the north are strongly fortified. A new currency was established in 1926, and revenue is mainly from customs. A subsidy was formerly paid by the Indian Government to the Amir but that ceased, by agreement, in 1919. There is no regular budget but the public revenue is still under £1,000,000. There are neither banks nor railways, nor is Afghanistan as yet in the International Postal Union, but some waterfalls, notably that of Djebel-us-Seradj, are utilized as sources of hydro-electric power. Railways reach the Afghan frontier at various points from the British side and also from the Russian side. The Khyber railway goes up to Landi Kotal.

Communications and Industries.—There are no railways, but telegraphic communication exists between Kabul and Peshawar; telephones exist in some of the towns, and Kabul has a wireless installation.

Great Britain, France, Germany, Italy, Persia, Russia and Turkey have legations at Kabul. Kabul (pop. 100,000) is the historic centre and the limits of its authority have varied greatly from time to time, some mountain regions being practically independent. Herat (pop. 121,000) is largely Persian in character and has often been in rebellion. Kandahar (pop. 60,000) in the south and Mazar-i-Sherif (pop. 46,200) in the north are other important centres.

Silks, felts, carpets, articles made from camels' and goats' hair, sheepskin coats, soap, clothing, boots, etc., are produced at Kabul, chiefly for the army, in factories that are partly instructional. Herat and Kandahar have long been famed for their silks, felts and carpets, though these are not comparable to true Persian ones. Herat and Kandahar gather fine wool from the nomad shepherds. Commerce across the frontiers has been limited by high duties. India sends to Afghanistan cotton goods, dye-stuffs, hardware, etc., while Afghanistan sends into India timber, dried fruits, provisions, drugs (especially *asafoetida*), madder, spices, wool, silk, hides, cattle, tobacco. Merchandise is still carried chiefly on camel or pony back, but timber is floated down the streams where that is possible. Cattle go in greater number into Soviet territories and food stuffs are also exported in that direction, while imports from Russian lands into northern Afghanistan include wool and cotton. Trade with Persia is of little account.

The basin of the Kabul river especially abounds in remains of the period when Buddhism flourished. Bamian is famous for its wall-cut figures and at Haibak (on the route between Tashkurgan and Kabul) there are some most interesting Buddhist remains. In the Koh-Daman, north of Kabul, are the sites of several ancient cities, the greatest of which, called Beghram, has furnished coins in scores of thousands, and has been supposed to represent Alexander's Nicaea. Nearer Kabul, and especially on the hills some miles south of the city, are numerous topes. In the valley of Jalalabad are many remains of the same character.

In the valley of the Tarnak are the ruins of a great city (Ulan Robot) supposed to be the ancient Arachosia. About Girishk, on the Helmand, are extensive mounds and other traces of buildings; and the remains of several great cities exist in the plain of Seistan, as Pulkī, Peshawaran and Lakh, relics of ancient Drangiana. An ancient stone vessel preserved in a mosque at Kandahar is almost certainly the same that was treasured at Peshawar in the 5th

century as the begging pot of Sakya-Muni. In architectural relics of a later date than the Graeco-Buddhist period Afghanistan is remarkably deficient. Of the old city of Ghazni, the vast capital of Mahmud and his race, no substantial relics survive, except the tomb of Mahmud and two remarkable brick minarets. A vast and fruitful harvest of coins has been gathered in Afghanistan and the adjoining regions. The concession for archaeological exploration in Afghanistan has been given to France. Regarding the proprietorship of finds, it may be noted that the adoption of regulations such as are in force in Egypt is being considered.

Present-day Army.—The present military system dates from the days of Abdur Rahman who in 1896 introduced semi-compulsory service which provided that one man in every eight between the ages of 16 and 70 should take his turn in undergoing military training. In 1917 an organization was introduced to provide corps (Urdu) of all arms with a personnel of about 24,000 combatants, divisions of all arms with about 12,000 and mixed brigades with about 4,000, all with mounted troops in the proportion to infantry of one to six, with a six- or four-gun battery attached to each infantry "battalion." Recruitment is practically for life, but nominally discharge can be obtained after 3 years if a substitute is forthcoming. The king is head of the army, with a commander in chief as executive commander, and subordinates for the army formations. The headquarters of the military districts are Kabul, Jalalabad, Kost, Ghazni, Mukur, Kandahar, Farak, Herat, Maimana, Mazar-i-sharif and Faizabad. The distribution of troops is irregular. Kabul has the most. Practically all Afghans being armed with modern rifles, estimates of fighting strength are misleading. Taking the population at 6,000,000, an estimate of about 1,200,000 of fighting age would be somewhere near the mark. The size of mobile formations would depend upon success in collecting transport. Some motor transport is kept at Kabul. There are military academies at Kabul and Herat, military schools for cadets at Kabul, Ostalif and Jalalabad, but the majority of officers seem to be drawn from other sources. Kabul and other places have defences. Herat and Dehdali near Balkh are credited with being the chief fastnesses in Northern Afghanistan, the latter covering the roads leading from the Oxus into Afghan Turkistan. According to travellers' reports, attention is being directed to the development of air forces. Visits to Kabul of Russian aircraft and negotiations for their purchase have been reported, the Russians desiring to provide the pilots.

BIBLIOGRAPHY.—Afghanistan is one of the few countries for which information about armaments is not to be found in the League of Nations *Armaments' Year Books*. Foreign travellers were not encouraged by the present King's predecessors. The preceding notes are from the best accessible reports, culled from many sources. Among the most recent is an English translation by B. K. Featherstone of *Through the heart of Afghanistan* by Emil Trinkler (Faber and Gwyer, 1928). (G. G. A.)

HISTORY

The geographical term Afghanistan ("land of the Afghans") is an anachronism as applied to the country before 1747, when it first became a separate and independent state, and though it is now the official name of the kingdom it is not in common use among the Afghans.

The Afghan chroniclers call their people *Ben-i Israil*, or "Children of Israel," and claim for them descent from King Saul, whom they call *Tālūt*, through a son named Jeremiah, who is said to have had a son named Afghana; but this legend assumes so many conflicting and improbable forms that it may be safely regarded as a late invention. According to one account Afghana was settled by Sulaiman (Solomon) in the Sulaiman Mountains, and according to another, evidently connected with the account of the captivity of the Ten Tribes, his descendants were removed

from Palestine by Nebuchadrezzar and found their way to the mountainous country about Herat. Another legend related that in pre-Islamic times Bilo (father of the Biluchis), Uzbek (father of the Uzbaks) and Afghana were considered as brethren. The historian Firishta cites a legend which makes the Afghans Copts, of the race of Pharaoh; and the Afghans explain their conversion to Islam by a story to the effect that nine years after Mohammed's announcement of his mission a holy man named Kais, sent to Medina to make inquiry of him, became a zealous Muslim and on his return converted his countrymen, adding that all true Afghans are descended from Kais and his three sons, but ignoring the other descendants of Afghana. Omitting the legend which attributes to the Afghans a Coptic descent we find the grandson of King Saul made contemporary with Mohammed Uzbek Khan, who flourished in the 14th century, as well as with King Solomon; and Kais, whose name suggests Kish, Saul's father, made contemporary with the prophet Mohammed.

Despite these and other discrepancies some intelligent British officers, well acquainted with the Afghans, have accepted the story of their Hebrew descent. Their belief has been based on certain Afghan customs and on the fancied resemblance of a well-known type of Afghan physiognomy to the physical characteristics of the Jews; but the Afghans, as Muslims, have many customs similar to those of the Hebrews, and they share their physical resemblance to the Jews with other races in no way connected with them.

Early Period.—Until 500 B.C. Afghanistan formed part of the Achaemenian empire, and comprised the ancient provinces of *Aria*, or *Hari Rud*; *Bactria*, or *Balkh*; *Drangiana*, or *Seistan* and the *Helmand Valley*; *Arachosia*, or *Kandahar*; and *Paropamisus*, the region of the Hindu Kush and Kabul. The population in the north was Iranian, and in the south contained a large Indian element; but the most interesting people mentioned in the Greek records are the *Paktyes* in Arachosia, which Herodotus calls *Paktye*, for in their name we may trace that of the *Pakhtun* or *Push-tun*, by which the Afghans still describe themselves. The story of Alexander's campaign in the eastern provinces of the Persian empire need not be repeated here, but the cities of Herat (Alexandria Arion) and Kandahar (Alexandria Arachosion) were either founded or restored by him.

He was succeeded in the eastern provinces of his empire by Seleucus Nicator, the founder of the Seleucid dynasty, but the Indian provinces and the Kabul valley fell to Chandragupta (*Sandracottus*), the founder of the Maurya dynasty.

Greek Dynasty.—As the power of the Seleucids waned an independent Greek dynasty was established, about 246 B.C., in Bactria, and about 50 years later annexed a great part of north-western India, but Afghanistan passed from its possession into that of the Parthians (who occupied its western provinces), and the Sakas, a Scythian tribe, who conquered the eastern provinces about 130 B.C. and gave their name to Seistan (*Sakastan* or *Sakastene*). Within 200 years the Yue-chi (*q.v.*), another central Asian tribe, expelled the Parthians and founded the Kushan dynasty, which ruled Afghanistan, and, at the height of its power, northern India, as far as Benares on the east and Malwa on the south. This dynasty adopted the Buddhist religion, and Kanishka, the greatest king of the line, convened the great council which settled the canon of northern Buddhism, and is mentioned as a champion of Buddhism by Hiuen Tsang, the Chinese pilgrim; al-Biruni, the Mohammedan traveller, philosopher, and geographer; and in the Mongol versions of the Buddhist story.

The empire of Kanishka did not long survive his death, but kings of his race, known as the Turki Shahs, were found by Hiuen Tsang reigning in the Kabul valley in the 7th century, and were not overthrown until the end of the 9th century, when a Hindu dynasty known as the Hindu Shahi ousted them.

The Caliph Empire.—The title of Arab conquest and Islamic propaganda in the 7th century reached western Afghanistan, which was included in the empire of the Caliphs, but did not touch the kingdom of Kabul, which remained independent under the Turki Shahi and Hindu Shahi kings. As the power of the Caliphs declined their provincial governors founded dynasties owning a

nominal allegiance to them but virtually independent. One of the earliest of these was the Arab dynasty of the Tahirids, who included Herat and Balkh in their kingdom of Khurasan, in which they were succeeded by a native Persian dynasty, the Saffarids, who were overcome in the 9th century by the Samanids of Balkh and Bukhara, another Persian house. Alptigin, a Turkish slave of this house, established himself in Ghazni, where he was succeeded, after a short interval, by another Turkish slave, Sabuktigin, who threw off the yoke of the Samanids and annexed to his dominions not only the Hindu kingdom of Kabul, but the territory lying between it and the Indus. Assistance given by him to the Samanids was rewarded with the government of Khurasan, to which he appointed his elder son Mahmud, and Afghanistan became the nucleus of a great empire. Sabuktigin died in 997, and his son Mahmud, after deposing a younger brother, ascended the throne in 998. The tale of his predatory raids into India need not be repeated here. He added to his empire Baluchistan, and, later in his reign, the Indian kingdom of the Punjab, the province of Multan, and the greater part of western Persia, and divided with Ilak Khan, the founder of a Turkish dynasty in Transoxiana, the dominions of the house of Saman, which came to an end during his reign.

The hitherto obscure town of Ghazni now became a great and splendid city, for Mahmud was no mere ravager and despoiler. It is in Mahmud's reign that we first hear of the small state of Ghor, in the southern ranges of the Safid Kuh, which Mahmud reduced to vassalage, and the rulers of which, eventually, extinguished his dynasty. He himself paved the way for the destruction of his empire by admitting into Khurasan the Seljuk Turks, who afterwards stripped his descendants of their possessions in the north and west and founded a great empire on the ruins of that of Ghazni.

Mahmud died in 1030 and his descendants continued to reign over a gradually diminishing empire, with Ghazni as their capital, until 1153, when Alauddin Husain, chief of Ghor, to avenge the death of his brother, Saifuddin, who had been treacherously put to death by the sultan of Ghazni, captured and burnt the city, driving Mahmud's descendant, Khusrav Shah, into the Punjab. The destruction of the great city of Ghazni earned for its author the cognomen of *Jahansuz*, "the World-Burner."

Ghor Dynasty.—In 1186 the World-Burner's nephew, Muizzuddin Mohammed, commonly known as Mohammed Ghori, treacherously enticed Khusrav Malik, the last of the Ghaznavids, from Lahore, and imprisoned him for the short remainder of his life. Having secured the Punjab, Mohammed invaded India, and founded there a Muslim empire which endured, in name at least, until 1858.

This dynasty of Ghor is commonly believed to have been of Afghan origin, but the belief rests on a very slender foundation of evidence. Legend also assigns it descent from Zahak; and though this is no better attested than their Afghan genealogy, it seems to be probable that they were Tajiks of Persian race. The Afghans themselves are Indo-Iranian by race, and their antiquity as a separate people is uncertain. Firishta's statement that the inhabitants of the Sulaiman mountains were known as Afghans in the 1st century of the *Hijra* (the 7th century of the Christian era) carries no weight, but the name occurs in al-'Utbi's *History of Sultan Mahmud*, written about A.D. 1030, coupled with that of the Khalaj or Khaljis, who were apparently a Turkish tribe domiciled in western Afghanistan, but always antagonistic to the true Afghans. Both names occur in the history of India during the 13th and 14th centuries, and the Indian historians are not careful to distinguish between the two peoples. Hence it is, probably, that some Europeans have carelessly classed all the five dynasties which preceded the Timurids on the throne of Delhi as "Pathans," or Afghans, though in fact two of them were Turkish, one was Khalji, and one was of Arab descent.

The Muslim empire in India was founded by a manumitted slave of Mohammed Ghori, and shortly after Mohammed's death his great empire fell to pieces and was divided between provincial governors and members of his own family holding small principalities in Afghanistan. These petty princes were subdued by

the shahs of Khvarazm, or Khiva, of whose great but ephemeral empire Afghanistan for a time formed part.

Mongol Rule.—In the 13th century Afghanistan, like Persia, suffered the dreadful calamity of invasion by the heathen Mongols of Jenghiz Khan, who settled to the north of the Hindu Kush; but the rest of the country, owing to its inhospitable nature, suffered less than more fertile and populated lands. It was here, however, that the gallant Jalaluddin, last of the shahs of Khvarazm, made his most strenuous efforts to avenge on these savages the annexation and devastation of his kingdom.

The greater part of Afghanistan remained under Mongol rule until the rise of Timur Lang (Tamerlane), who established himself in northern Afghanistan in the latter part of the 14th century, wresting Herat from the Kurts, a family which claimed descent from the princes of Ghor (*see* MONGOLS).

The Moghul Empire.—In 1504, Babur, fifth in descent from Timur, having been expelled from his ancestral dominions in Transoxiana, occupied Kabul and made it the capital of a kingdom which he established in Afghanistan; and in 1522 he captured Kandahar from the Afghans, a Moghul family which had long held it, but he did not remain long content with his Afghan kingdom. In 1526 he invaded India, defeated Ibrahim Lodi, the Afghan Sultan of Delhi, on the field of Panipat, and founded the state which is usually known to Europeans as the Moghul empire, though Babur was no Moghul, and would have resented the designation. Kabul and Kandahar remained for the time merely provinces of Babur's Indian empire, and Herat fell into the hands of the Safavi shahs of Persia.

Babur's son, Humayun, was expelled from India by the Afghan, Sher Khan, and was compelled to seek an asylum with Shah Tahmasp of Persia, who helped him to recover Kandahar, held by his rebellious brother. From Kandahar Humayun proceeded to Kabul, from which city he ousted another brother, and after spending seven years in re-establishing his authority in Afghanistan was able, in 1554, to recover his Indian empire, but died shortly afterwards, as the result of an accident, leaving the task of extending and consolidating the dominions of his house in India to his young son Akbar (*q.v.*), the real founder of the "Moghul" empire of India.

Afghanistan was then divided, Kabul remained a province of India, and Herat a province of Persia; Balkh fell to the Uzbaks of Transoxiana, and Kandahar, after remaining for a time in the possession of the Timurids, was taken by the Persians. Akbar's grandson, Shah Jahan, made a disastrous attempt to recover Balkh and twice endeavoured to recover Kandahar, but without success.

In 1708 the Ghilzais of Kandahar, who perhaps represented the Khalaj, provoked by the oppressive rule of the Persian governor, Shahnavaz Khan, a Georgian prince of the Bagratid house, rose under Mir Vais and expelled the Persians. Mir Vais defeated the Persian armies sent against him and established his independence, but died in 1715. His son Mahmud, carrying out a project of his father's, invaded Persia, besieged Isfahan, and in Oct. 1722, compelled Shah Husain, the feeble Safavid, to surrender his crown to him, but the rule of the Ghilzais in Persia was brief—Mahmud died mad and his successor, Ashraf, was defeated by Nadir Kuli, the Afshar, who shortly afterwards ascended the throne. In 1737–38 Nadir Shah, one of Persia's greatest monarchs, recovered Kandahar and conquered the Indian province of Kabul, but conciliated the Afghans and enlisted many in his army—among them Ahmad Khan, a young chieftain of the Sadozai family of the Abdali tribe. Ahmad Khan rose to high rank in the Persian army, and after the assassination of Nadir Shah in 1747 was chosen by the Afghan chiefs at Kandahar as their leader and assumed the royal title. Among his titles was that of *Durr-i-Dauran*, "the Pearl of the Age," from which his tribe received the name of Durrani.

The land of the Afghans had been successively a congeries of petty states, the centre of great empires ruled by foreigners, and a dismembered country, furnishing provinces to three monarchies. It now became, for the first time, a distinct political entity, ruled by an independent native sovereign.

Ahmad Shah Abdali extended his kingdom westward nearly to the Caspian and eastward over the Punjab and Kashmir, which he wrested from the feeble successors of Babur on the throne of Delhi. He claimed and commanded the allegiance of Sind, which had been ceded by Mohammed Shah of Delhi to Nadir Shah. His northern boundary was the Oxus, and Baluchistan and Khurasan were tributary states of his kingdom. At the third battle of Panipat, fought on Jan. 6, 1761, he inflicted on the confederate Maratha chiefs, who were then at the zenith of their power and were the real masters of the great empire founded by Babur and Akbar, a crushing defeat, and with inferior numbers nearly annihilated their great army.

Foreign Influences.—Ahmad Shah died in 1773 and was succeeded by his son Timur, who transferred his residence from Kandahar to Kabul. In his reign Sind was lost, Balkh and other districts in Afghan Turkistan became virtually independent, and the seeds of revolt were sown in Khurasan and Kashmir. He died in 1793, leaving 23 sons, of whom the fifth, Zaman Mirza, by the help of Payinda Khan, head of the Barakzai family of the Durrani, ascended the throne. His reign was short and troubled and was marked by one act destined to have momentous consequences—the grant of Lahore, in 1799, to the Sikh adventurer, Ranjit Singh. In the same year Mahmud, another son of Timur, ousted Zaman Shah and ascended the throne, but in 1803 was deposed by conspirators who placed his brother, Shuja-ul-Mulk, on the throne. In 1809 the East India Company's government in India, alarmed by the intrigues of Napoleon in Persia, sent Mr. Mountstuart Elphinstone as envoy to Shah Shuja at Peshawar, but Napoleon's ambitious eastern schemes came to nought and the British mission at Peshawar was unable to effect anything, for Shah Shuja's rule was unpopular, and while his army was engaged in quelling a rebellion in Kashmir his deposed brother, Mahmud, rose in rebellion, defeated him and put him to flight, and ascended the throne for the second time. In 1815 Shah Shuja took refuge in India and remained a pensioner of the Indian Government until, at a later date, a use was found for him. Mahmud ruled until 1818 but the real ruler of the kingdom was Fath Khan the Kingmaker, the eldest son of Payinda Khan Barakzai. It was he who recovered Herat, which had been seized by the Persians, and in the insolence of his power he ventured to offer a gross outrage to the Sadozai family. Mahmud, already chafing under Fath Khan's yoke, avenged the insult by causing him to be blinded, and Mohammed Azim and Dost Mohammed, the minister's brother and half-brother, rose in arms against Mahmud, who retorted by causing Fath Khan to be put to death with torture. The Barakzais prevailed and in 1818 drove Mahmud from Kabul and dethroned him. A period of anarchy then ensued. Mohammed Azim ruled Kabul, but his brothers and other Afghan chiefs, the provincial governors, withheld their allegiance from him and the kingdom fell to pieces. Herat, always a Persian rather than an Afghan town, was alienated; Afghan Turkistan and Badakhshan regained their independence, and Ranjit Singh, who had already conquered Kashmir, Multan, Dera Ghazi Khan and Attock, was threatening Peshawar, which he secured by defeating the Afghan army at Naushahra in 1823. In the same year Mohammed Azim died, and the remaining Barakzai brothers plunged into a fratricidal war. Three years later Dost Mohammed established himself in Kabul, Ghazni and Jalalabad, and, having secured this fragment of the Afghan kingdom, assumed the title of Amir, after having, in 1835, defeated an attempt by Shah Shuja to regain his throne.

Russia had succeeded France as the bugbear of British administrators in the East, and the fear of Russian intrigue, as well as the prospect of active hostilities between the Amir Dost Mohammed and Ranjit Singh, induced the Company's government to despatch an envoy, Sir Alexander Burnes, to the court of the Amir. His mission was ostensibly commercial, but he was instructed to oppose the attempt of the shah of Persia to recover Herat. He was well received, but the Amir was disappointed by his refusal to pledge his Government to aid him against Ranjit Singh, and consequently held himself in no way bound

to refuse to receive Captain Vikovitch, a Russian officer who then arrived in Kabul. The Governor-General, Lord Auckland, peremptorily demanded his dismissal and the renunciation of all claims to the Punjab and Kashmir, which Ranjit Singh had recovered from the Afghans, and rashly decided to make Dost Mohammed's natural refusal of these demands a *casus belli*, and to attempt to restore the fugitive Shah Shuja, who had already been tried and found wanting. Ranjit Singh, whose material interests were involved, bound himself to co-operate with the British, but when all was ripe for the invasion declined even to permit British troops to cross his territories, though a Sikh force, with Sir Claud Wade and a small British detachment, advanced through the Khyber Pass.

The "Army of the Indus," numbering 21,000, assembled in Upper Sind in 1838 and advanced through the Bolan under the command of Sir John Keane. It met with hardly any resistance and in April, 1839, occupied Kandahar, where Shah Shuja was crowned in his grandfather's mosque. On July 21 Ghazni was taken by storm and Dost Mohammed, deserted by his troops, fled northwards. On Aug. 7 Shah Shuja, escorted by the British army, entered Kabul. It was believed that the war was over, and Sir John Keane, who received a peerage for his services, returned to India with the greater part of the army, leaving Sir William Macnaghten as envoy and Sir Alexander Burnes as his colleague, with 8,000 British and Company's troops and the contingent which had been raised for the service of Shah Shuja for their protection. The trouble was in fact only beginning, for the best of rulers is not acceptable to a free people when imposed upon them by foreign arms, and Shah Shuja had already rendered himself odious to the Afghans. He now, acting on the advice of the British Resident, attempted to raise a regular army to take the place of the tribal militia under its hereditary leaders; but the opposition of the chiefs, who apprehended the diminution of their own power and influence and the extinction of their country's independence, ensured the failure of this design. Shah Shuja was obliged to rely more and more upon British assistance, and his rule grew daily more unpopular. A danger was removed by the surrender of Dost Mohammed, who was sent to India, but it was impossible to save Shah Shuja, and in Nov. 1841, discontent at Kabul culminated in a revolt in which Burnes and other officers were massacred. Akbar Khan, the son of Dost Mohammed, placed himself at the head of the national party, and at a conference with the British authorities stabbed Sir William Macnaghten with his own hand. The British agreed to evacuate the country, and, in accordance with a convention with the Afghans, the garrison, then reduced to 690 British and 3,810 Indian troops, with the enormous number of 12,000 followers, marched out of Kabul on Jan. 6, 1842. The Afghans made no pretence of observing the terms of the convention, and the retreat of the demoralized army in the depth of a severe winter was a scene of confusion and massacre. On Jan. 13 the survivors of the force mustered at Gandamak only 20 muskets, and Dr. Brydon, the sole survivor of the Army of Kabul, except those whom the Afghans had captured, reached Jalalabad alone. The garrison of Ghazni had been obliged to surrender, but Kandahar was held by General Nott and Jalalabad by General Sale. In April, 1842, Shah Shuja was assassinated.

Preparations were made in India to avenge these disasters and to recover the prisoners. In April, 1842, General Pollock forced the Khyber Pass and relieved Jalalabad, and in September re-occupied Kabul, where he was joined by General Nott from Kandahar, who had recaptured and dismantled Ghazni. The prisoners were recovered from Bamiyan, where the Afghans had lodged them, and the army evacuated Afghanistan in Dec. 1842, after destroying the citadel and the central bazaar of Kabul. Dost Mohammed was permitted to return to his country and assumed the government, with the title of Amir.

In 1848, during the second Sikh War, Dost Mohammed was induced to go to the aid of the Sikhs. The adventure was unfortunate for him, for at the battle of Gujarat, in Feb. 1849, his cavalry was ignominiously routed and pursued as far as the hills, and the Peshawar territories were annexed to British India

and thus lost to Afghanistan. Balkh was recovered in 1850 and Kandahar in 1855, in which year also a treaty of peace was concluded between him and the British Government at Peshawar. In 1856 the Persians captured Herat but were obliged to surrender it to an independent ruler after the British expedition to Persia. In 1857 the Amir met, at Peshawar, Sir John Lawrence, who promised him arms and a subsidy to aid him in defending his country against Persia, and a British mission under Major Lumsden was received at Kandahar. During the Indian Mutiny the Amir declined to listen to those who instigated him to aid the rebels, and remained faithful to his alliance.

In 1863 Dost Mohammed captured Herat after a long siege, and, dying almost immediately afterwards, was succeeded by his son Sher Ali Khan, the early years of whose reign were disturbed by contests with his brothers. Early in 1873 the British Government succeeded in obtaining from the Russian Government a declaration that Afghanistan was beyond the field of Russian influence, and the recognition of the Oxus as the northern frontier of the State. Later, the Amir's failure to secure a British guarantee for his sovereignty and family succession, and his refusal to admit British agencies into Afghanistan led to estrangement between him and the British Government, and when, in July, 1878, he ostentatiously received a Russian mission at Kabul and shortly afterwards refused to permit a British mission to cross the frontier, his attitude was regarded as definitely hostile. After some warnings the Government of India delivered an ultimatum, his disregard of which led to the decision to invade Afghanistan. In Nov. 1878, the British forces inflicted severe defeats on the Afghan troops and occupied the Khyber pass and the Kurram valley, and early in 1879 occupied Kandahar, Kelat-i-Ghilzai, and Girishk. The Amir, with the Russian mission, had fled from Kabul, and he died, a fugitive, in March, 1879. His second son, Yakub Khan, who was recognized by the people of Kabul as Amir, voluntarily visited the British camp at Gandamak in May, 1879, and there concluded a treaty, by the terms of which he ceded the Kurram valley, Pishin, and Sibi, and the control of the Khyber and Michni passes and of the tribes in their neighbourhood. He also agreed to receive a British resident at Kabul and to subordinate the foreign affairs of Afghanistan to British influence. Major Sir Louis Cavagnari was well received by him as Resident, but the Amir was either unable or unwilling to control the fanatical element in Kabul, and in Sept. 1879, the Residency was attacked by a mob of townspeople and soldiers, and the Resident and his escort were murdered after a gallant defence.

Abdur Rahman Khan.—The Kandahar force then concentrated at Kandahar, and a force under General (afterwards Field-Marshal Earl) Roberts advanced through the Kurram valley, defeated an Afghan force at Charasia, and occupied Kabul in 1879. Yakub Khan, having entered the British camp, abdicated, and was sent to India, where he lived for the rest of his life. The British force under Roberts remained at Kabul, and in July, 1880, the British Government recognized a new Amir, Abdur Rahman Khan, a grandson of Dost Mohammed and nephew of Sher Ali.

Sardar Sher Ali Khan, a Barakzai of Kandahar, had already been recognized as independent ruler of that province, but in July, 1880, Ayub Khan, a younger brother of Yakub Khan, advanced from Herat, inflicted a crushing defeat on a brigade of British troops at Maiwand and invested Kandahar. On Aug. 8 General Roberts left Kabul with a relieving force, which reached Kandahar on the 31st, and on Sept. 1 defeated the besiegers and captured their camp, artillery, and baggage. Ayub Khan fled with a few followers, and, peace having been restored in southern Afghanistan, the British forces evacuated the country in 1881. Sher Ali was unable to maintain his authority in Kandahar and retired to India, where he ended his days as a pensioner. Ayub Khan again took the field, defeated Abdur Rahman's troops, and occupied Kandahar, but in Sept. 1881, Abdur Rahman utterly defeated him and drove him to seek refuge in Persia. In 1888 he went to India, and lived there as a pensioner of the British Government until his death.

Abdur Rahman had been recognized as Amir of Kabul only, but within a year of ascending the throne had made himself master of Kandahar and Herat also, and he succeeded in quelling tribal disturbances and in establishing his rule on a firm basis. No attempt was made to fetter his independence except with regard to his foreign relations, which he agreed to conduct subject to the control of the Government of India, from whom he received an annual subsidy to be devoted to the payment of his troops and the defence of his north-western frontier, and considerable supplies of war material, together with facilities for importing arms through India at his own cost.

In 1884 it was agreed that a joint commission of British and Russian officers should demarcate the northern boundary of Afghanistan, but the Russian commissioners did not immediately arrive on the scene, and in March, 1885, while the Amir was conferring with Lord Dufferin, the Viceroy of India, at Rawal Pindi, Russian troops attacked and drove from Panjdeh, a small town on the frontier, an Afghan force. In 1888 the Amir's authority was seriously menaced by the revolt of his cousin, Ishak Khan, who held a quasi-independent position as governor of Afghan Turkistan and caused himself to be proclaimed Amir, but the rebellion was crushed. Ishak was expelled and settled at Bukhara as a pensioner of the Russian Government, and Abdur Rahman's authority was established in the northern province. In 1895 he completely subjugated Kafiristan, a wild mountainous tract to the north-east of Kabul, the inhabitants of which had hitherto successfully resisted all attempts to destroy their independence.

In 1901 Abdur Rahman died, after a reign of 21 years, in the course of which he gave Afghanistan a government such as it had never known before. This he effected, first, by substituting for a feudal militia under tribal chiefs a standing army, well trained, well armed, and regularly paid, owing allegiance to none but himself. By means of this force he was able to establish an efficient central administration, retaining all power in his own hands, and to improve the public revenues not only by increasing the burden of taxation, but by ensuring the collection of all assessed taxes. He was harsh and ruthless, but he relieved his subjects from the petty tyranny of local chieftains and he suppressed highway robbery and violent crime. It is probable that he fully appreciated the advantages which his country might gain from projects of a commercial or strategical nature, such as railways, telegraphs, and mines; but it was his settled conviction that these advantages would be purchased at too high a price by the necessary employment of large numbers of foreigners, whose activities in the country might have amounted to peaceful penetration and menaced Afghan independence.

Habibullah.—Two days after the death of Abdur Rahman his eldest son was recognized as his successor. Habibullah introduced the reduction of taxation, the establishment of a council of state for tribal affairs, and the association of tribal chiefs with provincial governors for the adjudication of tribal cases. He also inaugurated military reforms. He loyally observed the condition regarding the control of the foreign affairs of Afghanistan on which the Government of India had recognized his father as Amir, but on all questions relating to the development of his country's trade and more intimate relations with the Government of India he proved to be as wary and suspicious as his father had been. He consented, indeed, to receive a special mission under Sir Louis Dane, foreign secretary to the Government of India which reached Kabul in Dec. 1904, but the mission failed to obtain any concessions, and the result of its work was merely the confirmation and ratification of existing agreements and the concession to him in the treaty of the title of "Majesty." After the failure of this mission an endeavour was made to remove his prejudices and to enlarge his mind by arranging for him a visit to India, in the course of which he could meet the leading administrators of the country. His acceptance of the invitation was viewed with disfavour by the more bigoted and ignorant of his subjects, but the manner of his reception by Lord Minto in Jan. 1907, and the good will displayed towards him, undoubtedly did much to improve the relations between the two Governments.

By the Anglo-Russian convention signed on Aug. 13, 1907, Great Britain disclaimed any intention of altering the political status of Afghanistan, and Russia declared Afghanistan to be beyond her sphere of influence.

Habibullah, though as suspicious as his father, was more susceptible to modern influences, and among the many mixed blessings of civilization which he introduced into an unappreciative country were motor-cars, telephones, newspapers, a hydro-electric scheme, and the Habibia college, a high school in Kabul, the staff of which was chiefly composed of teachers from India. Many of these were regarded by the ignorant clerics of Afghanistan as inventions of the devil and the seed of infidelity, and it was partly from a sense of the antagonism which their introduction had aroused and partly with a view to conciliating the hereditary enemies of his house that Habibullah treated with great and unusual leniency the Ghilzais and Mangals of Khost, the district lying immediately to the west of the Kurram valley, who in 1912 had been goaded into rebellion by the rapacity of the local governor.

The World War.—On the outbreak of the World War in 1914 the Amir declared his intention of abiding by his agreement with the British Government and maintaining the neutrality of his country, but the entry of Turkey, the chief Islamic power, whose ruler was regarded by many Muslims as their Caliph, encouraged the anti-British party in Afghanistan and induced the Amir to receive a German mission, which contrived to reach his western frontier by way of Persia and entered the country as fugitives, having left in the hands of the Russians their confidential papers and that which was most likely to make them welcome in Afghanistan, their gold. They were admitted to Kabul, but their manners and bearing were not calculated to conciliate their hosts. They were regarded as state prisoners rather than as guests, and, in 1916, becoming apprehensive, on misleading information, of the Amir's intentions towards them, they retired hastily from Afghanistan, and some of them, falling into the hands of the Russians, were treated as prisoners of war. Habibullah preserved his neutrality until the end of the war, and would doubtless have received substantial recognition of his loyalty, in most difficult circumstances, to his obligations, had he not been assassinated on Feb. 20, 1919. His brother Nasrullah Khan, caused himself to be proclaimed Amir, but after a reign of six days was ousted by his nephew, Amanullah, who was recognized by the nobles and people as king. He was unfortunately not strong enough to resist the popular demand for war with Great Britain, regarded as Turkey's chief enemy, and on May 2, 1919, Afghan troops crossed the Indian frontier. Immediate steps were taken to expel them, and British and Indian troops, after encountering some resistance, occupied Dakka, beyond the Khyber; but before the concentration of the British troops was complete Amanullah, brought to his senses by the appearance of the first aeroplane over Kabul, made overtures for peace. Negotiations ended in a Treaty of Peace signed at Rawal Pindi on Aug. 8, 1919, by the terms of which the annual subsidy which the Amir had received since 1879 was discontinued, and Afghanistan was released from the control of her relations with foreign states. A conference at Mussoorie in 1920 prepared the way for the Treaty of Nov. 22, 1921, by which the two Governments agreed to respect one another's independence in domestic and foreign affairs; to recognize existing frontiers, subject to a slight readjustment near the Khyber, and to receive legations at London and Kabul, and consular officers at Delhi, Calcutta, Karachi and Bombay, and Kandahar and Jalalabad respectively. The Afghan Government retains the privilege of importing through India, free of duty, arms and munitions of war; and all restrictions on the export of goods from Afghanistan to British territory have been removed. A trade convention has since been concluded, and one to deal with posts and telegraphs is contemplated.

Russo-Afghan Treaty.—Afghanistan has proved that she may be trusted to control her relations with other states with credit to herself, for she has dealt successfully with three difficult and delicate situations. The first arose from a clause in the Russo-Afghan Treaty of Feb. 28, 1921, permitting the establishment

of Russian consulates at Ghazni and Kandahar—places so remote from the sphere of Russia's legitimate interests that it was obvious that the consulates could serve no purpose but that of facilitating hostile intrigue on the Indian frontier. The British commissioner declined to discuss the terms of a treaty unless Afghanistan annulled a concession so prejudicial to British interests, and she satisfied his demand without dangerously offending Russia. The second arose in 1924, out of the murder of two British officers by two Afghan subjects within a mile of the Afghan frontier, and this outrage was closely followed by the flight into Afghanistan of some ruffians who had murdered an English lady and abducted her daughter. The third, which nearly led to a rupture with Italy, arose from the shooting of an Afghan policeman by an Italian named Piparno in the employ of the Afghan Government. The procedure at the trial was prejudicial to the accused and violated the principles of at least one school of Muslim jurisprudence by ignoring the prior settlement of the case, with the cognizance of the State, by the payment of blood-money to relatives. In these circumstances the execution of Piparno aroused a dangerous feeling in Italy, but Amanullah's success in handling this and the other two cases cited proved that he had inherited a large share of his grandfather's strength of character and political sagacity.

In opening up his country to Western civilization Amanullah departed from the traditional policy of his dynasty, and he was in many respects so far more enlightened than the generality of his subjects as to be in some danger of alienating them, as in the case of his scheme for female education, which led the clerics to foment the dangerous rebellion which broke out in Khost early in 1924, and was not suppressed until the following spring.

Amanullah seemed to be making some progress in overcoming the ignorant prejudices of his subjects. The establishment of Afghan Legations in Moscow, Berlin, Paris, Rome, Tehran, Angora and London, and the reception of foreign legations in Kabul made them more familiar with the life of the outside world. In addition to a wireless station at Kabul, which is in regular communication with Peshawar and Tashkent, Kabul and neighbouring towns are linked with the Indian telegraph system and it is possible that Kabul may soon be linked, through Kandahar and Herat, with the Russian system. Since 1910 the introduction of motor-cars has had its natural result in the improvement of the roads. Those in the neighbourhood of the capital have already been completed, and the projected roads from Kabul to the Khyber, and from Kabul to Kandahar, and thence to Chaman will influence profoundly the economic and political development of the country. The extension, in 1925, of the Khyber railway from Jamrud to the head of the pass has stimulated trade by this route. The Hindu Kush, with its steep ascents and difficult passes, for the present effectively blocks communication by mechanical transport between Kabul and the north.

The extensive employment of Europeans on technical, educational, and other work can hardly be said to be popular, but its necessity, for the present at least, is gradually coming to be recognized. The wisdom of entrusting the development of the air force and some other essential services exclusively to Russians may well be doubted, but there seemed little doubt of Amanullah's ability to rid himself of Soviet agents should he find himself embarrassed by their intrigues.

Late in 1927 Amanullah left Afghanistan for an extensive tour which included part of India, Egypt, Italy, and England, as well as other European countries. That it should be possible for him to absent himself from his kingdom for so many months without apprehension was evidence of his belief in the loyalty of his ministers and the stability of his throne. A trade convention signed at Kabul on June 5, 1923, provided for three transit routes across British India for the forwarding of goods to and from Indian ports. In 1929 the throne was occupied by Nadir Shah.

AFGHAN LANGUAGE: see PUSHTU.

AFGHAN TURKISTAN, province of Afghanistan, bounded east by Badakshan, north by the Oxus river, north-west and west by Russia and the Hari Rud river, and on the south by the Hindu Kush, the Koh-i-Baba and the northern watershed of the Hari Rud basin. It is 500m. long, north-east to south-west, and averages 114m. in width between the Russian frontier and the Hindu Kush. The area is about 57,000sq.m.—two-ninths of Afghanistan. The population is about 750,000, mainly cultivators in towns and villages, the chief being Mazar-i-Sharif (46,200), the modern supplanter of Balkh. The lowland has much loess and the riverine lands of the Oxus are highly cultivated, but to the west the Turkoman area is waste, and to the south are rough mountains. The people are Persian and Uzbek with Turkoman, Hazara (Mongol) and Hindu elements. Ancient Balkh or Bactriana belonged to the Achaemenian empire. About 250 B.C. Diodotus (Theodotus), governor under the Seleucidae, made himself independent and founded the Graeco-Bactrian dynasties which succumbed to Parthian and nomad movements about 126 B.C. The succeeding Buddhist era has left us huge sculptures at Bamian and the rock-cut toposes of Haibak. Jenghiz Khan laid waste the land; later it belonged for a century to the Delhi empire, then became Uzbek, and in the 18th century came under Ahmad Khan and his son Timur (Durani Afghans). Next the Khanates fell apart during strife between Timur's sons, and the Uzbek khans came under the rule of Bokhara. Under Dost Mohammed (1850-1859) the Afghans occupied the province, and boundary disputes were settled (1873) by the Anglo-Russian agreement awarding Andkhui, Shibarghan, Saripul and Maimana to Afghanistan. The Russo-Afghan commission delimited the boundary in 1885.

AFIUN QARAHISAR, the popular name of Kara-hissar Sahib, the chief town of a vilayet in Asiatic Turkey, nearly 200m. east of Smyrna, and 50m. south-south-east of Kutaiah. Population (1927), 102,487. Called Nicopolis by Leo III. after his victory over the Arabs in 740, its name was changed by the Seljuk Turks to Kara-hissar. It stands partly on level ground, partly on a declivity, and above it rises a precipitous trachytic rock (400ft.) on the summit of which are the ruins of a Byzantine castle. The town is an important centre of trade. Opium in large quantities is produced in its vicinity and forms the staple article of its commerce; and there are, besides, manufactures of black felts, carpets, arms and saddlery. Afiun contains several mosques (one of them a very handsome building). The town is connected by railway with Smyrna, Konia, Angora and Constantinople.

See V. Cuinert, *Turquie d'Asie* (Paris, 1894), vol. iv.

A FORTIORI (Lat. "from a stronger [reason]"), a term used of an argument in which the conclusion is supported by a ground that is stronger than another that has already been accepted, or is commonly accepted, as sufficient justification for asserting the predicate of the conclusion of that kind of subject. For example, if in a right-angled triangle the side opposite the right angle must be greater than either of the other sides (because the right angle is greater than either of the other angles),

"how much more so" (*a fortiori*) must this be the case in an obtuse-angled triangle (which is even greater than a right angle).

AFRANIUS, LUCIUS, Roman general, lived in the times of the Sertorian (79-72 B.C.), third Mithridatic (74-61 B.C.) and Civil Wars. In 60 B.C., chiefly by Pompey's support, he was raised to the consulship. In the following year, while governor of Cisalpine Gaul, he obtained a triumph, and on the allotment of Spain to Pompey (55 B.C.), Afranius and M. Petreius were sent to govern it as legates. On the rupture between Caesar and Pompey they were compelled, after a short campaign in which they were at first successful, to surrender to Caesar at Ilerda (49 B.C.), and were dismissed on promising not to serve again in the war. Afranius, however, joined Pompey at Dyrrhachium, and at the battle of Pharsalus (48 B.C.) had charge of Pompey's camp. Despairing of pardon from Caesar, he went to Africa, and was present at the disastrous battle of Thapsus (46 B.C.). He was afterwards taken prisoner and handed over to Caesar, whose veterans put him to death.

See Hirtius, *Bell. Afric.*, 95; Plutarch, *Pompey*; Dio Cassius xxxvii, xlii-xliii.; Caesar, *B.C. i.* 37-87; Appian, *B.C. ii.*; CAESAR and POMPEY.

AFRANIUS, LUCIUS, Roman comic poet, flourished about 94 B.C. He dealt chiefly with everyday subjects from Roman middle-class life, and tells us that he borrowed freely from Menander and others.

See Horace *Epp. ii.* 1.57; Cicero, *Brutus*, 45. *de Fin.* i. 3; Quintilian x. 1. 100; fragments, about 400 lines, in Ribbeck *Scaenicae Romanorum Poesis Fragmenta*, ii. (1898).

AFRICA, the name of a continent which is the largest of three great southward projections of the main land-mass of the earth's surface, joined to Asia by the isthmus of Suez, 80m. wide. From its northern extremity, Ras ben Sakka, a little west of Cap Blanc in 37° 21' N. to the southern, at Cape Agulhas, 34° 51' 15" S., it is about 5,000m. long while west to east it is about 4,600m. from Cap Verde, 17° 33' 22" W., to Ras Hafun, 51° 27' 52" E. Length of coastline is 16,100m. for a mainland area of 11,262,000 square miles.

GEOGRAPHY

Africa is largely a plateau, broken and elevated in the south and lower towards the north, with fold mountains adhering to the northern flank, and it thus contrasts very strikingly with Europe and Asia in which fold mountains of successive series in diverse stages of denudation occupy a large proportion of the surface. The mean elevation of Africa is about 2,000ft., that of Asia 3,117ft. Asia has much quite low as well as very high land. Africa, as a plateau, has little at either extreme and in particular the land over 10,000ft. in Africa is merely small groups of peaks.

The high southern part of the plateau reaching north almost to lat. 10° S. has sharp slopes around its edges on the west, south and east, with a narrow coastal plain below, broadening in the north-west and especially the north-east in Angola and Portuguese east Africa respectively. Towards the south this plateau has a high rim, over 6,000ft. above sea near Windhoek in the west and in Basutoland on the south-east. The southern edge is stepped, with the Nieuwveld range above the Great Karroo, the Little Karroo as the step next below and the coastal plain next below that. Within the high rim are considerable areas of centrally placed lower land, the South Kalahari in the south, the depression draining into Lake Ngami (now practically dry) and the Barotse-land depression, but all keep above the 1,500ft. contour and each is a local depression in a table-land most of which is at more than 3,000ft. above the sea. Generally speaking the plateau-edge dips down, with a small coastal ledge, into fairly deep water, but towards the Cape of Good Hope there is a fair area of shallow water off-shore.

The steepness of the edge of the plateau is important as a determinant of the character of the rivers, long sections of which flow in deep slots cut back into the plateau from its edge. The Orange river is fed from the rains that fall on the Drakenberg range and flows west through lands of drought; the Limpopo and Zambezi, the two largest on the east flow out to the broad sandy alluvial flats of Portuguese East Africa and the slot-like character

of a large part of the Zambezi-channel is generally known from the occurrence of the famous Victoria Falls. In the south-west the Zambezi system interlaces with that of the Taukhe or Tioghe and receives surplus water from it at times. The rest of the Taukhe water loses itself in the swamps and salt-pans of the former Lake Ngami basin. The lower parts of the three great rivers have contributed to the lowering of considerable areas of the plateau below the 3,000ft. level. The Zambezi river, about 2,000m. long, drains an area of half a million square miles, the Orange river, about 1,300m. long and with a drainage area of about 170,000sq.m. but more than that amount must be added if we define the basin orographically and so include in it larger waterless tracts. Towards the north this southern plateau tends to run rather higher and there is a continuous belt of highland across the continent from the coastal plain on the west to Lake Nyasa on the east, in which region the typical form of the southern plateau is interfered with by important rifts to be considered next. Allowing for complexities the southern plateau of Africa is thus essentially an elevated surface with still higher edges for the most part and with, also, considerable depressions, usually deserts in character, near the median north to south axis of the plateau. North of this southern plateau, on the west, is the basin depression, largely floored by younger rocks and now occupied by the Congo and its numerous feeders. The basin is almost enclosed by land over 1,500ft. in height, for the main river escapes through a deep cut between the hills out to sea; there is general agreement that the basin is a depression in the original plateau surface that has been an inland sea. To the east of the basin are series of physical features that together constitute one of the major physical problems of the earth's surface. They are collectively designated the Rift valley system and have been the subject of much discussion, for which reference may be made especially to the files of the *Geographical Journal* (London, especially 1916-21) and to Krenkel *Geologie Afrikas* (1925). In this region in later tertiary and early Pleistocene times great movements occurred and earthquakes are still a feature. Often a block has sunk between parallel fractures and thence has come the name of Rift valley. A western rift may be traced from Lake Nyasa via Tanganyika and Lake Albert to Gondokoro. Many of the fractures run either north-west to south-east (the so-called "Erythraean" direction) or, in the north, north-east to south-west (the "Somali" direction). A middle rift line goes north-north-east from Nyasa via Lake Nai-

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

NATIVES OF WEST AFRICA ENGAGED IN MAKING SPOONS IN THEIR TRADITIONAL MANNER

vasha to Lake Rudolf, with branchings and changes *en route*; though its general direction is north to south, its component fractures are generally north-west to south-east and north-east to south-west, with some north to south ones in the north. The easterly rift line is less important and goes on the whole north-eastwards from about the middle of Lake Nyasa. In the floors of the rifts lie the long narrow lakes, Nyasa 1,645ft. above sea-level but with a maximum depth of 2,580ft. so part of its floor is over 900ft. below sea-level, Tanganyika, also very deep and normally 2,624ft. above sea-level but this level is so variable that the outflow from Tanganyika is quite intermittent, and Rudolf at only 1,180ft. Some other lakes are small; that of Naivasha is over 6,100ft.

Many portions of these lakes have sharp walls and are obviously filling depressed zones. The western rift is the youngest and sharpest; the most important movements may have been as late as the Pleistocene period. The rifts all show volcanic activity which is most marked along the eastern sides of the middle one, where occur the great peaks of Kenya (17,007ft.) and Kilimanjaro, on which Kibo peak (19,321ft.) has long been held to be the culmination of Africa but Nilsson (1927) claims to have found points on Kilimanjaro 13ft. and 17ft. higher, respectively, than the highest previously known. Ruwenzori, on the eastern side of the western rift is 16,794ft. high and has a block structure apparently with faulted sides; interestingly enough it is in about the same latitude as the other great peaks mentioned and they are all on a belt of land, higher than most of the flanking territory, that stretches from the volcanic Cameroons (*v. inf.*) to the east coast. This cross-line scheme is noticeable in great basins (Niger, Chad and Bahr-el-Ghazal) to the north-west and is evidently of some importance in the story of the deformations that Africa has undergone.

It seems clear that at Lake Albert there was faulting on a large scale both before and after the country was arched up into a wrinkled dome while, farther east, the middle rift may be connected with faulting near the median axis of a long arch. Faulting of domed and arched structures, supplemented by vulcanicity on a large scale, both occurring so recently as to leave features extremely sharp, are thus the characteristics of the country. Between the arched areas of Lake Albert and the middle rift in a downfold lies Lake Victoria of area approximately 26,000sq.m. and more or less rectangular but fractures determine only a small part of its outline and its shores are not high-cliffed. Unlike the rift lakes, it is less than 50 fathoms deep. It is at 3,720ft. above sea-level.

It is well known that the zone of fractures extends northwards marking the east and west edges of the Abyssinian highland, the series of cliff lines bordering the Gulf of Aden and the Red Sea, and the rift lines along the Gulf of Aqaba to the Dead Sea and the Jordan valley. All through this zone one finds systems of parallel fractures and a considerable number are north-west to south-east, others are north-east to south-west, others apparently north to south.

The relations of land and water, both inland waters and the ocean, have naturally varied a lot with the great changes of land levels, but apparently since present levels were reached, and therefore probably well on in the Pleistocene period, lakes of immense size existed in the rift valleys of East Africa. Shore lines 600ft. above present water-levels have been traced over long distances and there is not much doubt that during the major glacial phases of the Pleistocene ice age in Europe the mountains of East Africa were glaciated much farther down than at present.

The northern extension of the rift system to Lake Rudolf and beyond it north-westwards to the lowlands of the White Nile divides east Africa from Abyssinia and Somaliland. The latter is a plateau sloping south but broken sharply on the north, where a steep slope marks the coast of the Gulf of Aden, and less sharply on the south-east to the Indian Ocean as well as on the south-west towards the Juba river basin which may be described as a widening of the coastal plain. Socotra is essentially a broken off projection of Somaliland. Abyssinia on the other hand is a remarkable mountain land bounded east and west by great fractures of remarkable sharpness giving steep cliffs down to the Red Sea and to the White Nile lowland. The rift system of the Red Sea and that of the Gulf of Aden both enter into relationship with an Abyssinian rift which runs from the sea to Lake Rudolf and divides Abyssinia from Somaliland. Abyssinia differs entirely from any folded mountain range; it is a high and deeply dissected block full of evidences of volcanic activity and provided with powerful rivers, feeders of the White Nile (Sobat, etc.) the Blue Nile and the Athara, indicating its high (largely summer monsoonal) rainfall. It lies for the most part more than 5,000ft. above sea-level and reaches up to nearly 15,100ft. at Ras Dashan in the north. Lake Tana (Tsana) in the highlands is actually 5,690ft. above sea-level.

The Nile may be said, in a way to begin as the Kagera, the chief feeder of Lake Victoria. It leaves that lake on the north and after passing through the lake swamp of Kioga it goes to the north-eastern end of Lake Albert. Issuing again from the northern end of that lake, it emerges in due course from the rift system into a great flat area less than 1,500ft. above sea-level and framed by higher land save in the north-east and giving so little fall on the river that it becomes obstructed by floating vegetation. It is noteworthy that this upper Nile basin, the Lake Chad basin and the main Niger basin, all more or less enclosed, are nearly in the same latitude, with the still more enclosed basin of the Congo to the south. Basins of this kind are thus a marked feature of the geography of the old block of Africa. After the Nile (Bahr-el-Jebel) has received the Sobat from the east it flows north through increasingly barren country into a slot cut in the great desert. The transition from the fertile slot up the, often steep, slope to the desert plateau is a very sharp one and the river has no tributaries in its desert section. It thence follows that, though the Nile is 4,037m. long from the Kagera source to the sea, its basin-area is only 1,107,227sq.m., whereas the Congo, rather under 3,000m. long but very rich in tributaries, has a basin area of about 1,425,000 square miles.

North of the Congo basin one may go from the Gulf of Guinea across to the extreme east without touching a point less than 1,500ft. above sea. This rise or swell of the land surface has, on its north-west border, the high line (north-east to south-west) of the Cameroons, apparently an old mountain structure rejuvenated by volcanic outpourings. On this line stands the great peak of the Cameroons (13,370ft.) at the corner of the Gulf of Guinea, and it is continued into the sea giving the island of Fernando Po (Spanish) and those of S. Thomé and Príncipe (Portuguese). On Fernando Po, Clarence Peak is over 9,000ft. high.

North of the Gulf of Guinea the land soon rises above the 600ft. level and towards the west there is a fairly marked slope up from the sea to over 1,500ft. above its level, the slope faces south-west and above it towards the north is a patch above 3,000ft. in height while one small area near the northeast border of Liberia reaches nearly 10,000ft. This region, with a heavy, monsoonal, summer rainfall is the birthplace of the feeders of the Niger. Thence that river flows north-east demonstrating the general slope of the land down to the Sudan and Sahara, then east and south-east and south to reach the gulf in the lowland between the eastern end of the West African coastal edge and the highland of the Cameroons. Its length is about 2,600m. and basin-area about 800,000 square miles.

Between the main Niger basin and that of the Bahr-el-Ghazal and White Nile lies a basin of internal drainage with the shallow, shrinking Lake Chad in its southern half and a depressed area with some swamps in the north-east. Lake Chad is about 850ft. above sea-level, and receives drainage from the south-east and west. The other depressed area is, in parts, less than 600ft. above sea but the drainage to it is of very small account. North of the Niger and Chad basins is the immense arid belt of the Sahara. It reaches the Atlantic along a low practically waterless coast 1,000m. long from the mouth of the Senegal to the streams of the Atlas. The western part of the Sahara is generally low and has no heights reaching 1,500ft. but in the northern centre is the Ahaggar plateau, connected with the eastern end of which are north-west to south-east lines of higher land one going north-west to the Gulf of Qabes and one south-east crowned by the Tibesti highlands. Eastward, heights diminish again but there is practically a continuous cliff edge along the Nile slot on both sides and the continuation of the desert plateau on the east stands for the most part more than 1,500ft. above sea with a considerable area over the 3,000ft. line.

The desert has large sandy areas especially in the west with regions of stony desert (*hammada*) in the northern centre and a good deal of stony desert to the east. A number of oases break the monotony of the desert, some being north of Lake Chad; some of the land around the Tibesti highland (reaching 8,000ft.) also gets more moisture and has a population aggregated in certain centres. Wadis from the Ahaggar plateau and elsewhere in the desert are

interesting evidences of a former greater rainfall and from a study of animal remains as well as of finds of human implements it seems that the Sahara was more or less a grassland during some phases at any rate of the early ages of man. The probability is that periods of greater rainfall in the Sudan more or less coincided with periods of Pleistocene glaciation in Europe. The desert area is estimated at 3,500,000 square miles. The Nile slot cuts the desert without modifying it appreciably, and opens out north to the famous delta west of which the coast is not high save in the Barca or Cyrenaica plateau which reaches 1,500ft. not far from the sea.

The Atlas range, the north-western part of the continent, is orographically a part of the mountain arcs that frame the basins of the western Mediterranean. It reaches a height of 14,000ft at Bu Uriul and Ari Aiaschi and runs, generally, east-north-east to west-south-west. The eastern half has the Tell Atlas on the north and the Sahara Atlas on the south side with the plateau of the Shotts, several lakes without outlets, between them. The western region has the Mid Atlas continuing the first and the Great Atlas continuing the second; the Anti Atlas is parallel to and south of the Great Atlas. To the north of the Mid Atlas the separate coastal mountain range of Er Rif curves north-west to the Strait of Gibraltar beyond which the curved high line is continued in the Sierra Nevada of southern Spain.

South of the eastern ends of these highlands is a more or less east to west line of low land containing the Shott el Jerid (about 52ft. above sea-level) and the Shott Melrir (nearly 100ft. below sea-level) both without outlet. Africa is remarkable for the extent of land, 3,750,000m. in basins of inland drainage.

Africa is singularly poor in islands. Madagascar 229,820sq.m., is one of the large islands of the world (smaller than New Guinea and Borneo); it is separated from Africa by the rather deep Mozambique Channel and in structure it resembles Africa. Biologically it has links both with Africa and with the East Indian archipelago. Socotra, east-north-east of Cape Guardafui, a continuation of the Somaliland plateau is the only other African island of any size. The Canary and Cape Verde archipelagoes of the north-west and the Comoro archipelago of the east are volcanic (but pebbles of continental, or plutonic, material have been sent to Europe from Anjovan, one of the lesser Comoro Islands); the Seychelles are a continental remnant. There are coral islets between the Comoros and the Seychelles. Mauritius, Reunion and Rodriguez, the two last entirely, the first mainly volcanic, lie in the Indian Ocean east of Madagascar; Ascension, St. Helena and Tristan da Cunha in the south Atlantic far to the west. (X.)

CLIMATE

Extending from latitude 37° N. to 35° S., the greater part of Africa lies within the tropics, and except on mountains and plateaux the average annual temperature is high, ranging from 62° at Cape Town to 86° at Massaua on the Red Sea. On the other hand there are great extremes of rainfall; in the Egyptian desert appreciable falls occur only once in a number of years, while the western slopes of the Cameroon mountains are among the wettest parts of the world, Debundscha at the foot of Cameroon Peak having an average of 369in. a year. Africa may be conveniently divided into five climatic divisions, of which four run roughly parallel with the lines of latitude, while the fifth occupies a large part of the eastern coastal districts. On either side of the equator is a belt of heavy rainfall which is distributed fairly uniformly throughout the year, but with a tendency for April and October to be the wettest months, those following the annual passage of the sun across the equator. This belt roughly coincides with the Congo valley and Gabon. Northwards the first rainy season is retarded into May and June, while the second rainy season is advanced into September and August, giving a long dry season, a principal wet season, a short dry season and a secondary wet season which is not much inferior in intensity to the first. In latitude 8° or 9° N. these two rainy seasons coalesce into one wet season lasting from May or June until September, while the rest of the year is dry; at the same time the total rainfall decreases. North of 15° N. the rainfall is small and irregular and

we pass into the belt of desert which includes the Sahara and Sudan. This extends to the Mediterranean in the north-east, but in the north-west there is a coastal strip in Algeria and Morocco which has a long dry summer but an appreciable winter rainfall and forms part of the Mediterranean climatic province.

In South Africa there is a similar succession, the April rainfall maximum of the equatorial belt advancing into March and February, while the October maximum is retarded into November and December, until the two coalesce into the summer rainfall region of the southern hemisphere, which includes Angola and southern Rhodesia. South of this is the Kalahari desert, the counterpart of the Sahara, while in the extreme south-west is a small area round Cape Town with a dry summer but appreciable rainfall in winter (April to September). This zonal division does not apply to eastern Africa south of the equator, which has summer monsoon rains and a winter dry season over its whole extent.

A RAIN-MAKER, AN IMPORTANT MEMBER OF WEST AFRICAN COMMUNITIES, WITH THE REQUISITES OF HIS MAGIC

The Equatorial Rainfall Belt.—This region includes the greater part of the Congo basin above Leopoldville, Gabon, Cameroon and the coast of Nigeria as far as the mouth of the Niger. Its characteristics are uniformly high temperature and humidity, a large amount of cloud and a rainfall generally exceeding 60in. a year and rarely falling below 2in. in any month. The temperature is rarely extreme, and probably many parts of the region have never reached the Greenwich maximum of 100°, but on the other hand the temperature rarely falls below 60° on the low ground. The annual average may be taken as 80°, rising to 87° during the day and falling to 73° at night. The hottest months generally fall in the early part of the year, while July and August tend to be coolest, but the annual range is rarely as much as 10°. The relative humidity averages 80%, and this continual moist heat is very enervating to Europeans. The greater part of the region is densely forested.

Savanna Belts.—North and south of the equatorial rain forest is a zone of moderate rainfall, the whole of which falls in a short summer rainy season, while the remainder of the year is dry. These belts may be regarded as extending as far as the isohyet of 20 inches. The northern belt includes Senegal, Bathurst, Sierra Leone, the Gold Coast, Dahomey, the greater part of Nigeria, the Sudan and Abyssinia. The rainfall varies greatly, rising to as much as 154in. a year at Sierra Leone, but even there the months of December to March are almost rainless. The drier parts are occupied by open grass-land but the wetter areas are forested. The rainy season from May or June to September inclusive, in spite of being summer in the astronomical sense, is the coolest part of the year, the temperature being kept down by the great cloudiness and heavy rainfall. This season is unpleasant because of the high humidity, the small daily range of temperature and the frequent thunderstorms and tornadoes, especially at the beginning and end of the season. The prevailing wind is south-westerly at the surface, but is very light; at a height of a few thousand feet the wind becomes north-easterly, and the thunderstorms advance from the north-east. From late October until the end of February is the most pleasant season, with hot days but cool nights, dry air and clear skies; the prevailing wind is north-easterly except on the coast, where sea-breezes occur during the day. Over the interior the wind is often laden with penetrating fine dust (Harmattan wind). In March, April and the beginning of May, the temperature is very high, maxima sometimes exceeding 100° even on the coast, and reaching 110° in the interior. The humidity of the air is still low but is rising steadily, and the wind is light and variable. The rainfall of the Abyssinian plateau is of great importance as the source of the annual Nile floods, and so of the fertility of Egypt. The annual rainfall of

Addis Ababa averages 50in., but more than three-fifths of this amount falls in July, August and September, while October to January inclusive are almost rainless. In spite of the position of Abyssinia near the eastern margin of Africa, it is believed that most of the moisture which falls as rain is derived from the Atlantic ocean, and is carried across the whole width of the continent by the south-west winds, and that only a comparatively small part of the rainfall is derived from the Indian Ocean. The southern savanna belt includes Angola and Rhodesia; the climate is generally similar to that of the northern belt, but the summer rainy season occurs from December to February. The rainfall nowhere exceeds 60in. and owing to the generally high elevation the climate is comparatively pleasant and healthy. The amount of cloud is comparatively small, and the lowest temperatures occur in winter and not, as in the north, in the rainy season.

Deserts.—The greater part of Africa north of 16° N. is occupied by an arid climate which gives rise to the deserts of the Sahara and Egypt. The rainfall is less than 10in. a year, and over a large part of the area is probably less than an inch, being confined to a few drops once or twice a year and isolated heavy falls at intervals of many years; under these conditions the term "average" has no meaning. The temperature is very high in summer, the average in July exceeding 90° over a large part of the interior; it remains very hot from April to September inclusive, but the winter months are relatively cool. The daily range of temperature is very great, exceeding 30° at many places; for example at El Obeid in the Anglo-Egyptian Sudan in January the mean daily maximum is 86° and the mean daily minimum 52°, and frosts are occasionally experienced. Very high maxima are recorded in summer, exceeding 110° on the coast and 120° in the interior, while at Azizia, in Tripoli, a shade temperature of 136° has been recorded, the highest known on the earth's surface. The air over the interior is dry, less than 40% average humidity for the year, and figures of 2 or 3% have been recorded. On the coast special conditions prevail, which will be referred to later. The amount of cloud is very small, generally less than one-fifth of the sky covered, while in parts of the Egyptian desert no cloud is seen for months together. The winds are generally light and irregular over the Sahara, but dust storms, sand pillars and other local violent winds occur. In the Nile valley the prevailing wind is southerly from November to February and northerly from April to September and reaches considerable strength in the midsummer months, greatly moderating the temperature; occasional very hot, dry, dust-laden southerly winds are known as the Khamsin; these are very unpleasant, especially when accompanied by sand storms. Similar winds from the desert occur also under local names in Tripoli, Tunis and Algeria; they frequently cross the Mediterranean to southern Italy as the scirocco. A severe form is the dreaded simoom or samun, a hot blast of air (125° or more), often accompanied by heavy clouds of dust or sand. Land and sea breezes are well developed on the coast of Tripoli, Tunis and Algeria, but not of Egypt. The corresponding desert of southern Africa, the Kalahari, is of much less extent, being limited to the western half of the continent, and the heat and dryness are not so excessive as in the Sahara.

The climate of the coast of the Red Sea and Gulf of Aden is peculiar. The rainfall is exceedingly scanty, the sky almost cloudless, and the temperature very high, but this is associated with an abnormally high humidity, the moisture being derived from the warm waters of the Red Sea, which reach 90°. The highest known temperature of the wet-bulb thermometer, 100°, has occurred at Kamaran island and Berbera; this moist heat is very unpleasant. Where the Sahara and Kalahari meet the Atlantic, different conditions occur; here the presence of cold currents makes the surface of the sea very cold, while the land a few miles inland is very hot; these regions have a very small rainfall, clear skies but frequent fogs over the sea, and a moderate temperature which changes very little throughout the year. The rainfall of the South African west coast from 17 to 28° S. is less than an inch a year.

Mediterranean Climate.—Morocco, northern Algeria and northern Tunis have pleasantly mild, rather rainy winters and

long, hot, dry, almost cloudless summers. The annual rainfall averages about 30 in., but is very variable. The mean temperature is between 50° and 60° in January and about 80° in July and August; the daily range is about 15°. A similar climate is found over a small area near Cape Town, which has a temperature ranging from 55° in July to 70° in January and February, and a rainfall of 25 in. falling mainly from May to September inclusive.

Eastern Africa.—Kenya Colony, Tanganyika, Uganda, Nyasaland and Portuguese East Africa have an equable climate with a temperature between 75° and 80° near sea-level and a rainfall of 30 to 60 inches. There is generally a fairly well-marked rainy season; near the equator this occurs in April and May with a minor rainy season in November and December, but further south there is only one rainy season, falling in summer. Thus at Zanzibar the rainiest months are April, May and November, in that order, and at Nairobi, April, November and May, but at Lourenço Marques in 26° S., January and February. The dry season or seasons are not so extreme as in West Africa; months entirely without rain are rare and the relative humidity remains fairly high throughout the year. The prevailing winds are easterly. Thunderstorms are very frequent during the rainy season, recurring with great regularity almost every afternoon. The low-lying coastal areas are enervating and in places unhealthy, but large parts of the interior, including the whole of Uganda, form plateaux with an elevation of several thousand feet, and as the average temperature decreases upwards at a rate of about 3° per 1,000 ft., these uplands are much cooler and more bracing than the coastal regions, while their distance from the sea makes them somewhat drier except on slopes directly exposed to the rain-bearing easterly winds. These plateaux are rather more suitable for European habitation than the coastal areas. Natal and the eastern parts of the Cape Province have warm, rainy summers, with a temperature of 70° to 75°, and moderately cool winters, relatively dry but very seldom rainless. The annual rainfall is between 30 and 40 in.; the average July temperature is 63° at Durban and 59° at East London, but over the high ground of the interior frosts are sometimes experienced in winter. This is one of the finest and healthiest climates in Africa. (C. E. P. B.)

FAUNA

Africa, together with the Deccan and West Australia as well as Brazil, forms part of the old continental mass of Gondwanaland, whatever view one may take of the process of separation of each from the others. Gondwanaland seems to have persisted through much of the Mesozoic era, during which these southern lands were separated from the northern ones by the broad sea of Tethys, along which later uprose the great fold mountain ranges that stretch from the Pyrenees to the Malay. The southern lands thus show resemblances in their forms of life that are due to these old links. Another factor of the history of life within them is the stability of their conditions as contrasted with the wide variations that have occurred in the orography and climate of the northern lands. Those wide variations have been reflected in evolutionary changes among living things and thus the northern lands have become in a large measure the homes where new forms are born, while the southern ones are largely refugees of early strays from the north, or places where certain types immigrating since connections were made have had a great career. The Sahara desert-barrier is largely a modern (post-glacial) hindrance to immigration of animals, the Rift system a partial but serious hindrance also relatively recently established.

The isolation of Africa is far less than that of Australia, and, whereas Australia retains the two lowly egg-laying mammals (*Ornithorhynchus* and *Echidna*) and is the great home of the marsupials, and of no other truly native mammals save bats, an indication of its long separation, Africa retains neither the egg-laying mammals nor the marsupials. The lowliest order of truly placental mammals, the so called Edentata, absent from Australia, occurs in South America, Africa and south-east Asia. Its great home is South America, but the armadillo (Cape ant-eater) is peculiar to Africa and *Manis* (the scaly ant-eater) has species both in Africa and in south-east Asia. It is an interesting fact that the order,

though an ancient one is absent from Madagascar. The primates offer a contrasted distribution. Among them the lemurs are ancient forms of known fossil from the northern lands but now surviving in Africa, Madagascar and south-east Asia; Africa has many more forms than south-east Asia and Madagascar many more still. From the lemurs have descended monkeys and apes; the platyrrhine monkeys are American, the catarrhine, African and Asiatic, including, among anthropoid apes, the orang-utan and the gibbon of south-east Asia and the gorilla and chimpanzee of intertropical Africa. It is generally thought that the survival of lemurs in Madagascar is a result of its separation from Africa before the great carnivores had spread thither. The absence of elephants, rhinoceros and anthropoid apes from Madagascar is noteworthy. The most important African carnivore is the lion, also found in parts of Arabia, Persia and western India and formerly more generally distributed in south-west Asia and north-east Africa until man restricted its range. The leopard (panther) and hyena are the other large carnivores. Madagascar has very primitive carnivores only, one of which was formerly said to be closely related to a West Indian form though the resemblances seem better interpreted by the fact that both are ancient types. The African elephant is a species distinct from the Indian one; the distribution of the genus was of course far wider until postglacial times. The hoofed animals of Africa are of some interest. Of even-toed forms Africa alone preserves the hippopotamus which ranged widely in northern lands until a late phase of the ice age; remains of a small hippopotamus species have been found in Madagascar which also possesses a river hog (*Potamochoerus*). It is thought that they may have swum across from Africa before the separation between continent and island became very marked. The giraffe and okapi are another family of hoofed animals found in East Africa only. The rhinoceros has east African and south-east Asiatic species. The single humped camel is now a feature of the steppes and deserts of north Africa but only as a domesticated animal introduced from Arabia. Deer are absent from Africa save for a few forms in French Africa, north of the Sahara, just as bears and wolves do not occur south of the desert. On the other hand the immense warm African grasslands are overrun by many antelopes, and the zebra and formerly the quagga. Africa thus, along with a number of old fashioned forms has several relatively new fashioned ones, but the absence of true cattle, pigs, goats, sheep and camels until man brought them is a striking fact. Of the genus *Bos*, nevertheless, South Africa possesses a representative in the Cape buffalo (*Bos capensis*). Africa has many birds peculiar to it but we need only notice the ostrich family of birds that run over grassland and desert border; extinct running birds of great size (*Aepyornis*) lived in Madagascar apparently not very long ago. Some African reptiles (e.g. *Amphisbaena*) appear closely related to South American forms, others to those of northern lands, the abundance of crocodiles is a feature and so are the chameleons, which especially abound in Madagascar. The python and puffadder are notable among African snakes. Monitor lizards, abundant in Africa and elsewhere, have not reached Madagascar. The Amphibians of Madagascar include several species also found in south-east Asia and this may be a result of an ancient land connection, and analogous arguments could be given concerning the land snails. Africa has the disastrous fate of being the one home of the tse-tse fly. (X.)

FLORA

The character of the vegetation of Africa is largely determined by the distribution of heat and moisture coupled with the great range in altitude. Phytogeographically the continent may be primarily divided into three sections: (1) a northern extratropical region, bordering the southern shores of the Mediterranean and gradually fading into the northern Sahara desert with a very scanty flora; (2) a tropical African region, bounded approximately on the north by the Tropic of Cancer; and (3) a South African region, reaching as far north as the Limpopo, Lake Ngami and southern Angola. According to Thonner (*Fl. Pl. of Africa*, 1913), there are in Africa about 3,712 genera and over 40,000 species of flowering plants, a number constantly being added to.

The Northern Area.—The northern area contains a considerable proportion of genera and species common to the south of Europe, besides a large number of endemics in and south of the Atlas mountains and in Morocco. In the Atlas mountains the Atlantic cedar (*Cedrus atlantica*) is a characteristic tree, and is very closely related to species in Asia Minor and the western Himalayas, some authorities having considered them all to be forms of one variable species. The flora of Morocco is related to that of the Canary islands, whilst the somewhat meagre indigenous vegetation of Egypt is largely the same as that of Palestine and Persia.

The tropical African flora may be roughly divided into four regions: (1) a northern desert or semi-desert region; (2) a savannah region; (3) a high mountain region; and (4) the tropical rain forest. The first type is characterized by a very scanty rainfall, and its flora consists largely of plants which are short-lived, such as annuals, or those specially adapted to resist long periods of drought. These include the date-palm (*Phoenix dactylifera*) which grows where other vegetation is practically non-existent. The transition from the semi-desert to that of the savannah is usually gradual with an increase in annual rainfall and pronounced wet and dry seasons. In the savannah the low, thorny bushes of the desert are replaced by scattered trees and shrubs, giving the country a park-like appearance, with an undergrowth of grasses and herbaceous flowering plants, including numerous annuals and species with underground root-stocks. This vegetation is typical of the elevated plateau-region which occupies a large portion of the continent. Characteristic trees are the baobab (*Adansonia digitata*), the shea butter tree (*Butyrospermum Parkii*), *Anogeissus Schimperi*, *Azvelia africana*, *Entada sudanica*, *Parkia filicoidea*, the fan-palm (*Borassus flabellifer*), etc.

In general it may be stated that the desert type is steadily encroaching on the savannah, which in turn is gradually penetrating the northern limits of the forest region, a condition resulting from a combination of desiccating winds during the prolonged dry period and of human agency (shifting cultivation and burning of the grass). In the drier parts of the savannah, for example in the eastern Sudan, large areas are covered by species of thorny acacia, including *A. arabica*, producing gum-arabic. In somewhat less arid but similar country farther south, in Rhodesia, south-east Belgian Congo and parts of Angola, another leguminous genus, *Brachystegia*, is very plentiful, and forms almost pure low forest, whilst in the drier semi-desert areas of south Angola and Damaraland a unique example of the vegetable kingdom, *Welwitschia mirabilis*, is found. In the savannah and neighbouring forest regions there are numerous plants with edible fruits and not a few poisonous plants such as species of *Dichapetalum* (*Chailletiaceae*), the arrow-poison (*Akokaanthera*), *Lasiosiphon Kraussianus*, *Strophanthus*, etc.

The high mountains capping the savannah region, such as the Cameroon mountains, Mt. Elgon, Mt. Kenya, Mt. Ruwenzori, Mt. Kilimanjaro, etc., carry a flora of great interest. On one or other of these mountains it is possible to traverse almost as varied a succession of types of vegetation as might be encountered in a journey from the equator to the vicinity of either of the poles. Many of the genera found on their slopes are represented elsewhere only in the temperate regions of the northern or southern hemispheres. Some of the better known examples are berberis, cornus and anemone, whilst outliers from the Cape region occur, such as *Protea*. The weird forests of tree-groundsels (*Senecio*) and the giant species of lobelia are characteristic features of the East African mountains.

The evergreen forest occupies mainly the low-lying country with a high rainfall distributed throughout the year, and extends in an ever-widening belt from the colony of Sierra Leone to the Cameroons, whence it spreads out over a great part of the Belgian Congo and the Gabon as far as the Victoria Nyanza. This forest sometimes penetrates for a considerable distance into the savannah regions along the banks of rivers. It is particularly rich in endemic species of trees, shrubs and woody climbers, some of which are of great commercial value. The most important timber trees are the African mahoganies (*Khaya*, *Pseudocedrela*, *Entandrophragma*, etc.) and numerous trees of the families Caesalpini-

aceae, Combretaceae, Simarubaceae and Euphorbiaceae. Amongst ornamental shrubs the numerous species of *Mussaenda* (*Rubiaceae*), with enlarged, brightly coloured calyx-lobes, and the brilliant-flowered combretums, are conspicuous. The silk-cotton or kapok tree (*Ceiba pentandra*), with its enormous buttressed trunk, often attains gigantic proportions, whilst in West Africa especially the valuable oil-palm (*Elaeis guineensis*) is abundant. As many of the peculiar genera found in this primeval forest, especially in the Cameroons and Gabon regions, are also found in the Guianas and Brazil on the opposite side of the Atlantic, it seems probable that it is but the remains of a once much more extensive and continuous tract of forest. Apart from Madagascar, the connection between the East African forests and those of tropical Asia is not nearly so marked.

South African Flora.—The South African flora, broadly speaking, consists of two main types: the typical Cape or south-western region occupies a narrow strip within the southern coast line. In some respects it resembles certain features of the Australian flora, the peculiar families Proteaceae and Restionaceae and certain groups of Leguminosae being common to the two areas and rare in other parts of the world. The vegetation of this coastal area is of a marked xerophilous character and bears a superficial resemblance to that of certain parts of the Mediterranean. It is of the so-called bushwood type, and here and there are tracts of grassland. Intermingled with the shrubs are numerous annuals, herbaceous perennials, succulents, etc. Farther inland, between the ranges of mountains, much of the surface is occupied by the "rhenosterbosch," *Elytropappus rhinocerotis* (*Compositae*). True forests occur only towards the eastern part of the region, in the districts of Knysna and Humansdorp, and the trees composing them nearly all belong to tropical genera. In the north-west a few trees of a conifer, *Callitris juniperoides*, are found, being the sole remains of a once extensive forest. The silver-tree, *Leucadendron argenteum*, is now confined to the Capé peninsula, which harbours as many as a hundred species of Erica. Other striking plants in the same district are the brilliant scarlet *Disa uniflora* and the blue *D. graminifolia*, two beautiful ground orchids. There are also numerous species of the geranium family and many beautiful oxalis, large numbers of which are in cultivation.

Of the remainder of the South African regions perhaps the most interesting and remarkable is the Karroo, which occupies a broad belt in the hinterland of the south-western coast region. It is mainly a vast shallow basin which in former times was the bed of a large lake. Its altitude, according to Bolus, ranges from 1,800–2,500ft., the mountains on the northern margin reaching 8,000ft. altitude. The vegetation is of an intensely xerophytic type, being composed mainly of succulents of weird and diverse form, thorn-bushes and numerous plants with bulbous and tuberous root-stocks. Trees are almost entirely absent. The predominant families in this region are *Compositae*, *Leguminosae* and *Ficoideaceae*, the last-mentioned being almost entirely represented

A FAMILY OF MAKALANGA NATIVES
The Makalangas are a branch of the Bantu race of southern Africa—an agricultural people and more civilized than the tribes of the interior

by about 70 species of the genus *Mesembryanthemum* and its segregates. In this area the exotic *Opuntia* from Central America has become a pest.

The upper and Kalahari regions distinguished by Bolus may for convenience be treated as one. Whilst the families mentioned above are still highly represented, the grass family, *Gramineae*, takes a very high place, much of the country being grassland (high veld). Here also there is a considerable influx of families and

genera characteristic of the tropical regions to the north. Amongst the Compositae the everlasting (Helichrysum) are conspicuous.

The south-eastern coast region is bounded on the south-west by the Van Stadens mountains and extends northwards east of the Drakenberg as far as the tropic into which it gradually merges. It is essentially a southerly extension of the tropical flora of East Africa, and contains a large number of such tropical families as Asclepiadaceae, Acanthaceae, Rubiaceae, etc. True rain-forest occurs in Natal. The plants so characteristic of the south-western coast region diminish rapidly northward. Some of the most striking plants in the area are a large tree-euphorbia (*E. grandidens*) and several species of Eucephalartos (Cycadaceae) and numerous species of aloe. Although nearly opposite the island of Madagascar, there is scarcely anything in common between the two floras.

As in the case of the tropical flora, it seems clear, judging by the history of the vegetation, that the climate of South Africa is gradually becoming drier. (J. Hu.)

GEOLOGY

Africa has a simpler geological structure than any other continent, although it has many unique features and formations. It consists essentially of a plateau of which the rocks have not been bent into steep folds by compression since primaevial times, except for a strip in Cape Colony, which was part of an ancient southern continent, and for the Atlas Mountains, which are geologically and biologically European. The continent between these remote chains of fold mountains has undergone no close folding, and most of it has remained above sea level since the time of the oldest known fossils. The margins have been repeatedly reached by the sea, which has submerged the coastal plains and occasionally extended inland up the valleys. The plateau has been fractured and cleft by earth movements which occasioned widespread volcanic eruptions; but the plateau surface has remained a land area on which plants and animals have evolved continuously, subject to the stimulus of changing climate, but never interrupted by submergence. Africa is part of an ancient continent which included most of South America, India and Australia. This southern continent, Gondwanaland, was separated from the contemporary northern land of Eurasia, except for an occasional isthmus, by a sea, the Tethys, which extended from central America through the Mediterranean and across southern Asia to the Eastern Archipelago. The range of this southern continent is best established in Carboniferous times; by the Jurassic its disruption had begun by subsidences which formed the Atlantic and Indian oceans, introduced great changes in its biological relations, and repeatedly caused widespread volcanic eruptions.

The foundation of the continent consists of a vast slab of rocks belonging to the Primaevial or Pampalaeozoic era. They are exposed over about one-third of the continent. They outcrop from Cape Town to southern Egypt, and from the Gold Coast on the west to Somaliland, the eastern horn of Africa. Most progress in the classification of these rocks has been made in South Africa, where they have great mineral wealth. They are divided into three main divisions. The lowest, the Swaziland system, consists of gneisses and coarse schists; in addition to the typical areas in South Africa, it forms most of Africa, including Nubia, the highlands along the eastern and Atlantic coasts, and the Sudan from Abyssinia to Nigeria and the Gold Coast. This division corresponds to the old gneiss of other lands, such as the Laurentian of Canada and the Lewisian of Britain.

The second division consists of sedimentary rocks, including quartzites, limestones, dolomites and slaty schists, with vast sheets of volcanic rocks. They are classified in South Africa as the Witwatersrand, Ventersdorp and Transvaal systems. Some of the rocks are so little altered that they have been expected to yield fossils; but none has been found and the *Orthoceras*, said to prove the Ordovician age of the Otavi dolomite, was based on cylindrical concretions. Some of these beds were regarded as Lower Palaeozoic; but they are probably earlier owing to the absence of fossils, and their resemblance to the pre-Cambrian rocks of other continents. The representatives of this division include important cop-

per, lead and zinc mining fields in northern Rhodesia and the Congo basin, the goldfield of Kilo in the eastern Belgian Congo, the goldfields of the Gold Coast Colony and the less important gold occurrences that have been discovered in Tanganyika Territory and Kenya Colony.

The third division includes sandstones that are so little altered that they have been persistently regarded as the inland continuation of the Devonian red sandstones of the coast at Cape Town. The chief member is the Waterberg sandstone of the northern Transvaal, which is probably represented in Uganda by part of the Karagwe series (most of which is referable to the second division), and in Angola by the Oendolongo series. These sandstones are probably the equivalent of the Torridonian of Britain and the Keweenaw of the United States and Canada.

The Palaeozoic era began with apparently the whole of Africa as part of a continent, for the only Cambrian beds known in it are in Morocco near Tetuan, though the sea came close to the eastern coast in Sinai. No certain Ordovician rocks are known, though they have been doubtfully recorded from the Atlas mountains. Many beds in Africa have been called Ordovician and Silurian on inadequate evidence, but some Silurian beds with graptolites occur in the central Sahara.

The Devonian is the oldest African system with widespread fossiliferous beds. It includes the Bokkeveld beds in Cape Colony, and has a wide extent in the Sahara, Libya and the western Sudan, and it reaches the Atlantic on the Gold Coast; marine representatives occur of the lower, middle and upper divisions. Marine Carboniferous rocks occur to the north of the Devonian beds in Cape Colony and limestones with crinoids and *Productus* show that a contemporary sea covered part of Egypt. The Lower and Middle Carboniferous are widely developed in the northern and north-western Sahara, and in south-western Tripoli; and there are small outcrops by the Gulf of Suez. The Carboniferous land deposits are extensive. The lowest part of the Karroo system of southern Africa is Upper Carboniferous and includes the glacial Dwyka Conglomerate and rich coal seams. Coal is also found in southern Rhodesia, Tanganyika Territory and Lake Nyasa. The glacial deposits of this period extend northward into the Congo basin and southern Madagascar. The later divisions of the Karroo system range from the Permian to the Lower Lias and are represented in equatorial Africa; they have yielded many remarkable fossil reptiles. The Permian beds (Lower Beaufort) are represented by shales of freshwater origin with *Palaeonodonta* on the Sabaki in Kenya Colony, and the Trias (Upper Beaufort) by the Tanga beds and part of the Buruma sandstone, of which the fossil *Dadoxylon* forest may be the equivalent of that of the Molteno beds of South Africa. In the Congo there are large areas of sandstones, the Lualaba and Lubilache series, which, judging from their sparse fossils, are Permian and Trias.

There is no established marine Trias in Africa, except for a small development in southern Tunis and along the Atlas of beds like those in Andalusia; though the sea lay a little north in the Mediterranean, most of the Triassic beds of Algeria and Tunis are of the continental type, like those of England and Germany. The breaking up of Gondwanaland had nevertheless probably begun in the Trias, and in the next period, the Jurassic, marine beds were deposited along parts of the east African coast. An arm of the sea then ran up the Mozambique channel between Madagascar and the mainland. The eastern part of Madagascar consists of the primaevial gneisses and schists, on which rest some Karroo beds; the western slope consists of marine Jurassic, Cretaceous and Kainozoic beds, with some volcanic rocks. The Jurassic beds of Madagascar and Tanganyika Territory range from the Lias to the end of the system; further north, in Kenya Colony and Somaliland, the horizons established represent from the Bathonian to the Tithonian. In Tanganyika Territory the Upper Jurassic beds (Corallian to Tithonian) in Tenduguru are famous for their fossil reptiles, of which *Gigantosaurus* is the largest known animal.

The advance of the sea during the Jurassic received in East Africa a check in the Cretaceous; for though a Neocomian gulf ran northward from Uitenhage in Cape Colony past Madagascar, the lowest Cretaceous series is barely represented in Kenya and

its occurrence in Abyssinia is probably due to a gulf from the Mediterranean. The widespread Cretaceous rock of eastern Africa is the Nubian sandstone (possibly partly Upper Jurassic), a land deposit which extends from Egypt to Abyssinia and Somaliland. In Egypt an arm of the Mediterranean sea deposited Cretaceous beds, which represent all the series from the Lower Cenomanian to the Danian.

A Cretaceous strait in the Upper Albian and Senonian extended from the Mediterranean across the Sahara, past Lake Chad and along the Benue valley as far south as Angola. The Cretaceous in Africa is best represented in Tunis, Algeria and Morocco. At the beginning of the period the sea covered a narrow strip of land from the coast to just south of Tunis and Oran; but by the Middle and Upper Cretaceous compact limestones were deposited over much of northern Algeria, and the Cenomanian lagoons lay along the front of the Sahara.

In the same region the Cretaceous sea was succeeded directly by that of the Lower Eocene, wherein were deposited the phosphatic limestones that are the most valuable mineral deposit of northern Africa. A still wider submergence in the Middle Eocene formed the Nummulitic limestone, which ranges across northern Africa from Cairo through Cyrenaica and along the Atlas Mountains to Morocco; and a gulf southward extended on to some of the lower parts of the Sahara. A strait from this gulf continued to the Niger valley and covered the district of Sokoto, and reached the Gulf of Guinea in southern Nigeria and the Cameroons. The Oligocene saw a general retreat of the sea from northern Africa, but beds with small Nummulites were deposited in bays. The freshwater lakes of the Oligocene have yielded at Fayum the fossils which revealed to C. W. Andrews the story of the origin of the elephants from the primitive *Moeritherium*.

The Miocene sea along the Atlas was restricted to a strait from Oran to central Tunis, which was one of the passages that connected the Atlantic and the western Mediterranean. A renewed uplift at the end of the Miocene of the channel reduced these straits, though that south of the Riff in Morocco was apparently still occupied by the sea. In other parts of Africa the marine Cainozoic deposits are scanty. The sea occasionally reached the tropical coasts. A full series of Eocene limestones occur in Somaliland, with also the Upper Oligocene. Eocene and Miocene deposits occur both on the coasts of Kenya Colony and in Tanganyika Territory at Lindi; Miocene limestone occurs in the island of Pemba. The marine Pliocene of the Mediterranean is represented in Algeria and Egypt, while marine Pliocene deposits allied to those of the Persian Gulf also occur, notably in Zanzibar island and at Mombasa.

Africa, therefore, has a long stable development, which was occasionally interrupted by volcanic outbreaks connected with the fractures made by the foundering of the adjacent ocean basins. The eastern half of Africa appears to have been slowly upraised during the Mesozoic into a broad, flat arch contemporary with the formation of a great sea-filled trough along the East African coast. The wider subsidence that formed the Indian Ocean led to the giving way of the eastern side of the arch, and the infall of its roof formed the Great Rift valley, which extends from Mozambique throughout eastern Africa and along the Red Sea to the Jordan valley. The fractures connected with its formation were accompanied by great volcanic eruptions, and the Kapitan phonolites of Kenya Colony are probably contemporary with the Decan traps of north-western India. The earth movements connected with the formation of the Great Rift valley lasted from the Oligocene to the Pleistocene, and they were accompanied by repeated volcanic eruptions. They built up the two highest of African mountains—Kilima Njaro, which still has a crater upon its summit, and Kenya, which is the denuded neck of an old volcano. Subsidences around volcanic centres formed great cauldrons, such as Ngorongoro in Tanganyika and Menengai in Kenya Colony. Volcanoes along the fractures connected with the formation of the Atlantic produced the shonkinite vent at Chieuca in Angola, the volcano of the Cameroons, which is still active, while eruptions along a fracture parallel to the coast formed the islands of the Guinea Gulf, Fernando Po, San Thomé, Principé and

Annobon. The deepest subsidences along the Rift valley in Africa formed the lake basins of Tanganyika, Nyassa, the Albert Nyanza and Lake Rudolf.

The economic geology of Africa is connected mainly with its rich mineral fields, especially of gold and diamonds in South Africa, southern Rhodesia and the Gold Coast; of gold at Kilo; of diamonds, copper, zinc and lead in Northern Rhodesia and Katanga. Tin and platinum are found in the Transvaal, and chromium in southern Rhodesia. The most important phosphate deposits are along the Atlas Mountains. The only productive African oil-field is on the coast of the Gulf of Suez; oil-shale is known in South Africa, Nigeria and elsewhere; rich coal-fields are worked in the Transvaal, Natal and Southern Rhodesia; and coal also occurs in Tanganyika Territory, Nyassaland and Nigeria. Iron ores are widespread, as are also deposits of bauxite and manganese, which are most extensively worked on the Gold Coast. The chief African mica mines are in Tanganyika Territory.

TABLE OF FORMATIONS

CAINOZOIC

<i>Pleistocene.</i>	Raised coral reefs. Alluvial river and lake plains. Moraines on Kilima Njaro, Kenya, and Ruwenzori. Elephant beds in Zululand. Lavas and tufts of recent volcanoes. Gravels, desert sands, etc., with Neolithic and Palaeolithic implements.
<i>Pliocene.</i>	Marine beds in Tunis and Algeria. Sands with <i>Clypeaster</i> in Egypt. Limestones of Zanzibar, Pemba and Mombasa. Naivashan lavas in Kenya. Bone beds at Homa, Omo Valley, etc. Lavas in Atlantic islands, Aden, etc.
<i>Miocene.</i>	Marine limestones in Algeria and Tunis. Limestones of Pemba and Tanganyika coast. <i>Dinotherium</i> beds of Victoria Nyanza. Limestones of Egypt with oil-field of Gulf of Suez.
<i>Oligocene.</i>	In former bays along Mediterranean coastlands. Dubar limestone of Somaliland. Limestones N. of Mombasa and at Lindi. Lake beds of Fayum. Early faulting of Great Rift valley.
<i>Eocene.</i>	Nummulitic limestone of N. Africa coastlands; in Sokoto, northern Nigeria; Somaliland; Coasts of Kenya Colony. Tanganyika Territory. Sheringoma in S. Mozambique. <i>Ahuria</i> beds of S.W. Africa. Widespread volcanic eruptions in Kenya.

MESOZOIC

<i>Cretaceous.</i>	Neocomian to Up. Cretaceous along eastern coast of S. Africa. Neocomian-Cenomanian in Mozambique; Urgovian-Senonian in Tanganyika Territory. Cenomanian-Danian Egypt. Lower to Up. Cretaceous along the Atlas mts. Albian in Angola. Turonian, Benue valley. Kapitan Phonolites of Kenya Colony. Nubian sandstone in Nubia, Abyssinia, and Somaliland.
<i>Jurassic.</i>	Upper.—Meragalleh limestone in Somaliland and Kimmeridgian-Purbeckian, with giant reptiles and marine beds, in Tanganyika Territory. Ammonite beds near Mombasa. Middle.—Kenya and Tanganyika Territory. Lower.—Bathonian and Bajocian limestones in Tanganyika Territory, Kenya (Kambe limestone), Somaliland, and Madagascar. Lias. Tanganyika Territory and Jubaland. Rhaetic. Drakenberg lavas, Upper Tanga beds with plants. Coal series in Natal.
<i>Trias.</i>	Marine. Terrestrial Trias in S.S. Tunisia and Atlas Cave sandstone and Molteno beds. Mazeras sandstone with <i>Dadoxylon</i> forest in Kenya coastlands. Upper Beaufort. Kenya coastlands. Burghersdorp beds of S. Africa. Lubilache sandstones of Congo basin.

PALAEOZOIC

<i>Permian.</i>	Lower Beaufort in S. Africa. Tanga beds. Sabaki shales with <i>Palaeonodonta</i> . Tanga beds. Upper Lualaba sandstones of Congo.
<i>Carboniferous.</i>	Upper Uralian. Ecca beds with coal-fields of Transvaal and glacial Dwyka conglomerate in S. Africa. Wankie coal in S. Rhodesia. Coals in Tanganyika Territory and Congo. Glacial beds in Congo and Madagascar. Middle.—Absent. Lower.—Witteberg series of Cape Colony. Crinoid and <i>Productus</i> limestone in Egypt.
<i>Devonian.</i>	Bokkeveld series of Cape Colony. Marine beds of Sahara, Libya, and Sudan. Table Mountain sandstone.

Silurian.	Central Sahara.
Ordovician.	Absent.
Cambrian.	N.W. Morocco and Gulf of Akaba.

PAMPALAEZOIC (PRIMAEVAL)

- Upper Division.** Waterberg sandstone of S. Africa. Oendolongo beds, Angola.
- Middle Division.** Transvaal, Ventersdorp, and Witwatersrand systems in Transvaal and S.W. Africa with representatives in Rhodesia, southern Congo. Lepi series of Angola. Kandelurgu and Karagwe quartzites of Tanganyika and Uganda. Banket series of Gold Coast.
- Lower Division.** Swaziland system with gneiss Schists of the main foundation of the African continental plateau.

Authoritative works dealing with the continent of Africa as a whole in any of its aspects are comparatively rare. Besides such volumes the following list includes, therefore, books containing valuable information concerning large or typical sections of the continent.

1. General Descriptions: Herodotus (edit. G. Rawlinson, 4 vols., 1880); Ptolemy, *Geographia* (edit. C. Müller, vol. i., Paris, 1883-1901); Ibn Haukal, "Description de l'Afrique" (trans. McG. de Slane), *Nouv. Journal asiatique* (1842); Edrisi, "Géographie" (trans. Jaubert), *Réc. de voyages . . . Soc. de Géogr.*, vol. v. (1836); Abulfeda, *Géographie* (trans. Reinaud and Guyard, 1848-83); M. A. P. d'Avezac, *Description de l'Afrique ancienne* (1845); L. de Marmol, *Description general de Africa* (Granada, 1573); L. Sanuto, *Geografia dell' Africa* (Venice, 1588); F. Pigafetta, *A Report of the Kingdom of Congo*, etc. (1597); Leo Africanus, *The History and Description of Africa* (trans. J. Pory; edit. R. Brown, 3 vols., 1896); O. Dapper, *Naukeurige beschrijvinge der afrikaensche gewesten*, etc. (Amsterdam, 1668; also Eng. vers. by Ogilvy, 1670, and Fr. vers. Amsterdam, 1686); B. Tellez, "Travels of the Jesuits in Ethiopia," *A New Collection of Voyages*, vol. vii. (1710); G. A. Cavazzi da Montecuccolo, *Istoria della Descrittione de tre Regni Congo, Matamba, et Angola* (Milan, 1690; an account of the labours of the Capuchin missionaries and their observations on the country and people); J. Barbot, "Description of the Coasts of North and South Guinea and of Ethiopia Inferior," *Churchill's Voyages*, vol. v. (1707); W. Bosman, *A New . . . Description of the Coasts of Guinea*, etc. (2nd ed., 1721); J. B. Labat, *Nouvelle relation de l'Afrique occidentale* (5 vols., 1728), and *Relation historique de l'Éthiopie occidentale* (5 vols., 1732); B. d'Anville, *Mémoire conc. les rivières de l'intérieur de l'Afrique* (Paris, n.d.); M. Vollkommer, *Die Quellen B. d'Anville's für seine kritische Karte von Afrika* (Munich, 1904); C. Ritter, *Die Erdkunde* (i. Theil, 1. Buch, "Afrika," Berlin, 1822); J. M'Queen, *Geographical and Commercial View of Northern and Central Africa* (Edinburgh, 1821), and *Geographical Survey of Africa* (1840); W. D. Cooley, *Inner Africa laid open* (1852); E. Reclus, *Nouvelle géographie universelle*, vols. x.-xiii. (1885-88); A. H. Keane, "Africa" in *Stanford's Compendium* (2 vols., 2nd ed., 1904-07); M. Fallex and A. Mairey, *L'Afrique au début du XX^e siècle* (1906); Sir C. P. Lucas *Historical Geography of the British Colonies*, vols. iii. and iv. (1894, 1904); *Journal of the African Society*; Comité de l'Afrique française: *Bulle-*

tin; Mitteilungen der afrikan. Gesellschaft in Deutschland (1879-89); *Geographical Journal*.

11. Geology, Climate, Flora, Fauna:—E. Krenkel, *Geologie Afrikas* (1925); L. de Launay, *Les Richesses minérales de l'Afrique* (1903); A. Knox, *The Climate of the Continent of Africa* (1911); P. Reichard, "Zur Frage der Austrocknung Afrikas," *Geogr. Zeitschrift* (1895); *Peterm. Mitt.* (1905); G. Fraunberger, "Studien über die jährlichen Niederschlagsmengen des afrik. Kontinents," *Peterm. Mitt.* (1906); D. Oliver and Sir W. T. Thiselton-Dyer, *Flora of Tropical Africa* (10 vols., 1888-1906); K. Oschatz, *Anordnung der Vegetation in Afrika* (Erlangen, 1900); A. Engler, *Hochgebirgs-flora des tropischen Afrika* (1892); *Die Pflanzenwelt Ostafrikas und der Nachbargebiete* (3 vols., 1895), and *Beiträge zur Flora von Afrika* (Engler, Botan. Jahrbücher, 14 vols., etc.); W. P. Hiern, *Catalogue of the African Plants collected by Dr. Friedrich Welwitsch in 1853-1861* (2 vols., 1896-1901); W. L. Sclater and P. L. Sclater, *The Geography of Mammals* (1899); H. A. Bryden and others, *Great and Small Game of Africa* (1899); F. C. Selous, *African Nature Notes and Reminiscences* (1908); E. N. Buxton, *Two African Trips: with Notes and Suggestions on Big-Game Preservation in Africa* (1902); G. Schillings, *In Wildest Africa* (1907); R. Lydekker, *The Geographical History of Mammals* (1896); A. R. Wallace, *The Geographical Distribution of Animals* (1876). (X.)

ANTHROPOLOGY AND ETHNOLOGY

North Africa and Egypt.—Apart from Egypt and the Nile Valley the divisions of Africa north of the Sudan are in the main political and from the anthropological standpoint almost entirely artificial. Not only are the Egypto-Tripolitan and the Morocco-Algerian frontiers entirely conventional, but even the Libyo-Tunisian frontier lacks the ethnic significance it might possess if instead of leaving the Mediterranean in the neighbourhood of Cape Roux it ran almost due south from the Gulf of Gabes. The political divisions of the western portion of North Africa—Africa Minor—thus stand in sharp contrast to its natural unity, so well defined between the desert and the Mediterranean that the early Arab geographers named it Geziret el Magreb, "the Western Island." It is also necessary to realize that the predominantly Arab complexion of North Africa and the general substitution of Hamitic languages by Arabic began little more than 1000 years ago, while to appreciate the vast area of country over which the spread of Arab influence has obliterated or modified the earlier Berber tongues reference should be made to some such linguistic map as that given by Meinhof in *Die moderne Sprachforschung in Afrika* (Berlin 1910).

The Berbers and Their Position in North Africa.—While Sergi (*Antropologia della Stirpe Camitica*, Turin, 1897) regards the Berbers as the northern branch of the Hamitic stock (the Eastern Hamites being typically represented by proto-Egyptians, Beja and Galla), Keane (*Man, Past and Present*, Cambridge, 1920) quotes T. A. Joyce to the effect that it is impossible to prove the connection between Eastern and Northern Hamites, and that the latter should be regarded as the African representatives of the Mediterranean race. The question is largely a matter of terminology, since we cannot doubt the close relationship of the groups commonly termed Mediterranean, proto-Egyptian, and Beja.

The term Moor, which is often applied to the townsmen of Morocco, is here purposely avoided, and with Collignon and Deniker ("Les Maures du Senegal," *L'Anthropologie*, 1896) is restricted ethnically to a group of peoples lying between the Senegal River and Morocco and extending east to the Tuareg country.

Egypt.—For Egypt alone in North Africa it is possible to construct a connected anthropological record, which, in spite of gaps, reaches back to the very dawn of history. Some thirty years ago Flinders Petrie and J. E. Quibell discovered at Naqada and Ballas in Upper Egypt a series of cemeteries belonging to a people with a mode of life and habit of burial utterly different from those of the dynastic civilization previously known in Egypt. Their discovery was followed up and extended by de Morgan, who recognized that Petrie's "new race" preceded even Mena, traditionally the first ruler of a united Egypt, whose tomb he found and excavated. Unfortunately de Morgan applied the term "neolithic" to this newly discovered people, a complete misnomer—though still used in French works—since detailed archaeological examination indicates that copper occurs in the earliest graves in

these cemeteries. These early inhabitants of the Nile Valley are now known as the predynastic or proto-Egyptians, terms which respectively emphasize their position in time and their ethnic relation to the other inhabitants of the Nile Valley.

The Pre-dynastic Egyptians.—The proto-Egyptians have been best described by Elliot Smith, who writes of them (*The People of Egypt*, Address to Cairo Scientific Society, 1909) as a people slightly below the average size of mankind, with muscular development so feeble that it may be difficult to determine to which sex an isolated skull belongs. In physical character they exhibit a remarkable degree of homogeneity. Their hair was dark, and either straight or wavy, never woolly. In the men apart from a chin-tuft beard there was the scantiest development of facial hair. These proto-Egyptians had long narrow heads with a narrow forehead and prominent occiput, so that the skull when viewed from above presents a characteristic form which has been termed "coffin-shaped." The face was a moderately long and narrow ellipse, and the chin was almost always pointed. More precisely, they were longheaded, with a cranial index of 73 (Naqada) and a mean height estimated at a little under 65 inches for men and about 60 inches for women, and though there can be no direct evidence as to skin and eye colour there is no doubt that they had dark eyes and skins of a yellowish brown or pale copper colour.

The Dynastic Egyptians.—All this applies only to the population of Upper Egypt; knowledge is lacking of the inhabitants of the delta at this early period, as of the whole of Lower Egypt until the time of the pyramid builders. Among the skeletons of this date from the neighbourhood of the pyramids Elliot Smith found a considerable number in which the skeleton was more robust, with a bigger and especially a broader skull without the angularity and the projecting occiput of the proto-Egyptian type; there are modifications in forehead, orbits and nose, with particularly obvious differences in the jaw, in fact the type of man round the pyramids belonged to that well characterized group known as the dynastic Egyptian, which in antiquity is represented by the Saqqara "Scribes" and the Sheikh el Belled, and is essentially that of the peasant Egyptians, the *fellahin* of the present day. For a detailed account of skeletal material, and especially of crania, throughout the dynastic period see A. Thomson and D. Randall-Maciver *The Ancient Races of the Thebaid* (Oxford 1905). Elliot Smith (*The Ancient Egyptians*, 1923, chapter 7), arrays evidence that long before the New Empire, Egypt was permeated from end to end by this foreign element, which in his opinion carries the physical traits of the Armenoid race. There is however one difficulty in accepting this view, which does not arise from any examination of the skeletal remains but results from the large number of portrait statues which the Egyptians have left to us, namely, that although so many of these statues exhibit the broader face and heavier jaw brought in by the alien race, not one of them exhibits any approach to the typical Armenoid, so-called "Jewish," nose. If therefore the foreign element is to be termed Armenoid it can only be called by this name so long as it is realized that this does not imply the presence of one of the most characteristic features of that race as known at the present day. The difficulty is not lightened by the fact that less than 1000 years later at Beni Hassan there are excellent representations of the Aamu, a people of the eastern desert with typical Armenoid noses.

Contemporary Representations of Beja.—The proto-Egyptian type persists to the present day among the southern Beja (*q.v.*), tribes of the Anglo-Egyptian Sudan. It also occurs, though probably in less typical form, among the Ababda of the Eastern (Egyptian) Desert and the riverain settlements in the neighbourhood of the first cataract. We have direct evidence dating from about 2000 B.C. of the existence of the pure proto-Egyptian type among a people wearing their hair in the same fuzzy mop as the Beja of the present day on the eastern border of Egypt. Among the wall paintings of the 12th Dynasty in the tombs at Meir (A. M. Blackman, *The Rock Tombs of Meir*, vol. ii., Pl. xxx., London, 1915), is one that undoubtedly represents a Beja. The long thin figure and limbs, with broad chest, narrow

flanks and retracted abdomen, are no doubt conventional and exaggerated representations of the characters of the lean pastoral desert men as they appeared to the agricultural Egyptians, but there can be no criticism of the splendid naturalism of the lined face, the thin pointed nose and the mop of hair projecting over the forehead and standing out stiffly over the whole head to the nape of the neck. The beard is the usual chin tuft of the Beja tribes, and comparison with modern Beni Amer clinches the identity of the two peoples, living in the same desert area but separated by 4,000 years. Confirmatory evidence of the proto-Egyptian characters of the inhabitants of the eastern desert and of their civilization is offered by the discovery by G. W. Murray of a burial of late pre-dynastic date, with characteristic grave goods, near Ras Samadi on the Red Sea Coast, in lat. 24° 59' N. (*Man* 1923, 81). The skull accorded well with those of the pre-dynastic Egyptians.

The desert must indeed be regarded as a reservoir not only of early archaic physical types no longer preserved in the richer Nile lands but also of ancient ideas and appliances, *e.g.*, the camel stick of the Ma'aza of the Eastern Desert is no other than the *Uas* sceptre of ancient Egypt applied to a new use.

The Arab Element.—The Arab conquest, which politically altered the whole history of Egypt, had no appreciable influence on the physique of its inhabitants. While in part this may be due to a certain physical resemblance between Arabian and Egyptian the numerical inferiority of the conquerors must be held to be the determining cause. The nature of the invasion may be best illustrated by considering the history of the Juhaina (Sudanese, Guhayna, *q.v.*). The tribesmen took a prominent part in breaking the power of the Christian kingdom of Nubia; yet in spite of their importance in the past, at the present day few groups that may fairly be called Arabs exist except in association with the desert. Such are the fisher folk of Lake Menzaleh, who trace their origin to Sinai; the Harabi of the Fayum, extending into the Tripolitan desert, still pastoral nomads; the Aulad Ali of the Behera district of the Delta, no longer nomads; and the practically sedentary Howeitat of Matarieh; all dolichocephals or low brachycephals. In the Eastern Desert the only important Arab tribe is the Ma'aza, about whom very little is known, described by Chantre (*Recherches Anthropologiques en Egypte*, Lyon, 1904), as short dolichocephals.

Besides these more or less well-defined groups there is in upper Egypt a small number of people, generally mobile in their habits, living along the edge of the cultivation. These folk generally keep goats and often own a few palm trees, and formerly may have been of more importance as charcoal burners. Somewhat in the position of gypsies in England fifty years ago, they are generally unpopular with the *fellahin*, on whom they levy a certain amount of blackmail. Such groups as the Bili, near Baliana, and the Aleiqat, of whom there are a considerable number near Qus, do not come into this category.

In Sinai, with a total population of some 10,000, the chief tribes are the Howeitat, the Tiyaha and Terabin, in the North; in the South the Tawara (*i.e.*, the people of Tor), who include the Aleiqat, the Sawalha and Muzeina.

The Modern Egyptian.—Passing to the *fellahin*, the modern Egyptian, the most important of the numerous studies that have been made are those of C. S. Myers ("Contributions to Egyptian Anthropology," in vols. xxxv., xxxvi., and xxxviii. of the *Journal of the Royal Anthropological Institute*) and of J. R. Craig ("Anthropometry of Modern Egyptians," *Biometrika*, vol. viii., 1911). Omitting the province of Aswan and the town dwellers, these papers, which must be regarded as complementary, indicate that the Egyptian peasant has a stature of approximately 65½ in., showing no sharp division between Upper and Lower Egypt; he is longheaded, with a cephalic index of about 75, the cephalic index—again omitting Aswan—being about a unit higher in Lower than in Upper Egypt. There is no evidence that the natives of various provinces differ in variability, nor is it possible to resolve distribution curves, whether of measurements or indices, into components corresponding to hypothetical underlying ethnic types, though it seems that passing from Lower to Upper Egypt

eye and skin colour darken and the proportion of unusually broad noses increases as does the frequency of spiral and crisp hair, all evidences of increased though still well diluted negro blood in the population.

The position of the Copts (the Christian population of the present day, and therefore with insignificant exceptions the descendants of the Egyptians who refused to relinquish their faith at the Conquest or during the succeeding centuries) is particularly interesting. The observations available refer to Coptic peasants, not town dwellers, and so far as these go the remark commonly made by Europeans that they can distinguish at sight between Muslim and Copt is not borne out. No significant deviation from the general Muslim population is found as regards head measurements or facial characteristics, though the nose is slightly less broad and the lip slightly thinner, with eye and skin colour a trifle lighter. Thus, diagnosis at sight between Copt and Muslim, if really practicable, cannot rest on easily defined physical characteristics but must be attributed to such other factors as gait, dress, etc.

The measurements and photographs of natives of Kharga Oasis published by Hrdlicka (*The Natives of Kharga Oasis, Egypt*, Washington, 1912) show that its inhabitants are Egyptians, differing in no essentials from the inhabitants of the Nile Valley. The inhabitants of Siwa speak a Berber dialect, akin to Tuareg, with many Arabic loan words, some so profoundly modified that their origin is not immediately apparent. Jaghub (Jarabub), in Italian territory, is believed to have been uninhabited before its occupation by the Senussi, whose capital it now is.

Disposition of the Fellahin.—Difficult as it is to sum up the temperament or disposition of a people it is probably true to say that the *fellahin* are in the main good natured, cheerful and excitable, genuinely religious but not generally fanatical, though certain centres such as Tanta have a bad reputation in this respect. They are liable to occasional bursts of ferocity (such as distinguished the rioting of 1919), and inter-village enmities, leading to fights with iron-shod staves, were formerly fierce and persistent. Nothing approaching an adequate account of the beliefs and customs of the *fellahin* has yet been written, for Lane's *Modern Egyptians*, first published in 1836 before western influence had contaminated Egyptian habits and modes of thought, though giving an invaluable account of Cairene life and manners cannot be held to apply except in somewhat general terms to the habits and beliefs of the peasants, which even preliminary inquiry will show to vary not only from those of the towns but as between Upper and Lower Egypt. Meanwhile the work of Miss Winifred Blackman (*The Fellahin of Upper Egypt*, 1927) avowedly only a preliminary account, contains much useful information.

Tattoo, etc.—Tattooing is the most obvious, common and widespread method of bodily enhancement and mutilation. Lane mentions the simpler designs—dots, lines and circles—common in women and refers to the “extremely displeasing” habit of the women of Upper Egypt of discolouring their lips with tattoo. C. S. Myers (“Contributions to Egyptian Anthropology, Tattooing,” *J.R.A.I.*, vol. xxxiii., 1903) found that of about 400 male subjects nearly 100 were tattooed, the designs falling into two main classes, namely simple, generally geometrical, designs, and pictorial representations, e.g., the façade of a mosque or the Persian lion with sword. Local examples of the type prevailing throughout North Africa form the first class while the latter are derived from eastern sources. Circumcision is universal; clitoridectomy, though far less recognized by Europeans, is customary

in cities, at least among the poorer class, and may be equally common among the Fellahin. Both long antedate Islam, circumcision being represented in a tomb of the pyramid age at Saqqara, while clitoridectomy or a similar operation is alluded to by Strabo—*Circumcidunt etiam mares et foeminas excidunt*.

Survivals from Ancient Egypt.—One of the most interesting features of present day Egypt is the persistence in popular belief of ideas traceable to ancient Egypt, especially intricate ceremonies connected with mourning, the survival of the belief in *ka* or double, the persistence of a ceremony in which a sacred boat takes a prominent part, and the superstitions connected with particular days in the calendar. The boat ceremonies are particularly important, since these exist widely in Asia outside the Near East (e.g., in Ceylon) and it seems probable that their distribution has been to a considerable extent brought about from Egypt by the spread of Islam. Nearly 20 years ago the writer observed a full-sized river boat suspended in a tree outside Luxor; enquiries showed that once a year this was placed in a cart, filled with children and dragged round the fields. Actually there are three boat processions every year in Luxor, the most important being observed in honour of Abu'l Heggag, the patron saint of Luxor. The substitution of Amon and his sacred barque by Abu'l Heggag and his Nile boat is suggested by the popular belief at Karnak that on certain nights the golden boat of Amon may still be seen to emerge from the waters of the sacred lake, steered, as of old, by the Pharaoh.

The calendar customs are a striking example of how beliefs attached to a particular day may last for over 3,000 years, persisting through a complete change in the mode of reckoning time, as well as the introduction of new beliefs. The Sallier papyrus, which dates from the time of Rameses II. or possibly his successor, gives an account of the lucky and unlucky days in the year, and describes in some detail the quality of the good and bad luck, with instructions for behaviour on each of these days. It may first be noted that the five epagomenal days of the old Egyptian year were unlucky. In modern Egypt the epagomenal days are still observed to the extent that neither sowing nor planting should be undertaken, mares and cattle should not be covered lest their offspring be misshapen, and it is even believed that children begotten during these days will show some abnormality. A still more interesting example perhaps is that afforded by a day near the end of the old Egyptian month of Choiak; the Sallier Papyrus marks the 26th of this month as most unlucky, and of this day it is written, “Do not eat fish. Those residing in the midst of Tattu turn themselves into the fish An.” The mythological allusion cannot be explained, but the modern popular calendar, such as is hawked about the Bazaars, notes that on the 11th of Moharram (corresponding to the 26th day of the Coptic month Kyhak) “the eating of pigeons is liked, that of fish disliked.”

The Beja Tribes of Egypt.—Of the Beja tribes of the eastern desert the Ababda (*q.v.*) fall wholly within Egyptian territory; the Bisharin extend some 80 miles south of the boundary and occupy a strip of territory stretching along the right bank of the Atbara. While the physical characters of both tribes have been studied by E. Chantre (*Recherches Anthropologiques en Egypte*, Lyons, 1904) and the mode of life of the Bisharin described by Linant de Bellefonds (L'Etchaye, 1858), two recent papers by G. W. Murray (“The Ababda,” *J.R.A.I.*, vol. liii., 1923, and “The Northern Beja,” vol. lvii., 1927) constitute by far the most valuable account of these people. The Ababda inhabit the eastern desert from the Sudan frontier to north of the Kena-Kuseir road, and there are isolated colonies along the edge of the cultivation from Assiut to Korosko. In the time of Bruce their southern range was limited by the 'Atawna (Arabs) who have now vanished from the desert. Earlier yet Makrisi records the Beli (Bili) a tribe of which scattered groups still exist along the edge of the cultivation—as being in possession of parts of the desert now belonging to the Ababda. The desert Ababda intermarry with the Bisharin, and those settled in the Nile Valley with the Fellahin, but they do not appear to intermarry with any Arab tribes still carrying the desert tradition. Like other Beja tribes the Ababda wear the *dirwa*, the shock head-dress of hair

BY COURTESY OF NORTHERN BAPTIST CONVENTION

A NATIVE OF BELGIAN CONGO

Of powerful physique and expert huntsman, a few of the tribes in the Belgian Congo persist in cannibalism

besmeared with mutton fat, though this custom is gradually dying out. Unlike their Beja neighbours to the south the Ababda speak Arabic, but coloured by Bedauey (*To-Bedawi*) words, while transposition of consonants—a Hamitic rather than a Semitic feature—often occurs.

In physique the Ababda resemble the Beni Amer, and therefore the predynastic Egyptians, *i.e.*, they are longheaded with a cephalic index of 73.6 and a stature of 1.63 metres. The Bisharin on the other hand present two types, those of the Red Sea coast with a cephalic index of 74.7, and those living inland with a cephalic index of 78.4, the latter substantially identical with the index given by Chantre, presumably derived from individuals living in or near the Nile Valley. (Murray, *op.cit.*)

Tripoli.—Westwards beyond the Egyptian frontier knowledge of the physical anthropology of Tripoli is but slight. At the extreme west of Italian territory, *i.e.*, in the area surrounding Tripoli city, the systematic observations of Bertholon and Chantre show that the population is predominantly long-headed and of rather low stature (below 1.65 m.) but there is an island of high brachycephaly in the immediate area of Bu Ajilat, though these brachycephals exhibit no marked departure from the general low stature of the area. Throughout the rest of Tripoli but few observations have been made, certainly not enough to permit of any connected anthropological history or description of the country. The observations of the late Oric Bates at Mersa Matruh, not far east of the Egyptian frontier (*"Archaic Burials at Marsa Matrûh"* *Ancient Egypt*, 1915, Part IV., p. 158) suggest that at a period possibly as remote as that of the pyramid builders the population of the coastal plain was not unlike that of the proto-Egyptians, and presumably a people of some such type long continued to form the basis of the population of the coastal plain. Evidence such as that afforded by the ram of Bu Hamama (in Algiers) crowned with the sun-disk and uraei, as well as the presence of the sun-disk on Carthaginian coins, indicates the very considerable cultural influence exercised by Egypt along the north African littoral in late dynastic times, but so far there is no direct evidence of Egyptian influence on the physical anthropology of the country. Nor is there any knowledge in this sense of the effect of the Roman occupation. Herodotus, however, describes the Libyans east of Lake Tritonis, *i.e.*, the inhabitants of Tripoli, as nomadic and thus differing from the settled agricultural peoples of what is now predominantly Algeria, although it is clear that many of these people were in fact no more than semi-nomadic; the Nasamones for instance with their main settlements on the Syrtic shore, left their herds in summer and went up to Aujila for the date harvest, just as some "nomad" Arab tribes of the present day sow their crop in the oases in the autumn, leading a more or less wandering life until the spring.

Apart from the littoral belt the greater portion of Tripoli is desert or poor steppe, for the most part with an annual rainfall varying from three to less than ten inches, such a country can never have been densely populated or have offered any great temptation to highly civilized folk. The position is different with regard to nomads or semi-nomads; here is a sparsely inhabited area which could scarcely fail to attract the Arab tribes that poured into north Africa after the conquest of Egypt under the Khalif Omar, and again in the eleventh century when, in 1048, the Wazir of the Fatimid Khalif Mustansir launched a number of the nomad tribes of Upper Egypt, including the Beni Halal, against his master's orthodox vassals of the northern African States. Each man was given a camel and a gold piece on condition that he would settle in Maghreb, with the result that within two years Cyrenaica had been pillaged and Kairwan captured. But the western movement of the Hilali invasion did not stop here, for while the majority of the Beni Hilal settled in Tripoli and Tunis, and the Athbej passed into what is now Algeria, as far as the Aures mountains and the river Zab, the Makil pressed westwards as far as the high plateau of Morocco-Algeria. Beneath this flood the Berber tongue largely disappeared, and except among the Beni M'zab, the Abadite schism was almost wiped out.

At the present day the population of the coastal plain may for practical purposes be regarded as Arab, and since with the excep-

tion of the towns and the oases of the far south the coastal plain—never more than 20 miles in width and generally less than this—constitutes almost the whole of the available territory suitable for agriculture, the Arab tribes of this area form the predominant factor in the population of the country. Of these tribes the Awlad Ali may be taken as the type. Extending from the outskirts of Alexandria to the neighbourhood of Tobruk they grow a considerable amount of barley, and (at any rate before the Great War) possessed horses, sheep and camels, the latter constituting their main wealth. Predominantly sedentary, and horsemen rather than camel-men, they yet live in tents. Their tribal organization is into sections and divisions as among the Arabs of the Sudan, whom (*e.g.*, the Kababish) they closely resemble physically to judge from the measurements given by Chantre. But not all the folk who have been described as Tripolitan Arabs are long-headed; an examination by Mochi (*"Presentazione di crani d'indigeni di Tripoli"* *Archiv. per l'Antrop. e la Etnol.*, Florence XL, 1912, p. 381) of the skulls from Tripoli in the National Museum at Florence indicates that they contain at least one hyperbrachycephalic group. Remarkable as is this fact, its significance becomes clear in the light of a series of skulls described by Giuffrida Ruggeri (*"I Crani Egiziani antichi e Arabo-Egiziani dall' Università di Napoli," Atti dell' Società Romana di Antropologia*, XV., 1910, pp. 112 *et seq.*) from an ancient Arab cemetery at Abassieh near Cairo, with an average cranial index (13) of 85.3. The significance of these skulls and their relation to definite areas of round-headedness in Tripoli has been studied by Seligman (*"The Physical Character of the Arabs," J.R.A.I.*, vol. xlvii., 1907), who points out that their characters indicate that the Abassieh skulls belonged to natives of Southern Arabia, that brachycephaly prevails both in southern Arabia and in the Levant, and that both these areas have contributed to the population of North Africa.

Barbary (Tunis, Algeria, Morocco).—Tunis, Algeria and Morocco, are but artificial political divisions of one natural area, which from the anthropological as well as the geographical aspect might still be called by its old name of Barbary. Its inhabitants, the Berbers, are commonly regarded as aborigines, and apart from immigrant stocks this seems to be true as far back as the end of the palaeolithic period. The physical anthropology of the natives of Eastern Tripoli, Tunisia and Algeria, has been exhaustively studied by Bertholon and Chantre (*Recherches anthropologiques dans la Berberie Orientale Tripolitaine, Tunisie, Algerie*. Lyon, 1912). The following facts give a rough idea of the progressive weakening of Arab influence, passing from East to West, and the physical characteristics of the three main groups generally recognized.

In Tunis, with a total Islamic population of something under two millions, there are about half a million Berberized Arabs and less than 100,000 Berbers, forming for the most part two isolated masses, the Matmata in the far south in the neighbourhood of Jebel Nefusa, and a group mainly of the Abadite (Kharijite) heresy in the island of Jerba. Passing westwards to Algeria there are pure Berber groups in the Kabyle hills and in the Aures mountains. Apart from these two areas the remainder of the province of Constantine may be regarded as inhabited by Arabized Berbers except for a few Arab coastal areas. Numerically some 75% of the inhabitants of the province may be regarded as Berber or Berber-speaking, the remainder Arabs or partially Berberized Arabs. In the department of Algiers Arabs mixed with Arabized Berbers preponderate, while in Oran the Arab element is frankly dominant. In Morocco on the contrary the Berbers are not only in great numerical majority but socially form by far the most important groups. Here it is calculated that not more than five per cent of the population are Arabs, with perhaps another five of Berberized Arabs, the remainder of the population being fairly equally divided into pure Berbers and Berbers with a tinge of Arab influence. Nothing would be gained by attempting to enumerate the "Berber" and "Arab" tribes of Morocco. Westermarck (*The Moorish Conception of Holiness*, Helsingfors, 1916) divides the Berbers into five groups:—(1) the Ruâfa—the Berbers of the Rif—whose country extends along the

Mediterranean coast from the neighbourhood of Tetuan to the Algerian frontier; (2) the Beräber, who inhabit the mountain regions of Central Morocco and the eastern portion of the Great Atlas; (3) the Shleuh, inhabiting the western part of this range, and to the south of it in the province of Sûs a territory with an eastern frontier running from Demnat in a south-easterly direction and a northern frontier uniting Demnat with Mogador on the Atlantic coast, following more or less closely the foot of the mountains; (4) the Draa, who inhabit the valley of the Wad Draa in the extreme south of Morocco; (5) various tribes living in the neighbourhood of Ujda, in the north-east of the country. The so-called "Arabs" are the Jebala, the mountain-dwelling tribes of Northern Morocco, with their centre in the area between the Rif and Fez and extending westwards of the latter.

Physical Characteristics of the Berbers.—Morocco, is from the standpoint of physical anthropology for the most part unexplored. Three physical types of Berber are, however, generally recognized: (1) tall men, with a stature of about 1.70m., dolichocephalic, with strongly marked supraorbital ridges, the face long, tending to oval, the cheek bones by no means prominent, nose long and narrow, chin square and rather scant beard. This type appears to form perhaps half the population of Tunisia and is widespread in Algeria. (2) The second type is short, with a stature of about 1.63m., longheaded, with a prominent occiput so that the head when viewed from above is distinctly pentagonal; the face is short and broad, the cheek bones well developed, the nose tends to be broad, the chin prominent and often well bearded, the lips full. This type is to be found in the mountains of central Tunisia, in the neighbourhood of Gabes and of Algiers, in the south of Algeria, as well as all over Morocco. It seems to be generally accepted that the skulls found in the megalithic monuments of this part of Africa belong to one or other of these types. (3) The third group is of moderate stature, 1.64m. to 1.65m., and brachycephalic. The face is broad and short, the forehead round (*bombé*), nose short and broad. This type is specially present in the Island of Jerba and in the oasis of M'zab; it is also found in the hills to the south of the Gulf of Gabes, western Tripoli, and on the Algerian littoral, as well as among the Kabyles and the inhabitants of the Aures hill. Many of the M'zab have a skin so pale that they burn wheaten colour rather than brown in the sun.

While the number of the blonde Berbers certainly varies locally and their proportion has no doubt often been exaggerated (at least in Algeria), a competent anthropologist, the late Anthony Wilkin, specially studying the problem, has recorded that of the observed population of El Arbaa fully 20% were "fair men" (*Among the Berbers of Algeria*, 1900, p. 77). Good observers always lay stress on the essentially white quality of the skin of the pure Berber tribes. The origin of this blonde element has been much discussed; it is no doubt foreign—presumably Nordic, with perhaps Alpine admixture—and it existed in Libya as long ago as the New Empire, as is shown by contemporary paintings in Egyptian tombs.

Cultural Characteristics of the Berbers.—On the psychical side some of the main Berber characteristics can perhaps be best appreciated by contrasting them with those of the Arab; moreover such a comparison is particularly useful since apart from the Nile Valley it in some sense embodies an epitome of the history for some 1,200 years of the whole of North Africa.

The Berber is essentially an agriculturist, with a passionate love of the soil upon which he has been born, though a keen trader, often willing to take service abroad but always anxious to return to his village in his old age or when he has amassed a competence. He is a stern fighter, often a determined brigand and in religious matters a born sceptic, while his strong democratic tendencies are indicated by his social organization in which leadership is usually a matter of election, though raiding and war may give real authority to individual strong men which may to a limited extent pass to their descendants. In contrast, the Arab is typically a nomad pastoralist, whose attitude to agriculture is mirrored in the proverb that shame enters with the plough, a poor worker, whose real courage is less likely to be shown when raiding than on a point

of honour or as an expression of his religious faith. Moreover, Arab society is essentially aristocratic; the Arab is, and always has been, ruled by hereditary leaders, and his struggles when he does revolt are spasmodic, and directed against the individual rather than the system. With this aristocratic and religious bias there exists a strong contempt not only for the stranger but for Muslims of other sects, and here again he stands in strong contrast to the Berber. These contrasts are of course not absolute; there are nomad Berbers, and many sedentary Arabs; some Berbers become really good Mohammedans, though generally there is much truth in the epigram that the Berber is not a Mohammedan but only thinks he is. Moreover, in the West, *i.e.*, in Algiers and Morocco, there is always the difficulty of knowing whether a given people not obviously Berber or Arab should be regarded as Arabized Berbers or Berberized Arabs. Here social organization and history rather than language seem to be the best guides.

Political and Social Organization of the Berbers.—In spite of the religious and cultural influence of Islam the social organization of the Berbers differs in every essential from that of the Arabs. The following outline (*see* MacIver and Wilkins, *Libyan Notes*, London, 1901), in principle valid throughout Barbary, applies specifically to the Kabyle Hills. The Berbers are typically hillmen, living in isolated villages, formerly often well fortified or with a central citadel, and, while possessing flocks and herds which in particular instances may regulate their mode of life, are essentially skilled agriculturists, who have long practised irrigation and are quick to take advantage of every scrap of cultivable ground in the difficult and often sterile hills among which they live.

The unit of government is the village, each possessing complete autonomy. A number of villages form the tribe, the connection being administrative and not regulated by kinship. A union of several such tribes may be termed a Confederation; the bond is looser than in the lower federative grade and the confederation never interferes in the affairs of its tribes unless directly appealed to or when vitally necessary. In time of war a head is appointed for each of the tribes and for the confederation. The tribe has deliberative and administrative duties, such as the determination of questions of peace and war, the making of roads, and manages tribal property such as mosques, tombs of saints, and educational establishments; it is concerned with the levying of taxes necessary for these purposes, and may act as arbiter between villages. A general assembly of the tribe is almost unknown, its affairs being managed by a deputation of the chief men from each of the villages composing it.

Every village is brought into contact with its neighbours by means of its *sof*, of which there are always two, the term signifying a group whose members covenant to render mutual aid to one another in cases of necessity. In each village the two *sof* are in some sense opposed, and each *sof* will be allied with similar fraternities in neighbouring villages, the ramifications of the *sof* organization extending through entire districts. Within the village the members of each *sof* are united by the closest bonds, the obligations ranking above all personal interests and even ties of kinship. Nevertheless, though loyal to his *sof* while he is a member of it, the Kabyle thinks little of transferring his allegiance from one *sof* to another if he thinks he will gain thereby, and outside the village the members of a *sof* though willing to assist their fellows with provisions and even with money would expect to be paid for any active armed assistance they might give. The funds of the *sof* are raised by subscription from members and are administered by the heads of the organization, usually men of powerful families and of private wealth, who may disburse considerable sums on secret services without rendering account to the members.

Within the village affairs are controlled by the *jemâa*, the general assembly of the citizens, of which every adult man is a member though in practice only the old men and heads of families exercise the right to speak. Nothing which concerns the welfare of the village escapes the control of the *jemâa*—it exercises judicial authority, makes laws, levies taxes and administers the public property. Decisions are not taken by a majority of votes

NATIVES OF WEST AFRICA

1. An inhabitant of Diola, in Senegal, with ornaments and jewellery
2. Natives of Mankena, in Senegal
3. Ful woman from French West Africa, with headdress and earrings
4. A Moorish camp on the desert
5. Native fishing canoes on a river in West Africa
6. Tuareg warriors from the neighbourhood of Timbuktú
7. Native method of canoe-manufacture in West Africa. Pieces of wood are sewn together

but unanimity is required, and if the assembly fails to arrive at an agreement the discussion may be adjourned, or reference made to an arbiter chosen from among its members or from another village. The executive head of the Assembly is the Amin, sometimes called *amekkeran* (chief) or *amrân* (old man), usually a member of one of the leading families, a man of wealth and able to rely absolutely on the support of his *sof*. He is put forward by the influential persons of the village, the appointment being ratified by the Assembly. His duties include public finance, but except in small matters he has no independence or initiative and cannot act without the consent of the *jemâa*, over whose meetings he presides. He has assistants who are in some sense "police," supervising the various quarters of the village and giving information of all that passes.

Although emphasis must be laid on the agriculture and even the horticulture of the Berbers—the Shawia of the Aures Mountains and the Kabyles being regarded as typical—the Berbers are also pastoralists, and in the higher mountains the seasonal change of pasture-land (*cf.* French *transhumance*), plays an important part in their social life. Thus in the Middle Atlas, a tract of plateaux and peaks some 7,000 feet high merging in the west into the Tadla plain and in the south into the High Atlas, there is a heavy winter snowfall as low as 3,000 feet, which determines a transhumance of the winter type (as in Europe in the Carpathians and Balkans), the flocks being driven down to the lowlands. The familiar summer type of transhumance of the Mediterranean valleys also occurs in the Middle Atlas, the animals leaving the dried sun-parched valleys for mountains; indeed in the Middle Atlas some tribes—as the Beni Mgild—practise both forms, and such tribes when the winter movement leads them far into foreign territory do in fact approach a nomadic life. The so-called nomadism of the Berbers in Morocco should not, therefore, be classed with the wanderings of such true nomads as, *e.g.*, the Berber-speaking Tuareg.

Arts and Crafts.—The Berbers are good craftsmen. The best Kabyle silver work is probably as good as any made by Africans, many of their tribes make excellent carpets, and in studying their decorative art it is possible to make the generalization that apart from Arab influence their limiting lines are straight, not circular or even arcs of circles. This is particularly obvious in their architecture, even when advanced, as in the minarets of their finest mosques, *e.g.*, in Marrakesh, Rabat (and even in Seville) the mosque towers are square in section, or sometimes hexagonal, contrasting notably with the rounded minarets of Egypt and the Near East generally. So too the designs woven into their carpets by the more typically Berber peoples of Morocco is geometrical, often rectangular, and always made up of straight lines. Nevertheless, Arabic influence has brought in the arc and the cupola, the latter as common in the *Qubba* (saints' tombs) of the countryside as in Egypt.

The hand made pottery of the Berbers of Algeria, and especially of the Kabyles has excited much interest; it was even suggested that it betokened a direct and somewhat close relationship between the ancient inhabitants of Algeria and the proto-Egyptians (MacIver and Wilkins, *op. cit.*, give good coloured plates of Kabyle pottery; see also papers by MacIver and by J. L. Myres in *J.R.A.I.*, vol. xxxii, 1902). It is now generally held that the red-faced pot fabrics of Kabylia descend directly from the widespread red-ware of the Neolithic period, so that their resemblance to certain types of pottery of pre-dynastic Egypt is secondary. As regards the characteristic geometric designs, usually black on white or yellow, of the area, these too descend from the endemic geometrical art of north Africa, though affected by Mediterranean influences, especially Aegean. Further, since the Punic settlers of the early Iron Age used the wheel, the survival of hand-made fabrics in the mountains is of interest as defining the rather limited quality of outside influences to which the mountaineers have been subjected.

Medicine and Surgery.—By far the greater part of medicine proper is little more than magic, but there is evidence that, in spite of the recognized danger of the necessarily large doses, henbane (*Hyoscyamus albus*) may be used before operations

for its sedative and alleged paralytic and anaesthetic qualities, while in surgery trepanning is successfully performed for fractured skulls. The *dura mater* is never incised—indeed every attempt is made to avoid touching it—and the danger of the brain bulging through the wound (*hernia cerebri*) is appreciated and special means taken to prevent it. As might be expected, dead bone is freely removed when necessary, but the repair of limbs does not stop here; bone grafting is practised, grafts taken from a dog being most approved, and the cases recorded seem to indicate that the operation may be successful. Other operations include the removal of pterygium from the eye, and, it is said, occasionally lithotomy.

Berber Folklore.—The folk beliefs and customs of the Berbers are particularly well known as the subject of the classical works of Doutté (*Magie & Religion dans l'Afrique du Nord*, Alger, 1908) and, especially, Westermarck (*Marriage Ceremonies in Morocco*, 1914, *Ritual & Belief in Morocco*, 2 vols., 1926). Among outstanding examples of the successful study of the magic and superstitions (in the sense of unorthodox beliefs) of a barbaric people, may be mentioned the ceremonial use during the *ashura* ceremony (*i.e.*, the festival held on the tenth day of Moharram, the first month of the Muslim year) of two figures, male and female, called by the names *Yaghussa* and *Yauka*, who according to local popular belief were idols of olden days. These can be none other than the pre-Islamic gods *Yaghûth* and *Ya'ûq* mentioned in the Koran (*sura lxxi*, v. 23). The extreme rarity of the persistence of the names of pre-Islamic deities makes this of particular interest, and suggests the early date at which Arab influence began to be felt.

Sudan.—The Anglo-Egyptian Sudan, including Darfur, incorporated in 1916, has an area of over a million square miles, measuring roughly 1,300 miles from north to south (lat. 22° N.

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

MAT WEAVING, A COMMON INDUSTRY AMONG THE TRIBES OF SOUTHERN AND CENTRAL AFRICA

to lat. 4° N.) and at its greatest breadth over 1,000 miles from east to west (long. 21° 30' E. and long. 30° E.). It is divided into fifteen Provinces and one Military District, the latter the Sobat-Pibor between the Nile and the Abyssinian frontier. Although a number of these Provinces are well characterized units from the historical or geographical standpoint, they are not generally delimited on lines of ethnic significance, and no attempt to hold to them will be made in the following account.

The population of the Anglo-Egyptian Sudan may most conveniently be considered under two headings, Northern or Mohammedan, and Southern or Pagan. The former embraces the peoples of the dry regions of the north, Islamic in religion and culture, predominantly Arab in language, and at least in part Arab in origin. The Pagans include the great mass of the negro or negroid tribes of the south, though nowhere are the two zones clearly defined by any single degree of latitude.

Even the northern area has no ethnic unity: in the east the Red Sea and Kassala provinces are in the main Hamitic, and many of the riverain Arabs of the White and Blue Niles carry at least as much negro as Arab blood, both superimposed upon older Hamitic stocks which were predominant in the land before the

introduction of Islam. In the south, although the negro has given his name to the Sudan (*Bilad el-Sudan*, the Land of the Blacks of mediaeval Arab authors) and has excited the greatest interest from mediaeval times onwards, yet adequate knowledge is lacking of the habits, customs and religion of any one tribe.

The tribes of the Northern area belong to two great families, (a) Hamite, and (b) Arab. The Hamites proper include the group of tribes known historically as the Beja (*q.v.*) inhabiting the Red Sea Province and outside the Anglo-Egyptian Sudan extending into Eritrea. Less purely Hamitic, but none the less to be classed as Hamites, are the inhabitants of Nubia, commonly called Berberines or Barabra (*q.v.*), for, in spite of much negro blood and a language which is commonly regarded as negro, history indicates that fundamentally they are of Hamitic origin, while their civilization is not and seems never to have been negro in character. (See ARABS, BARABRA, BEJA.)

The true negro undoubtedly represents one of the most primitive of the African stocks. His main physical characteristics are tall stature, a "black" skin, woolly hair and moderate dolichocephaly, a flat broad nose and thick and often everted lips, prominent cheekbones and a varying degree of prognathism. With these qualities there go certain cultural characteristics. Such true negroes are found in the far western Sudan and the Guinea Coast, but hardly in the valleys of the Nile or of its affluents where as far as many of its most characteristic groups are concerned there is evidence of old Hamitic mixture. It is indeed scarcely possible to go further than this at the present time. In a classification proposed by Westermann, based on linguistic criteria, the term Nilotic is used in a sense so wide that it seems to signify no more than related to the Nile valley, but within it three groups are constituted, "High," "Middle" and "Low" Nilotic, which in part at least may be natural.

1. The High Nilotic group, comprising Mittu, Madi, Abukaya, Abaka, Luba, Wira, Lendu and Moru.

2. The Middle Nilotic group, comprising Shilluk, Anuak, Beir, Jur, Belanda and many of the peoples of Eastern Uganda, the Acholi, Lango (*q.v.*), Aturu and Jaluo.

3. The Low Nilotic group, comprising Dinka and Nuer.

This classification, though of wider geographical scope, embraces the whole of the Anglo-Egyptian Sudan, but the Bari with their numerous constituent "sub-tribes" are not mentioned, nor are the Lotuko-speaking tribes. Westermann places the former in his Nilotic-Hamitic group, *i.e.* with the Masai, Turkana, etc. to which the Lotuko-speaking tribes may also be assigned. For descriptive purposes, the following scheme is proposed:

A. Tall "black" dolichocephals, comprising Dinka, Shilluk, Nuer, Anuak, with perhaps some others as yet unclassified. These are the typical Nilotes of most writers, and in this article the term will be confined to this group. The mesaticephalic Acholi no doubt arose within this group, which probably also gave origin to the Belanda and the (Shilluk-speaking) Jur.

B. Tall "black" mesaticephals (probably sometimes brachycephals) comprising some Nuba and probably a number of the little-known tribes of Dar-Fung, including the Barun.

C. Medium statured "black" dolichocephals, comprising the Bari (but probably not the majority of the Bari-speaking tribes of the west bank), the Lotuko-speaking tribes and perhaps some of Westermann's High Nilotic group.

D. Short mesaticephals, with skin showing a coppery tinge—the Azande—or with blacker skins as the Bongo, Mittu and probably a number of the tribes now constituting the Azande nation. Knowledge of this group is very limited.

This classification by no means includes all the tribes of the Sudan. Many of the peoples of the Bahr-el-Ghazal Province are quite unknown ethnologically, *e.g.* the Moro, the Kaliko, the Bukuru (Babuckur) and the Liggi, and even the relations of such important Bari-speaking tribes of the west bank as the Mandari, Kuku, Kakuak, Nyangbwara and Fajelu, are far from clear. Nor is there any substantial knowledge of the Madi, who in the south cross the political boundary into Uganda. In the east, on the borders of Uganda and Abyssinia, are groups of unknown tribes, some of which may constitute ethnic units, *e.g.* Didinga, Longarim,

Murle, with perhaps further north and nearer the Nile the Beir (Ajiba), all said by J. H. Driberg (unpublished information) to speak dialects of one language. The position of the Dongotono is obscure, while Driberg considers the Lorwama to be a section of Lotuko-speaking Lango. (C. G. S.)

EAST AFRICA

The geographical area which is included under this designation extends roughly from the north frontier of Kenya Colony as far south as the Zambezi, and includes Kenya Colony, the Uganda Protectorate, Tanganyika Territory, Nyasaland and Portuguese East Africa.

We cannot say for certain who were the original inhabitants of this vast territory, for as yet our archaeological data are too scanty, but a number of tribes preserve in their mythology and legends recollections of what may have been a bygone autochthonous race. Thus the Akikuyu tell of cannibal dwarfs known as Maitoachiana, and both the Nandi and Masai have traditions of fantastically shaped ogres with cannibalistic instincts. Probably the nomads, who still exist under a variety of names wherever the natural conditions permit, represent the earliest inhabitants of whom we can have any knowledge. In this area they occupy a subordinate, almost a servile position, live by trapping and hunting, or by collecting roots and berries, are often shy, elusive creatures of the forest, rarely seen, and at other times are engaged in what their neighbours consider the menial task of blacksmiths, and always dreaded for their knowledge of poisons and witchcraft. Excluding these nomads, the races of East Africa fall into the following groups: (1) Bantu; (2) Nilotic; (3) Nilo-Hamitic. The Bantu are subdivided into Lacustrians and eastern Bantu. The classification is really linguistic, but happens to be sufficiently valid in this case as a cultural criterion. Thus by Bantu are meant all those peoples of Africa who use the root *ntu* or some similar word to express human being. *Ba-* is the plural personal prefix of which *mu-* or *omu-* is the singular. Thus we speak of *Muganda*, a Ganda person and *Baganda*, Ganda people. As the prefix is really redundant we shall refer to the Bantu tribes without the prefix and speak of Ganda, Nyoro, Swahili and so on.

The history of East Africa is the history of the Hamites, for the various groups are differentiated by the degree and nature of their Hamitization. The Bantu-speaking peoples are an early mixture of negroes and Hamites, and a series of later waves from the north-east, culminating in the great upheaval of the 16th century, of which the Galla expansion under Mohammed Granye and his invasion of Abyssinia in 1537 was a symptom, profoundly affected East African cultural relations. The Lacustrians were further Hamitized and a Hamitic autocracy imposed itself on many of the conquered Bantu peoples to the north and west of Lake Victoria. The Nilotics or inhabitants of the Nile valley, a parallel fusion of negroes and Hamites, with possibly a Semitic element added as well, were dispossessed of their tribal territories in what is now the south-eastern Sudan and were dispersed by invaders from the east. The bulk of them moved northwards and became the modern Shilluk, Dinka and allied tribes, but a few followed natural lines southwards, and to-day are known as the Acholi, Lango, Alur, Jopalu and Jaluo. The invaders themselves were what are often known as "Half-Hamites," a rather meaningless term to which Nilo-Hamitic is preferable, as they are in fact increasingly Hamitized Nilotics. Southern Abyssinia and regions round Lake Rudolf have during the last 400 years witnessed a perpetual ebb and flow of immigrant peoples, more and more Hamitized, who were deflected by the Nile valley and moved southwards to populate the highlands of Kenya Colony and Tanganyika, until gradually the whole area from these highlands to the Horn of Africa was filled up with mainly pastoral peoples of Hamitic ancestry. This centrifugal movement southwards was

only checked by the intervention of western Powers in whose absence the process would undoubtedly have continued despite temporary checks such as the defeat of the Masai at the hands of the Bantu Hehe. This wedge of Nilo-Hamitics thrust southwards into Bantu areas appropriated the highlands to their pastoral requirements and separated the eastern Bantu from the Lacustrians. The eastern Bantu were agriculturalists and content with the lower highlands and the coastal regions, but under the stress of isolation came very much under the influence of their Hamitic neighbours, and though linguistically they remain Bantu they have assimilated many of the characteristic features of Hamitic culture.

The coastal belt and the adjacent islands, including Zanzibar and Pemba, are inhabited by the Swahili, whose language is morphologically Bantu and who are therefore generally classed as such. Culturally, however, they are not homogeneous and have few Bantu affinities. Since Abdul Malik bin Muriani brought his Syrian builders in A.D. 659 to found his African kingdom, a succession of colonizing waves from Persia and from the Oman established a Mohammedan empire over the whole coastal region from the Lamu archipelago to the Zambezi. These immigrants brought their own culture, interbred with and assimilated the local Bantu at each of their administrative and trading centres. Thus was gradually formed the Swahili language, largely Arabic in origin, though structurally Bantu; and this was the genesis of what are now known as the Swahili people, or more properly the Swahili-speaking peoples, a heterogeneous conglomerate of localized dialects and customs, based on the original Bantu tribes who both assimilated the alien Mohammedan culture and incorporated in it no inconsiderable portion of their own. There were early Chinese voyages to the east coast of Africa, relics of which in pottery and coins, have survived on the coast from Lamu southwards. The Mongoloid eye found sporadically throughout this area, may also be a survival of Chinese infiltration, though other explanations are possible.

The Lacustrian and eastern Bantu meet in Tanganyika Territory and gradually the typical Bantu characteristics reassert themselves, though now we find a social organization with a more pronounced military bias than we encounter farther north. Typical of such tribal polities are the Hehe of Tanganyika Territory and the Yao of Nyasaland, whose organization, though much the same as that of their neighbours the Anyanja, is more closely knit and adapted to the exigencies of war. This may in part be due to the influence of the Angoni, an offshoot of the Zulu who fought their way north and penetrated as far as the southern shores of Lake Victoria. They were finally conquered by the Nyamwezi, a tribe also Zuluized and organized for military purposes, and were permitted to settle in their present homes. The Simba appeared on the lower Zambezi in 1540 and triumphing over the Portuguese and their African allies pushed north-east and succeeded in capturing Mombasa, before they were finally defeated and apparently annihilated near Malindi. The whole of this southern area has for centuries been the battle-ground of warring tribes, marching and counter-marching in almost inextricable confusion, achieving an evanescent eminence and as rapidly fading to comparative insignificance. Consequently there are fewer individual characteristics, the distinctions are less clearly cut, and their affinities are southern and western rather than northern. They belong to the southern Bantu more than to the Lacustrians despite the common characteristics which are part of the Bantu inheritance as a whole. The Thonga of Portuguese East Africa, for instance, very definitely merge into the southern complex and in Nyasaland the Anyanja extend into Rhodesia and come into contact with distinct Zambezi affinities.

In an area so complex and so full of cultural conflict it would be difficult to summarize the salient characteristics both briefly and adequately. Overlapping between the different groups is inevitable owing to the diffusion of cultural elements from one to the other and emphasizes the impossibility of a rigid classification. A fair picture, however, may be obtained of tribal cultures (social organization, mode of life and religious beliefs) by a concise examination of representative tribes in each group, with allowance for individual variation from the norm. The nomads require

separate mention, and the Ganda and Ankole represent the Lacustrians. The Nyika group represent the eastern Bantu. The Hehe and Angoni represent the fusion of the Lacustrians and the eastern Bantu with their southern influences. Lango represent the Nilotics and Masai the Nilo-Hamitics.

WEST AFRICA

West Africa was inhabited in prehistoric times, ancient stone implements being found in Senegal, the Sudan, French Guinea, the Ivory Coast, Gold Coast and Nigeria, and sites are frequently found in the Sahara in regions now barren, but which no doubt anciently enjoyed different climatic conditions. North Africa was probably peopled by men of Mediterranean race, then by Eastern Hamitic people (dark-skinned, fine features, soft hair), the modern Berber resulting from their admixture. Later came the Jews and Arabs. The Pygmies or Negrilloes, were pushed back by negroes from Central Africa, and were established in the area lying between the Sahara and the Gulf of Guinea and between the Atlantic and Lake Chad. Negrilloes and negroes at first interbred among themselves, then mixed with Berbers and peoples of Hamitic and Semitic stock, thus giving rise to higher grade peoples such as the Bornuan, Kanuri, Hausa, Mandingo, Yoruba and Ashanti.

Principal Ethnic Groups.—The following provisory classification rests on physical, cultural and institutional data:

- I. White race: Berbers, Fulani
- II. Black race:
 - a) Senegalese-Guinea family
 - b) Nigerian Senegalese "
 - c) Volta "
 - d) Guinea "
 - e) Lower Nigerian "
 - f) Hausa "

Social Organization: General.—The social unit is the family in the strict sense, and more often the extended family, a group occupying the same enclosure whose members are divided into classes consisting of parallel generations having equal rights, with labour and ownership in common. Several related family groups form a village quarter. The distinct and organized clan is rare; more easily distinguished is the identity of the tribe and sub-tribe. Matriarchy is rare. Marriage is seldom exogamous, nearly always patrilocal; the children are attributed to the father, and descent is usually traced in the paternal line. Family authority devolves upon the father or the patriarch assisted by elders. Common ownership of family goods, with individual ownership of personal property, is almost universal. Women are usually at liberty to dispose of their own property. Succession to the family possessions, of which women form part, is vested sometimes in the brother and sometimes in the son of the deceased. On the Ivory Coast, in the Upper Volta and Nigeria, a husband allows his wife to cohabit with another man, the children belonging to him. Marriage between brothers-in-law and sisters-in-law is frequent. Personal possessions are heritable in the same way as family goods, but frequently men succeed to a man's goods and women to a woman's.

Government.—Many bush peoples (Liberia, Ivory Coast, Southern Nigeria) and peoples of the French Sudanese region (Gourounsi, Bobo, Lobi, Bariba) live in small independent groups. Elsewhere kingdoms have been constituted, very often theocratic in character and ruled over by a priest-king or by a king and a priest reigning together (Nigeria, Dahomey, French Sudan, Upper Volta) and uniting the civil and magico-religious power. Ministers and councillors assist the sovereign. The Queen-Mother (Gold Coast, Nigeria) possesses authority. The heir to the throne is often chosen, by an electoral group, from certain families according to local hereditary laws.

Religion.—Islam spread, in particular, over Mauritania, Senegal, the Guineas, the Niger valley, the Hausa country, Bornu and Nigeria; elsewhere, there is general belief in a supreme deity, in a sky and an earth god, and in inferior gods. Respect is paid to ancestors. Gods and ancestors share in the life of the social group. Various methods of divination are in vogue to ascertain their will. Infraction of certain sacred inhibitions (murder, the shedding of blood) are displeasing to the gods and are regarded as sins and require compensation and expiation. Family and clan cults are found, more rarely tribal cults. Sacrifices, frequently of a seasonal character (altars, trees, stones, hills, streams), insure fertility and fecundity, there being a close association between magic and religion. The head of the family is the domestic priest, and the descendant of the first occupant of the country is the priest of the earth. Sacerdotal colleges, male and female, are frequent (Dahomey, Ashanti, Yoruba). Traces of totemism are found in French Sudan, Ashanti, Dahomey, Nigeria. Numerous tribal, clan, family, individual, occasional and professional tabus, probably of totemic origin, are recorded.

Belief in witchcraft is general, the sorcerers being supposed to be able to change themselves into animals, injuries to the animal inflicted during the metamorphosis appearing on the sorcerer's body. There are special laws and punishments for sorcery.

Initiation of members of the social group is by successive degrees in secret ceremonies to adolescents, adults and men of full experience. They seclude the grades in the forest or in sacred groves. The neophyte is considered to have died and to have been reborn with a new personality, and receives instruction (moral, religious, technical, aesthetic). His position in the group depends on initiation. There are similar but less complicated ceremonies for women.

In Nigeria the king was frequently slain after he had reigned for a certain period, or when he grew old (Yoruba, Jukun, Hausa); the same custom appears to have existed in the French Sudan (Mandingo, Dogon).

Cannibalism and head-hunting have almost disappeared, but existed on the Ivory Coast, in Liberia, Dahomey and Nigeria. In former times human sacrifices were followed almost everywhere by a feast at which the victim was eaten. (H. LAB.)

SOUTH AFRICA

The natives of Africa south of the Kunene, Okavango and Zambezi rivers fall into three main divisions, known respectively as Bushmen, Hottentots and Bantu. These divisions represent a series of successive waves of southerly migration by which the peopling of the country has been effected. The Bushmen, a race of short yellowish-brown nomad hunters, are the earliest human inhabitants of South Africa of whom there is any reliable historical record. Recent archaeological research, however, has established clearly that they were not the first to occupy the country, but are an invading people who superseded the original inhabitants of this part of South Africa. From the evidence afforded by their cultural remains it seems likely that at a very early time they occupied the hunting grounds of tropical East Africa and gradually passed southwards until, when the written history of the country begins, they were roaming all over the territory south of the Zambezi river.

By this time they were already being encroached upon by the Hottentots, who resemble them greatly in racial characters and in language, but are a pastoral people with a more complex material culture and social organization. The Hottentots seem to have sprung out of a mixture of the old Bushman population of East Africa with an early migration of Hamites from whom they obtained their cattle and certain elements of their language. They migrated south later than the Bushmen, and after crossing the upper waters of the Zambezi passed on to the west coast and down to the south coast, where they were found by the first Europeans to touch at the Cape.

The Bantu peoples are the latest of the native inhabitants to have entered South Africa. They all speak languages belonging to the characteristic Bantu language family of Africa (*see* AFRICAN LANGUAGES), but in racial characters they vary considerably,

though certain negro characteristics predominate. They seem to have originated as a distinct variety somewhere in the neighbourhood of the Great Lakes and to have migrated South at various times between about the 12th and 15th centuries, each of their main groups (*see* below, *Principal Groups*) representing a different series of tribal movements.

The impacts upon one another of all these different peoples, and the later advance inland from the Cape of the European settlers, resulted in a complicated series of wars, migrations and exterminations, in which the Bushmen and the Hottentots were almost completely broken up, while the original distribution and condition of the Bantu were profoundly disturbed (*see* SOUTH AFRICA, *History*).

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

A HAUSA HEADMAN

More Arab than negro, the Hausa peoples are intelligent, well developed physically and good traders

ful, and are increasing in numbers. They are divided into numerous small tribes which on the basis of cultural and linguistic differences, may be classified into the following groups:—

(a) Eastern, or Zulu-Xosa, which occupies the coastal region East of the Drakenberg mountains and South of the Sabi river. This group includes the so-called "Kafirs" of the Transkei (*i.e.*, the AmaXosa, AmaMpondo, AmaMpondomisi, and AmaTembu), the "Fingoes" of the Cape Province, who are the fugitive remnants of tribes broken up in Natal during the great inter-tribal wars at the beginning of last century, the Zulu peoples of Natal and Zululand, with their offshoot the Matabele (AmaNdebele) of Southern Rhodesia, the AmaSwazi of Swaziland, and the BaThonga (AmaTonga) and kindred tribes of Portuguese East Africa.

(b) Central, or Sotho-Chwana. This group occupies the greater portion of the interior plain North of the Orange river, and includes among many others the BaTauana about the Botletle river and Lake Ngami, the BaMangwato of North Bechuanaland, the degraded BaKalahari of the Kalahari desert, the BaKwena, BaNgwaketse, BaRolong and BaTlaping of Central Bechuanaland, the BaHurutse, BaPedi, BaKgatlha and kindred tribes of West and Central Transvaal, the BaVenda of the North East Transvaal and the celebrated Basuto of Basutoland.

(c) The so-called "Mashona" peoples of South Rhodesia, including the BaNyai or BaRoswi and the AbeNanswa immediately South of the Zambezi river, the MaKaranga (MaKalanga), WaManyika and BaZezuru of Mashonaland and the VaNdau of Portuguese East Africa.

(d) South-western, comprising the OvaHerero and the OvaMbo peoples of South West Africa. They are each divided into various tribes which between them occupy the northern half of the region between the Western fringe of the Kalahari desert and the Atlantic ocean.

Another distinct, though less important, division of the natives of South Africa is constituted by the Bergdama (Haukhoin), who inhabit the coastal region of South West Africa. Their racial history is still far from clear. Physically they are a true negro people, yet they are isolated far from others of their kind; they

live an extremely primitive life, and speak the language of the Naman, to whom they have long been in subjection.

Social Organization.—Both the Bergdama and the Bushmen have very simple forms of social structure. Among the Bergdama the social units are small, independent local groups, each consisting of a patriarchal family, together with any relatives who may put themselves under the protection of its head, and sometimes including a certain number of dependent families who do not feel capable of founding a settlement of their own. The Bushmen are divided into small hunting bands, each of which owns a definite hunting territory over which it wanders and out of which it may not venture except with the permission of the neighbouring group. Within this territory members of the band are free to go where they like. The organization of the band is of the loosest kind. There is no chief, but skilled hunters and the older, more experienced, men in general have a great influence in directing social affairs. The only other structure of any importance is the family, consisting of a man and his wife, or wives, with their dependent children. Marriage within the band appears to be forbidden. A wife generally joins her husband's people, although in some of the northern tribes the young couple remain with the wife's parents until after the birth of the first child.

Of the Hottentots the only section whose social organization has been studied are the Nama, comprising several tribes, each of which has its own territory, name and chief. The tribe, however, is not a centralized body, but is made up of a rather loose aggregation of clans with the chieftainship hereditary in one of them. The authority of the chief is slight. The heads of the other clans act as his council, and he cannot do much without their co-operation. Each clan consists of a number of families claiming descent from some remote ancestor in the male line after whom they are named, and marriage within the clan is strictly forbidden. Polygamy was formerly practised, but monogamy is now the rule.

Among the Bantu peoples considerable variation exists in details of social organization, but certain general features prevail. Each tribe occupies its own territory under its own chief. His authority is generally considerable, but his actual power is somewhat modified by a council consisting of some of his relatives and the more influential heads of families. The family or household group is always of great social importance. It is normally polygamous, and generally forms a distinct local unit, except among the central tribes, where there is a tendency for different household groups to collect together in villages. Even here, however, each household is distinctly marked off from the rest. Within the household each wife has her own hut; and with her children constitutes an economic unit with well defined legal rights. Marriage is patrilocal, and is legalized by the payment of a bride-price (*lobola*), generally in the form of cattle. There exists also an organization of the people into clans, which, except in the eastern group, are associated with totemism. Clan exogamy is customary, but does not obtain among the Sotho-Chwana tribes. Membership of the clan is determined by descent through the father, except among the OvaMbo, who are matrilineal people, while the OvaHerero have a double system of clans, one set with patrilineal descent, the other with matrilineal (*see later, General Features of Note*).

Mode of Life.—Levels of culture differ considerably. All the Bushmen in their original condition are hunters and collectors. They practise neither agriculture nor pastoralism, but derive their subsistence entirely from the game they hunt and from the wild vegetable foods which the women collect. Their chief hunting weapons are the bow and small arrows with detachable poisoned points, but they also make use of throwing-sticks, pitfalls, traps and snares of all kinds, while the women have pointed digging-sticks, which are sometimes weighted with perforated stones. They are a nomadic people, confined in the dry season to places well supplied with water-holes, but, when the rainy season comes, wandering about freely within the limits of their hunting territory. Their encampments are temporary, and their dwellings crude shelters of rush or reed. The Bergdama on the whole lead a similar mode of life, although many of them also keep goats.

The Hottentots are chiefly a pastoral people, with herds of long-horned cattle and flocks of fat-tailed sheep. Sour milk forms

a staple element of their diet; and in contrast to all the Bantu except the OvaHerero, it is not the Hottentot men, but the women, who do the milking. Hunting also plays an important part in their economic life, their methods of hunting and their weapons being practically identical with those of the Bushmen. To some extent they are also nomadic, as fresh pastures for their herds are necessary from time to time. Their encampments, however, are less impermanent than those of the Bushmen. They live in beehive huts, covered with reed mats, and their settlements are arranged in circular form, leaving in the centre an open space in which the cattle are collected at night. Their material culture is on the whole superior to that of the Bushmen; in particular they smelt iron for the manufacture of their implements and weapons, while the Bushmen barter with the neighbouring Bantu peoples for whatever iron they require.

With the exception of the OvaHerero who are a purely pastoral people, all the Bantu tribes practise both hoe-culture and pastoralism. The eastern tribes are more predominantly pastoral, the others more agricultural, but all have this combined means of subsistence. Each household group has its own cattle and goats, as well as its own fields. The cattle are the concern of the men (except among the OvaHerero, where the women do the milking), the fields that of the women. The food supply is derived mainly from sour milk and from crops of millet and maize, supplemented in minor forms by pumpkins, peas, beans, etc., while for meat they rely chiefly upon the game hunted by the men. Cattle are never slaughtered for food except on ceremonial occasions. The life of the people is more or less sedentary. The eastern and south-western tribes live in beehive huts of thatch, the central and Mashona tribes in circular huts with conical roofs. The settlement is always arranged on the circular principle already noted among the Hottentots. All the industries are essentially domestic, practically everything required by the household being made within it. The one exception is in the case of iron implements and weapons, for which there are special workers, who barter their products for cattle and grain.

Religion, Special Features.—In religious beliefs there are certain fundamental features which appear to be common to both the Bushmen and the Hottentots, but there is also considerable variation in several important details. All Bushmen pray to the moon and other celestial bodies, and have an extensive series of myths and legends relating to them. They believe also in certain mythical beings, known variously to different tribes as Cagn (the mantis), Huwu, Tora, Gauna, etc., who appear to be personifications of natural forces, especially those producing the rain, and are frequently invoked. These mythical beings are credited with creative powers, and are met with in various myths of origin. From references in their myths and folk-tales it appears that the Bushmen have further a well developed system of ritual relating to animals and other sources of food, but it is not known in any detail what that ritual is or was. There seem also to be certain beliefs and practices connected with the spirits of the dead, but concerning these the information available is vague.

The religious cult of the Hottentots seems in general to consist mainly in the worship of mythical heroes derived partly from animistic beliefs and partly from the personification of the natural forces producing rain. In their general attributes these beings, chief of whom are Tsui-goab, Heitsi-Eibib and Gaunab, strongly resemble those of the Bushmen. The worship of the moon also seems to have been prevalent among the Hottentots at one time, judging from the records of prayers made to it for food and rain. There is further an extensive ritual relating to the cattle, which, as the chief source of food, are of paramount importance to the well-being of the community; while water, another extremely important factor in the economic life of the Hottentots, also plays a part in numerous ceremonial performances and taboos. One of the chief functions of the medicine-men, as among the Bushmen, is always the making of rain.

Among the Bantu, the religious cult is very largely a strongly developed form of ancestor worship. This is primarily a domestic cult, each family through its eldest male representative worshipping its ancestors in the male line. On important tribal occasions

the chief also prays to his ancestors on behalf of the tribe as a whole. The ancestors are regarded as guiding the destiny of their living descendants, and are propitiated by means of sacrifices offered on ceremonial festivals such as birth and marriage and on other special occasions. All the Bantu have also some conception, often rather vague, of a power in the universe which is not connected with the ancestors. This power is often associated with the sky, but shows itself most impressively in the phenomena of the weather, and hence rain, lightning and thunder are considered its manifestations. It is also sometimes looked upon as the creator of all things and the moulder of destiny. It is met with under various names (such as Tilo among the BaThonga, Unkulunkulu and Inkosi among the Zulu, Modimo in the central tribes and Nzame among the OvaMbo), and the beliefs and customs relating to it differ considerably from tribe to tribe. There is further an extensive ritual relating to agricultural life and to the cattle (the OvaHerero have a sacred herd of cattle), while traces of a totemic cult are found in all the tribes except the eastern. Magic and witchcraft play an extremely important part in the lives of the people, and in connection with this shamanism has developed to a high degree, so that there are many different kinds of medicine men with special functions, such as rain-making, divining, "doctoring" the crops, purifying the army, healing disease, etc.

General Features of Note.—In physical appearance there are many features which readily distinguish the Bushmen from all other inhabitants of South Africa, save the Hottentots. They are typically short in stature, but not dwarfish. Their limbs are slight and finely shaped, the hands and feet being especially small; but there is a curious curvature of the spine which gives a great prominence to the buttocks, where also a great accumulation of fat (steatopygia) sometimes occurs in the women. The skin is yellowish-brown in colour, and wrinkles very easily. The hair is woolly and sparse, commonly very short, and is scattered on the head in little tufts, or "peppercorn" fashion. The head is small and markedly low in the crown, the face broad, with prominent cheek bones, bulging forehead and convex upper lip, the nose extremely flat, the eyes narrow and often slightly oblique; frequently there is no lobe to the ear. In the more northern and eastern tribes there is a distinct tendency towards greater stature, darker colour and better muscular development, while the head and face are longer and higher. These divergent characters are the result of intermixture with the neighbouring Bantu peoples.

The culture of the Bushmen is noted for the highly artistic paintings and engravings which they executed on the walls of caves and rock-shelters. The subjects portrayed are chiefly animals, human beings, hunting, battle and dancing scenes, and the representations are remarkable for their fidelity to nature. The practice of the art seems to have died out, but it proves a most important link in the chain of evidence connecting the Bushmen of South Africa with the Palaeolithic cultures of the peoples of Europe.

Of the social customs of the Bushmen, especially those connected with birth and marriage, little is known. Initiation ceremonies at puberty are common to all Bushmen. On reaching her first menstrual period a girl is secluded in her hut and has to observe various food taboos. In the northern tribes a special religious dance, known as the "eland bull" dance, is added in her honour. Initiation ceremonies for boys seem to be restricted to the northern tribes. The special tribal marks are cut by the medicine men between the eyebrows of the boys, who are then kept in a secluded spot for about a month. During this time they are instructed in the lore of the tribe, and religious dances are held in which animal masquerades predominate. The Tati Bushmen practise circumcision as part of the initiation ceremony, but they are the only Bushmen of whom this is known, and have probably adopted the custom from the Bechuana among whom they live. At death the corpse is usually buried lying on one side with the knees drawn up against the breast. The group then removes to another site.

The Hottentots resemble the Bushmen closely in appearance, and it is only in certain characters that there are any noticeable differences. They are taller than the Bushmen, and have dis-

tinctly longer and narrower heads. Their skull is also higher and the face more prognathous. They have, however, the same prominent cheek bones, small chin, flat nose and peculiar eyes as the Bushmen, while their ears are often also lobeless. Their hair and their skin colour are the same as in the Bushmen, and steatopygia is often more marked.

An important feature in their culture is the great prominence of the communal meal in their ceremonies. It is a means of curing a sick person by aggregating him to the group of those who have had the disease and recovered; of introducing young men and women to the life of full members of the tribe; of bestowing on a young mother the solidarity of the group of mothers with strong and healthy children; of welcoming a widow, or widower, into the group of the widowed, and so giving them a new place in the society as a whole. The part water has come to have in their ceremonial life because of its extreme value in their economic life is also noteworthy. In addition to there being a great annual rain-making ceremony, water plays an essential part in many religious ceremonies, is endowed with a special protective power in some cases, and is considered extremely dangerous in others. Rain, as the source of water, is also held sacred, and the natural forces producing it are even personified and worshipped.

The Bergdama are of considerable interest, as they appear to be the most primitive negro people known, apart from the Congo pygmies. They are of medium height, strong, even coarse, build, with long rather thick skulls, prognathous faces, broad noses, very dark, even black skin, and all the features typical of the true West African negro. What their original language was is not known, for they have been so long enslaved by the Hottentots that they have completely adopted the Hottentot language. Yet in ceremonial their lives appear to have been but little influenced by the Hottentots, and among them there is found what appears to be a very important feature of many Bantu cultures, the sacred fire round which the whole life of the society centres. Each little group has a sacred fire which must never be allowed to go out, but which must be guarded day and night by the chief wife of the patriarch. Day by day, when the members of the group go out to seek for food, the head of the group and the old men sit guarding the fire, and as long as that is aglow and respected by all, the hunters and collectors will find food for the day. All game must be laid by the sacred fire, and certain portions of it must be eaten ceremonially by the elders of the group. Each kind of berry and root, as it ripens, must be brought to the sacred fire before it can be eaten. All good, all evil hangs upon the guarding of the fire from all impurities, which come from breaches in the regulations as laid down in the traditions of the tribe.

Racially the Bantu peoples present a great variety of types. They are fundamentally negro peoples, mixed with Hamitic, negrito and other types. The skin is usually less dark, stature lower, head less elongated, forehead flatter, prognathism less marked, nose generally more prominent and narrower than in the true negro. The Hamitic strain often shows itself clearly among the Zulu and allied tribes in a relatively narrow nose. The hair is uniformly of the ordinary negro type, the skin all shades from yellowish-brown to the black of the AmaSwazi, usually a reddish ground tint, dark chocolate colour being the prevalent hue. The Eastern tribes are on the whole taller and more dolichocephalic than the Central, while the South-western tribes are more typically negro than the rest.

The political organization of these peoples is well developed, and they have an elaborate system of laws regulating their social life. Among the OvaMbo blood revenge is still practised, but among the Central and Eastern tribes the tribal authority is supreme. All members of the tribe are regarded as belonging to the chief; an injury to them is, therefore, an injury to him, and compensation for death or injury must be paid to him. The AmaZulu and AmaXosa are renowned as fighting tribes, none of the rest being specially war-like; and among the former a strict disciplinary system was established by the great chief Chaka, who abolished the throwing spear, which is the typical weapon of this area, and introduced the short stabbing spear. By this reform he forced upon his warriors the necessity of coming to close quarters,

and from that time the Zulu became a dominant people and were able to found and develop a great military kingdom in South East Africa.

The initiation ceremonies at puberty of the Eastern and Central tribes are of some importance. The boys are initiated in groups, which are kept secluded in a special "lodge" for about three months, during which they are taught their tribal history, the moral and religious code of the society and its social etiquette. The ceremony itself consists in circumcision, performed by a special medicine man. These initiation "schools" are held every year in some tribes, in others at intervals of from four to five years. In each case the group of initiates is usually given a special name by which it is known throughout life. These groups play an important part in the tribal organization, and form the nucleus of the military system. The Zulu do not have initiation schools, nor do they practise circumcision, but the system of initiation groups has persisted in the formation at regular intervals of military regiments comprising boys of about the same age. Girls are also initiated in groups at the time of puberty, and are not considered marriageable till they have passed through the ceremony.

The Central tribes have remains of a tribal totemism. Each independent section of the people, which may at one time have represented a clan, has a *siboko* or laudatory name, taken from some animal or some natural phenomenon. In former times there was a definite ritual connected with the species of animal so used. Nowadays, however, the main division of the people is into patrilineal clans, and the possession of a common *siboko* is no bar to marriage. In the Eastern tribes all traces of totemism, if it was ever present, have disappeared. They are all divided into clans each with its own *isibongo* (laudatory name) which is generally the name of the ancestor from whom the clan is thought to have sprung. Marriage between people with the same *isibongo* is not permitted. Very often, however, a clan will split up, a younger branch taking some more immediate ancestor as its *isibongo*, while the older branch preserves the more ancient *isibongo*, and inter-marriage between the two branches is then permissible.

The OvaHerero clan system is a combination of the patrilineal and matrilineal systems. The people are divided in the first place into clans with matrilineal descent, called *eanda*, and then into clans with patrilineal descent, called *oruzo*. Every person belongs to the *eanda* of his mother, and the *oruzo* of his father. Both the *eanda* and the *oruzo* are totemic and exogamous. Each of these clan divisions has a different function. The *eanda* is associated with economic relationships, so that inheritance is in the female line. The religious life, on the other hand, is almost entirely connected with the *oruzo*, and is a developed form of ancestor worship, so that a man prays always to the ancestors of his father. Here again, the sacred fire is very prominent. At the chief's village the ancestors of the chief are worshipped, and represent the ancestors of the whole tribe. In addition the sacred fire is found in the kraal of each head of a family, lighted, in the first instance, from that of the chief. None of these fires must ever be allowed to go out. To this fire the women bring the milk each night and morning to have it blessed by the kraal head and the ancestors.

ARCHAEOLOGY AND ANTIQUITIES

The boundary between Negro Africa and "White" Africa, *i.e.*, Egypt and the northern and north-western portions of the continent, must be both conventional and provisional. The explorations of Reisner at Kerma in Nubia (between the third and fourth cataracts) and of Garstang at Meroe, have carried Egyptian influence so far south in the Nile valley that these sites, although inhabited by peoples of mixed culture, must from the archaeological standpoint be referred rather to Egypt than to the Sudan.

No such line of division exists in the west between the North African cultures and those of negro-land; indeed Gautier ("Études d'ethnographie saharienne," *L'Anthropologie*, 1907) has shown that there is good reason to suppose that the latter has advanced perhaps as much as 1,000 km. at the expense of the former, during the last 2,000 or 3,000 years. Moreover, Meroe itself does not accurately represent the southern limits of the mixed civilization to which it has given its name; some 12 m. south of Khartum on the right bank of the Blue Nile are the remains of Soba, a Meroitic site, later the capital of the Christian kingdom of 'Alwa (the Alut of the hieroglyphs), while Meroitic remains have been recently discovered 200 m. south of Khartum.

Yet Meroe, which lies in the neighbourhood of the 17th parallel of north latitude, may well stand as the main southern bastion of Egyptian influence, and the area with which this article will deal is that part of Africa lying south of 16° north, which will be divided into three provinces, eastern, western and southern.

The Nile-Congo watershed, a natural feature of geographical and ethnic importance, constitutes part of the dividing line between the eastern and western areas, which continues northwards along the broad ridge of relatively high land that roughly divides the territories of the Anglo-Egyptian Sudan from those administered by France. Thus the boundary line somewhat closely follows the western confines of Darfur, while south of the Nile-Congo watershed it coincides with the boundary between the Belgian Congo and British territories to the east, both eastern and western provinces being limited to the south by a line roughly following the 10th parallel of south latitude.

THE EASTERN PROVINCE

Palaeolithic Artifacts.—Here discoveries have so far been limited to the Sudan, Uganda, Somaliland and Kenya Colony, while surprisingly little is yet known of the early pre-history of even these territories. Except possibly in the extreme north, within a few miles of Halfa, no implement of River-drift type is known to have been found in the Sudan. This fact may be due to incomplete exploration, but is of some significance considering the abundance of specimens which have been found on the surface in Egypt and Libya, in Somaliland (where H. W. Seton-Karr has collected countless specimens of River-drift and Mousterian types), South Africa, and recently, in deposits, by Wayland in Uganda, though the majority of the implements he discovered are perhaps to be associated with the Le Moustier *facies* rather than that of the River-drift. Be this as it may, Wayland has collected Chellean hand-axes in gravels, considered of Pleistocene date, capping quartzite hill-tops some 300 ft. above the present level of the lake, and also implements of a well-developed Mousterian type, including "points, side-scrapers, flake knives, tortoise cores and tortoise points," as well as two typical side-scrapers in a cave under some five feet of cave earth. (A. A. Smith and E. J. Wayland, *Some Primitive Stone Implements from Uganda*; Uganda Protectorate, Geological Survey Dept., 1923.)

No typical Mousterian specimens have yet been found in the Sudan, but certain specimens collected from two sites, namely, Jebel Katul in north-west Kordofan, and Jebel Gule in Dar Fung, are considered by the Abbé Breuil to belong to the Mousterian period. So far as is known no implements attributable to the latter part of the Palaeolithic age have been found anywhere in the Eastern Province, certain pygmy implements which will be mentioned later being regarded as Neolithic. (C. G. Seligman, "A Neolithic Site in the Anglo-Egyptian Sudan," *J.R.A.I.*, vol. 40, 1910.)

Neolithic Age.—Evidence concerning the Neolithic age is furnished by a number of finds made on widely scattered sites in the Sudan, Uganda and Kenya Colony, and there are hints that in parts of Negro Africa, which nowhere had a Copper or Bronze age, stone implements may have persisted to within the last few centuries and the use of iron be quite recent. The distribution of the most typical of Neolithic implements, the ground stone axe, makes it necessary to refer to the conditions prevailing north of latitude 16 degrees. Unknown in pre-dynastic Egypt polished axe heads are common in Nubia, where a number have been found in pre-dynastic and early dynastic tombs. Many examples have come from Meroe, and specimens probably occur on every site of Neolithic date in the Sudan; they have been found, e.g., at Jebel Geili, 90m. east of Khartum, at Jebel Gule, and at Faragab in northern Kordofan; moreover, the grooves in the rock faces on which they were ground exist both at Jebel Gule and Jebel Geili, while stone axes of a peculiar type have been found in western Darfur by D. Newbold. These facts all support the idea put forward (*Rep. Brit. Assn.*, Pres. Address, Section H, 1915) that the ground stone axes of the Nile valley are of negro origin, a view consistent with their occurrence in the Congo, and, in relatively enormous numbers, in the Gold Coast. Perforated discs or rings, and hollow conical and spherical stones, all ground in the usual Neolithic style, have been found at Meroe, on Jebel Haraza (Kordofan) and at Jebel Geili, where stone discs and axe heads can be definitely associated together and with Meroitic potsherds.

Besides the types already alluded to, Jebel Gule yielded a large number of pygmy implements of quartz, carnelian and hornstone (similar to those found in South Africa and attributed to Bushmen), and there is reason to believe that this industry also existed at Faragab, where these "points" were used to bore the innumerable disc heads of ostrich egg-shell which cover the ground. The British Museum has a number of beautifully worked *dos abattu*

POTTERY FROM THE MOUNDS AT FARAGAB KORDOFAN

Figures 1, 2 and 3 are fragments of vessels; figure 4 is a reconstructed vessel of a type hitherto unknown in Africa; figure 5 is a bowl; figures 6 and 7, objects of unknown use

specimens of obsidian from the neighbourhood of Njoro in Kenya Colony; typical lunates, of jasper and of carnelian respectively, have been found in Uganda (Wayland), while to pass northwards of latitude 16°, G. A. Reisner (*Sudan Notes and Records*, vol. 2, No. 4, 1919) has found in tombs dating to the Egyptian 25th dynasty in Upper Nubia, perfect lunates of carnelian, in such numbers that there can be no question of their inclusion in the tombs being accidental.

This may close the account of stone implements which may be assigned to the Stone age cultures, so long as it is realized that the Neolithic certainly comes down to a period vastly more recent than the Neolithic of even northern Europe, and that in the Sudan, at least, it is overlapped by the Meroitic civilization, numerous outliers of which have been found, including those of Jebel Geili, another in the neighbourhood of the Makwar dam on the Blue Nile, notable for its Greco-Roman bronze vessels, and at Abu Sofian in western Kordofan. Although there is no evidence to show that they are Meroitic it will be convenient here to refer to the discoveries made by H. S. Wellcome at Jebel Moya near the Blue Nile and by Seligman in the mounds near Faragab, a village of sedentary Arabs some 20m. east of Bara in northern Kordofan. Though made about 1910 only the most meagre descriptions of the Jebel Moya discoveries have been published, although they are of prime importance to the history of the Sudan. Besides stone implements, were found beads and amulets, a number of scarabs and small plaques bearing Ethiopian and Egyptian cartouches, ranging from about 700 B.C. or perhaps going back to an even earlier date (*Brit. Assn. Reports*, 1912), while a paper by Prof. D. E. Derry (*Proc. 17th Internat. Congress of Medicine*, Sec. 1, Pt. 2, 1913), giving anatomical details of skeletons from graves at this site indicates that the inhabitants were tall negroes resembling in height and cephalic index some of the present day negroes of the hills of southern Kordofan (C. G. Seligman, *J.R.A.I.* vol. 40, 1910. Plate xxxv., figs. 8 and 9). At Faragab the mounds extend over acres and their surface and the areas between them are literally covered with disc beads of ostrich egg, fragments of bone debris and other foreign objects, including fragments of imported rocks. Two types of potsherds are of special interest, one consisting of a fabric bearing the impression of the string mat on which it was made (such mats are still used in the hills of northern Kordofan), and in this resembling the coarser wares found by Garstang in the graves of Meroe, the other oblong-oval in shape and rather shallow, often decorated with geometrical designs and produced at each end into a solid mass (handle?), its general appearance recalling that of many Melanesian wooden food bowls. This type seems to be hitherto unknown anywhere in Africa. The beads are of ivory, dolomite and scapolite; the single dolomite bead is definitely not of a type hitherto regarded as negro, while a single carnelian bead, if Egyptian, as no doubt it is, is regarded by Sir Flinders Petrie as certainly not later than 18th dynasty. (C. G. Seligman, "Prehistoric Site in Northern Kordofan," *Annals of Archaeology and Anthropology*, vol. 7, 1915.) The presence of many pieces of worked ivory is noteworthy. Of Meroitic monuments of any size, apart from those found at Soba, e.g., the "lamb" now in the Palace gardens at Khartum, the rock drawings discovered by Crowfoot at Jebel Geili, representing a king wearing the uraeus crown worshipping a rayed solar divinity, which may be taken to be of late Meroitic date, is of special interest.

Rock Drawings.—The rock drawings of the Sudan are in Kordofan and Darfur. Generally they are outlined in red or blackish pigment, but examples roughly graved on masses of granite also occur in the Jebel Haraza massif. Drawings with pigmented outlines are found on Jebel Haraza and Jebel el 'Afarit, and seem to form two groups. (H. A. MacMichael, "Rock Pictures in North Kordofan," *Journ. Roy. Anthropol. Inst.* vol. xxxix., 1909, pp. 562-68.) To the first belong rough but spirited sketches of men on horseback, camels and giraffes. The workmanship of the second group is rougher and much less vigorous; it includes representations of camels, men on horseback and men marching or dancing, carrying the small round Hamitic shield. This, together with their general resemblance to the "Libyo-Berber" rock pictures of the southern Sahara, indicates a comparatively recent date. Moreover, the work is faint and indeterminate, and there is no trace of graving; in other words the Neolithic tradition has not persisted. Probably the drawings are more recent than the stone discs and hollow conical and spherical stones found on Jebel Haraza, already mentioned.

It is as yet too early to estimate the significance of the objects found by D. Newbold (*Sudan Notes and Records*, vol. 7, 1924) on his recent journey from Bara in Kordofan to the international

boundary (long. 24° E.) between the Sudan and French Equatorial Africa. Evidence of former occupation of the country, now desert or the poorest steppe, was abundant, including cairns, pottery (some Meroitic), a small brick pyramid at Abu Sofian (16° N., 28° E.), and five ground axes of glauconite of hitherto unknown type from the Wadi Hawa. Drawings roughly incised on boulders, e.g., at Sobat el Hammad, showed tailed and phallic men, elephants, giraffes, ostriches, oryx, cattle and several other animals which could not be identified. At Umm Tersawen there were also a number of human figures, some tailed, some armed with bows. "At Abu Sofian two groups of pictures, obviously of the same date and 'school,' were within a day's march of one another. Here the drawings were incised on rough boulders, and were very numerous. Camels are shown literally in hundreds; giraffes and ostriches still appear; but the cattle dwindle in numbers, while the elephant is not represented, and the bowmen give place to men armed with spears and carrying shields." The latter armament appears to bring these drawings into the Libyo-Berber class.

Megalithic Monuments.—Megalithic stone monuments occur in the Sudan, some of the present day, others certainly recent, a few apparently of some antiquity, though as to these our knowledge is of the slightest. In the northern Sudan the Beja tribes surround the graves of their dead with a circle of upright stones; round some of the older graves individual stones were occasionally taller than a man, and it is probably the persistence of such stones after their smaller neighbours have disappeared that has given rise to monoliths such as that some two metres high (to which the Prophet, according to the accepted tradition, tied his horse) overlooking the Khor Arab near the Sinkat-Erkowit road in the Red Sea Province.

Another monolith of much the same dimensions has been described and figured by J. W. Crowfoot from Assarema Derheib, inland from 'Aqiq (*Geog. Jour.*, May 1911), and in this instance there seems nothing to suggest its origin in a Beja grave. Farther south megalithic monuments have been reported from the Madi, while stone circles are made by the Lotuko-speaking tribes wherever stone is abundant, as squatting places for the men, though in no case could evidence be obtained of stones large enough being carried even a few miles. Again, although megalithic structures occur among the Lotuko and the Bari-speaking tribes of Mongalla Province, it is certain that some are recent erections over graves, e.g., the examples discovered by E. E. Evans-Pritchard among the Moro of the eastern Bahr el Ghazal. Although megalithic neither in structure nor form there is a type of stone monument some 80 ft. long and about 5 ft. high occurring in some number in the neighbourhood of Erkowit. These (*Jour. Egypt. Archaeology*, vol. 2, 1915) are constructed without any cement or mortar; the face consists of a limiting wall of more or less flat slabs of local rock, while the spaces between the containing walls are filled in. Each monument may be considered as of three main elements, viz.: (1) an oblong rectangular portion, (2) two oval masses, to each of which is attached an expansion shaped somewhat like a fish's tail and (3) the curved walls uniting the other elements. Their orientation seems to have been toward the rising sun, while each oval element is interrupted at a constant point in its circumference by the interposition of from two to four upright slabs. There is no chamber or space behind these stones, but from their constant presence and the uniformity of their position it is obvious that they must have had a perfectly definite significance to the builders, indeed they recall the false doors of Egyptian monuments. J. W. Crowfoot found human bones under the filling of the rectangular portion but no objects with them. They may provisionally be regarded as mediaeval, but as antedating the spread of Mohammedan influence which was becoming dominant towards the middle of the 15th century.

Abyssinia.—Although the monuments dating from the 4th century A.D. discovered at Aksum by Theodore Bent (*The Sacred City of the Ethiopians*, 1896) are still the most important, interest will for some time tend to centre round the many new discoveries of "prehistoric" date, including some presumably of no great age, made by the Rev. Father Azais.

Littman, the leader of the German expedition to Aksum, holds

that the carved and decorated monuments generally termed "obelisks" are in fact stelae (of huge dimensions it is true, e.g., from 15 to 33 metres) and therefore each to be regarded as part of a tomb, a point of view rendered the more probable by the presence at their base of stone slabs, often carved, which have every appearance of being altars. All this seems to imply a cult of the dead, but, apart from this, inscriptions dating from the 1st and 4th centuries record the names of the gods of the Semitic conquerors of northern Abyssinia. A Greek inscription of Adulis, no longer in existence but copied in the 6th century by Cosmos Indicopleustes, states that the king of Aksum of the 1st century, who caused this record to be cut, worshipped Zeus, Ares and Poseidon. A later document of King Aizanas (about A.D. 350) is in Greek, Sabaeian and old Ethiopic. An analysis by Littman of this inscription, together with one dating from about a century later, indicates that worship was rendered to Heaven, Sea and Earth, together with Mahren "who begat the King," the latter being identified with Ares. Other monuments include rude monoliths, some ornamented with bands, and a most spirited rock-carving of a lioness in low relief.

The recent work of Father Azais shows that Abyssinia is remarkably rich in stone monuments, of types hitherto unsuspected. The following is derived from the well illustrated, but summary, account of the rev. father's investigations given by A. Kammerer (*Essai sur l'Histoire antique d'Abyssinie*, Paris, 1926). Most of the discoveries were made in an area stretching southwards from Addis Ababa beyond Lake Zwai to the neighbourhood of Lake Margherita. Large tumuli, some surrounded by a circle of megaliths, and a number of dolmens in excellent preservation, were found about 100 m. south-east of Harrar, i.e., on the edge of the Ogaden Somali country. These dolmens are said to be of the same general type as is found in western Europe. One which was systematically explored yielded, besides human remains, potsherds, a silver ring and a heavy metal bead.

Menhirs are particularly abundant in Sidamo Province, where they are generally of dressed stone, phallic in form, and may attain a height of 20 feet. A number of menhirs with anthropoid designs in low relief were found near Silte, the capital town of Guragwe. Further south, not far from Lake Margherita, statue menhirs carved in the round occur. These may show geometric designs which suggest tattoo or cicatrices, while to the west and north-west of Lake Zwai, hundreds of short stout uprights of dressed stone, "stunted menhirs," have been discovered, each bearing in relief representations varying in number from one to 13 of a short broad-bladed sword which vaguely suggests the short Roman sword. In this district, too, were found several stele bearing Arabic inscriptions in the Nasri script.

Recent Discoveries in Kenya and Tanganyika.—Important (and at the time of writing unpublished) discoveries have been made in East Africa. In 1913 a human skeleton was found by Dr. Hans Reck at Oldaway, in northern Tanganyika, on the borders of the Serengeti plain. This lay some three metres deep, in undisturbed deposits of the last Pluvial period, associated with a fauna of which more than 50% represents extinct species, including *E. antiquus Reckii*, *Hipparion* sp., and an extinct sheep (*Pelorovis oldawayensis*). The skull from this skeleton is said to resemble that from Elmenteita, found by L. S. B. Leakey, whose important discoveries in Kenya in the neighbourhood of Lake Nakuru may provisionally be summarized as follows:—

A partial excavation of a flat-topped kopje at Eburu yielded crouched burials of a people with long slender limb bones and long narrow skulls, probably Negro-Hamitic. There was an iron toe-ring on one of the skeletons. At Nakuru a series of forcibly contracted burials was found along the side of a cliff; the skulls which are not negro—it is too early to discuss whether they are in any degree negroid—are long and massive with a long face and well developed and narrow nose. The muscular impressions are well marked, the longbones long and relatively slender. With these skeletons were found obsidian microliths, including lunates, small *dos abattu* blades, stone bowls and mortars, grinding-stones, pottery, simple bone tools and two beads of foreign origin which may possibly date about 2,000 B.C. At Elmenteita, near the Makalia

river, there were found bones, including skulls, probably representing burials disturbed by flood, and some of these bones are definitely fossil. Here the skulls are of more than one type, (1) strongly built, dolichocephalic, and, apart from the lower jaw, somewhat resembling the Combe Capelle skull, (2) smaller, brachycephalic, represented only by women. The associated industry consists of fair-sized flakes, lunates and end-scrapers of obsidian, ostrich-shell beads and pearl shell pendants, as well as at least three types of pottery. Besides the effects of flood this site was disturbed some ten years ago, so that the original stratification may have become confused and the associated objects be of different ages.

THE WESTERN PROVINCE

Palaeolithic Remains.—It is only recently that stone implements of River-drift type, and therefore to be regarded provisionally as of Palaeolithic age, have been discovered in West Africa. In the British Museum there is a series of massive implements of Chellean type, consisting of quartz porphyry, which on the surface have weathered to the softness of chalk. These come from the alluvial deposits of the Bauchi plateau, as do a smaller number of implements of Mousterian type of the same mineral, and one very steep end-scraper of a more homogenous stone showing no surface weathering. (These implements are described by H. J. Braunholtz in *Occasional Paper No. 4* of the Geological Survey of Nigeria.) There is also in the national collection a number of short stumpy implements of Drift type of a reddish quartzite, for the most part with unworked butt, found on the golf links of Accra (Gold Coast). Similar specimens have been found in the local gravels, the actual specimens in the museum having apparently been washed up from the beach.

Neolithic Age.—Polished axe-heads of ordinary Neolithic type are by no means uncommon in West Africa and the Congo valley. They are found in Northern Nigeria, especially in the Bauchi Plateau gravels, where it is said that they overlap to some extent the Drift types. They are, however, of a different stone, for the most part of dolerite. In the Gold Coast Colony they are found in large numbers, as are perforated quartz discs, while a few bossed spheres about 2 in. in diameter, of anomalous appearance and unknown use, have been recovered. A collection of Neolithic implements from Calabar include stone axes, unusual in that they possess a definite tang for hafting.

Under the title "Tumbakultur" Oswald Menghin (*Anthropos*, 20, 1925) has described a culture characterized by series of implements, widespread in the Lower Congo area, which he tends to approximate, though with difficulty, to the Campignian of Europe. Be this as it may, Menghin finds a long series of artifacts passing insensibly from implements of coup-de-poing type, Campignian *pics*, flattened ovates of almost laurel-leaf type, to notched and roughly cruciform spear or arrowheads, some, though larger and coarser, irresistibly recalling the "freak" forms from Breonio in Italy. Apart from these, many ground stone axes have been found in the Congo area.

Megalithic Monuments.—Megalithic monuments are distributed widely in West Africa in the form of stone circles and standing stones. In Gambia both classes of monuments have been carefully described by the late Henry Parker in a paper published after his death (*Jour. Roy. Anth. Inst.*, vol. 53, 1923):—

"The circles themselves are generally found in groups or clusters comprising from two to nine, but single circles are met with. With one possible exception there are no uncompleted circles, except those formed by concentric outer pillars standing round an inner circle. . . . The groups of circles are arranged in single straight lines; in nearly parallel lines consisting of two, three or four circles; or in pairs; but never in triangles or pentagons. Many stones are prostrate and . . . almost invariably these fallen pillars . . . are at least partly buried by the soil. . . . Some have their upper face almost level with the ground, and as a rule the others are half or three-quarters covered by the earth. . . . Superficially considered this is the only indication of the age of these structures, and . . . it would be of great value if we knew the rate of elevation of the soil. Without such knowledge it is only possible to draw the conclusion from this evidence that both

the circles and the menhirs must have been erected many centuries ago.

"In addition to the concentric outer pillars, there are several instances where the outer pillars are arranged on the eastern side of the circle in a straight line, or even in two parallel lines, in a north and south direction. Such lines are invariably to the east of the circle. . . ."

The circles are considered sacred to the Earth Spirit, and ceremonies are performed in them to propitiate the latter, as also for the protection of the crops. It does not, however, appear that Parker excavated in them, and their date and purpose must be left for further exploration, though in the light of information received on the spot the contents of the circle (human remains, spearheads, copper armlets) dug by J. L. Todd and G. B. Wolbach (*Man*, No. 96, 1911) suggest that in recent times these monuments were the sites of sacrifice for success in warfare.

In some of the northern villages of the Cross River Division of Nigeria, *i.e.*, in the villages of the Akayu, Indem and Atam districts (on the left bank of the Aweyong river) there are stone circles, the stones often more or less conical and carved to represent the human body from the waist upwards. These have been described and figured by C. Partridge (*Cross River Natives*, 1905, pp. 268-599); the navel is specially prominent, and cicatrices seem to be reproduced. At Agba village the circle surrounds an old tree, and the grove of the great chief who erected the circle. The tree is sacred, and of the stones it was said by the ancestors "these stones are your forefathers, your very great chiefs; every year you must sacrifice to them" (p. 271).

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

WOMEN SERVE AS CARRIERS IN AFRICA, COVERING 35 MILES A DAY

Beads.—In the past, claims of high antiquity have been made on behalf of the so-called "aggry" beads that have been found in West Africa. Yet as stated by Sir Hercules Read, with the single exception of the necklace to be discussed immediately none of these beads shows features not to be found in mediaeval or later beads from the factories of Venice. The necklace, presented to the British Museum by L. P. Davies, was obtained from the grave of "a renowned chief" at Mansu, a town on the route from Elmina to Kumasi. It is described in detail in *Man* (1905, 1).

For present purposes interest centres in some 20 beads of crystalline glass, irregular-faceted, and especially one bead of crystalline glass moulded like a mulberry. Sir Hercules Read writes of these as being in a state of iridescent decay, the surfaces being in many cases deeply pitted and presenting exactly the same appearance as beads of the same kind from the Mediterranean area. He points out that the crystalline glass in this necklace is identical in appearance with those from the tombs at Kameiros in Rhodes, dating from the 6th century, and goes on to suggest, but "without insisting too strongly on this point," that here are "glass beads of classical style found for the first time in West Africa, and presenting features that in point of date may justifiably be associated with the name and time of the Carthaginian Hanno, a name often invoked when objects of indeterminate age are found on the African coast."

Though probably not of any great age, reference must be made to the soap-stone carvings of human heads or figures (occasionally animal figures) found in the ground, sometimes apparently in pits, in certain districts of Sierra Leone, where they are used as agricultural charms. These figures are for the most part roughly carved, the work being well within the scope of present-day Africans, and Joyce (*Man*, No. 57, 1905, and No. 40, 1909), points out that there is really no reason to see in them—as has been proposed—evidence of foreign, *i.e.*, Egyptian or Carthaginian influence. The objects described by Frobenius from Old Ife (*The*

Voice of Africa, 1913, vol. i, chap. 14; "The Archaeological Finds"; and *Das Unbekannte Africa*, Munich, 1923), the ancient capital of the Yoruba, are also probably of no great age; there do not seem to be any which the 16th century Benin civilization might not have produced.

Possibly of about the same date are a number of bronze and silver objects, now on deposit in the British Museum, from a sandy mound (no doubt a grave) at Tumuni in the Sokoto Province of Northern Nigeria. Sir Hercules Read holds that they exhibit features and analogies which are unusual in negro African metal work, pointing to artistic or commercial relationship with the culture of the Mediterranean area, doubtless at a period remote from the date of the manufacture of the relics themselves.

The most important pieces are a bucket with incurved sides and lugs, and a barrel-shaped armlet (?) for wear on the bicipital region. The lines and casting of both, and the geometrical patterns tooled on their surfaces, are good and careful work. While the find as a tomb-group may date to A.D. 1480, as suggested by H. R. Palmer, yet, as stated by Read, they are of unusual interest from the analogies they present with the early Mediterranean cultures, and we may have here a distant echo of the early art of the Bronze age. At the same time there is no reason to think that the actual objects are anything but local productions, though they may differ from those of more recent date.

THE SOUTHERN PROVINCE

Palaeolithic Implements.—Artifacts of rude Chellean type, often larger than the corresponding implements of western Europe, are found over the greater portion of South Africa, nor does there seem to be any reason why these should not be regarded as true palaeoliths perhaps of an age comparable to those of Europe. One of the most satisfactory finds of this order is constituted by a considerable number of implements of chalcedony, quartzite, etc., exactly similar to types characteristic of the River-drift Period of western Europe and Great Britain, associated with and evidently forming part of ancient terrace gravels deposited as drifts by the Zambezi (in the neighbourhood of Victoria Falls) at a remote period. The position of these terrace gravels and surface drifts in regard to the Batoka Gorge indicates their real antiquity, since they must have been deposited by the river when the latter was covering the old valley floor more than 400ft. above its present level. Here Henry Balfour excavated several implements from undisturbed gravel deposits at depths varying from 6in. to 2ft., some greatly water-worn and heavily patinated.

Recently A. J. H. Goodwin ("South African Archaeology," *Man*, 1927, 14, and "Capsian Affinities of S. A. later Stone age Culture," *South African Journal of Science*, vol. xxii., 1925) has summarized South African history on the following lines:—

The terms Palaeolithic and Neolithic are dropped, the two main periods being termed the Earlier Stone age and the Later Stone age, Péringuey's name for the main *coup-de-poing* culture of the Earlier Stone age, the Stellenbosch industry, being retained. A second culture, the Victoria West industry, centres round Victoria West in the south-central Karroo, running north into the Free State and west to Nakob on the S.-W. African border; the *coup-de-poing* occurs, but the main implement appears to be a core similar to the European Acheulean tortoise-core, but some 8in. or so in length. It is not clear whether core or flake was the desired element, but secondarily worked flakes of this industry have not been found. The last culture of the Earlier Stone age is that of Fauresmith in the Orange Free State, with a flake worked to resemble a *coup-de-poing* as the characteristic tool.

There is no evidence of the Earlier Stone age developing into the Later Stone age, indeed they probably overlapped. The earliest industry of the Later Stone age is that of Still bay (near Mossel bay) covering most of the eastern part of the Union and extending into the Free State and to Okahandja in South-West Africa. This culture somewhat resembles the Solutrean of Europe, with lanceolate implements (usually small) as well as tanged forms, sometimes with serrated edges.

The Still bay culture was followed by two probably contemporaneous industries which extend into modern times, termed from

sites in the Orange Free State the Smithfield and Wilton cultures respectively. The Smithfield culture includes end-scrapers, thumb-nail and horse-shoe scrapers, trimmed points (of Chatelperron type), handpicks, bored stones, ostrich eggshell beads, ground stone rings, pottery and human remains. The human remains are of the "Bushman" type, and in a general way this culture is similar to the Capsian or the Aurignacian of Europe. The Wilton industry is very similar; the chief implements are pygmy lunates, thumb-nail, and end-scrapers, as well as geometrical forms; the pottery is similar to that of Smithfield; bone arrowheads and link-shafts occur; burials are flexed, with skeletons of the same general type as the Smithfield specimens. Slate "palettes" are also found, and the culture is definitely associated with the cave paintings. Goodwin considers this culture as identical with the last phases of the Capsian of Spain and North Africa, a point of view confirmed by I. Schapera ("Some Stylistic Affinities of Bushman Art," *South African Journal of Science*, vol. xxii. Nov. 1925, pp. 504-15), who, as the result of a careful comparison of European Palaeolithic and Bushman art concludes that the Capsian art of Spain shows most affinity with that of the Bushmen.

Information supplied by Goodwin indicates the existence of a true Mousterian—the Glen Grey industry—with high-backed as well as the more usual flat points similar to those found in North Africa and Europe, while in the Later Stone age the recent discovery at Howieson's Poort of a number of true graving points (*burin*) is important, both in itself and as further suggesting contact with the north.

Pottery.—It is not clear that examples of pottery of any considerable age exist. Those figured by Péringuey (*Annals of the South African Museum*, vol. viii, 1911), provisionally assigned to Bushmen, Strandloopers and Hottentots, are of the rudest type, predominantly ovoid with conical bottoms, sometimes ornamented, the kneading and baking being very poor.

The Bushmen.—No apology seems necessary for considering the "archaeology" of the Bushmen with that of the kindred Strandloopers (no longer to be regarded as a distinct race, the name describing a mode of life and not implying a constant physical difference), for even though the former are not utterly extinct, the few survivors no longer pursue their characteristic arts of painting and graving on rock. It is generally admitted that the Bushmen stock came into South Africa from the north, and Stow was of the opinion that there were two great divisions, each with its characteristic mode of life and art, viz.: (1) cave-dwellers (painters), and (2) kopje-dwellers (sculptors), the latter producing their works by "pecking" the rock face on which they worked. This view does not seem to be generally accepted, perhaps it only emphasizes differences in technique due preponderantly to environment.

The paintings of the Bushmen, naturalistic monochrome and polychrome studies of high artistic merit, for the most part record the animals which they hunted and upon which they subsisted. But paintings of the carnivora are not absent, and cattle raids, dances and magico-religious (?) scenes are also portrayed. Belonging no doubt to the latter class are the fairly numerous examples of animal-headed human figures—representations of masked dances—not to be confused with the wearing of animal skins as a hunting ruse to admit approach to the game, as in the famous picture in the Hershel district of Cape Colony of a Bushman wearing an ostrich skin while stalking a flock of these birds.

The character of Bushman paintings has been well summed up by Henry Balfour:—

They are "remarkable not only for the realism exhibited by so many, but also for a freedom from the limitation to delineation in profile which characterizes for the most part the drawings of primitive peoples, especially where animals are concerned. Attitudes of a kind difficult to render were ventured upon without hesitation, and appreciation even of the rudiments of perspective is occasionally to be noted, though only in a crude and uncertain form. The practice of endeavouring to represent more than could be seen at one time . . . is far less noticeable in Bushman art than might have been expected from the rudimentary general culture of these peoples, and one does not see instances of *both* eyes

being indicated upon a profile face, or a mouth in profile on a full face. . . . The colours were usually laid on uniformly over the surface which they individually covered, but a shading off is sometimes exhibited." (*Bushmen Paintings*, 1909, p. 9.)

Dr. K. M. Barnard points out that examples similar in execution to those described by L. Péringuey (*Trans. S. Afr. Philos. Soc.*, 16, 1906, and 18, 1909) have been discovered at various places in South-west Africa, the farthest north being in the Grootfontein district. In addition to the usual animals there are representations of the human foot, and the spoor of various bucks, while from the position in which these latter occur the explanation that they are "sign-posts" to water cannot be maintained.

Major F. J. Bagshawe (see *Man*, 1923, 92) has discovered in Tanganyika Territory rock-paintings of Bushmen type of so high an artistic quality that their origin can only be referred to this race, an extension northwards which goes well with the distribution of the Bushmen *kwe* (digging-stick weight), of which specimens, known in Tanganyika, have been discovered in Uganda (Wayland) and even among the Bari of the Southern Sudan (Seligman). The Tanganyika rock-paintings include an eland, cow, ostriches, giraffe and antelope.

Strandloopers.—The Strandloopers are a people of whom, apart from their skeletal characters, we know little, though concerning these there is a fair volume of reliable if not always consistent data. Their cultural attainments may be judged, *e.g.*, from the remains found in the caves and rock-shelters of T'zitzikama cliffs, about 100 m. to the west of Port Elizabeth. One of these shelters explored by F. W. Fitzsimons (described by Sir Arthur Keith, *The Antiquity of Man*, I, 1925), contained deposits some 30 ft. deep. The lower 5 ft. and the upper 6 ft. were sterile; below this latter layer was a stratum some 7 in thickness in which numerous Strandlooper burials were encountered amidst remains of fireplaces, broken pottery, implements and ornaments in stone and bone. Then came the third stratum, over 6 ft. in thickness. While removing this stratum and working at a depth of 15 ft. below the original floor of the shelter, Fitzsimons found graves containing remains which differed from those he had met with in the stratum above. Unfortunately the bones in the lower stratum were imperfectly preserved. The graves had been partly protected by slabs of stone some of which had been rudely engraved with human figures. There were lumps of red ochre, necklaces of shell and bone and tools of stone and bone. In a still deeper stratum, also about 6 ft. in thickness, there were traces of burials and hearths, the human remains being fragmentary, but considered to belong to individuals of the Boskop type.

Mediaeval Remains in Rhodesia.—The conclusions of D. Randall-MacIver (*Mediaeval Rhodesia*, 1906) that the Zimbabwe and similar ruins in Rhodesia are negro in origin and modern in date, though not generally accepted in South Africa, have not been disproved. For though there is no inherent improbability in the early Semitic origin of these ruins, it seems unnecessary to seek a foreign colonization where the facts in no way contradict a local origin. No authentic inscriptions have been found, and no objects discovered in the Great Zimbabwe, around which the controversy has chiefly centred, need be more than a few centuries old, while those that are not foreign imports (porcelain, etc.) are of African type. Moreover, a re-examination of the evidence, including unpublished material in the library at Lisbon, has led Father Schebesta (*Mitt. der Anthropol. Ges. in Wien*, 1922-23) to the conclusion that not only is the Zimbabwe a product of the indigenous kingdom of Monomotapa described by the Portuguese, but that its builders culturally resembled the Baganda, and probably certain other of the more advanced peoples of Central Africa.

For bibliography, see the references in the text. (C. G. S.)

NORTH AFRICA

The archaeological documents of north Africa reflect the cultural conditions recorded in its ancient history, the imposition of successive alien civilizations by dominant Mediterranean Powers upon a receptive but resistant native population. The ancient invaders were (under their political names) Phoenicians, Greeks,

Romans, Vandals and Byzantines; the Arab invasions, which began in the 7th century A.D., belong to modern history.

Native Cultures.—The native Libyan and Berber (*q.v.*) elements, whether aboriginal or not, have persisted without visible change from the prehistoric period to the present day. Their most ancient handiwork is represented by stone implements and simple pottery found in cave-dwellings, figures of men and animals engraved on rocks, some fortress-walls and many sepulchral monuments of megalithic type, square and circular dolmens, cairns and cromlechs. This material is related on the one side to the most primitive remains of Spain and south France, on the other side to those of Egypt and Crete; but while neolithic culture in the Egyptian and European areas was superseded in the prehistoric age, the African stone implements seem to have remained in use in certain districts until very recent times. It is seldom possible to date these monuments even approximately. The Berber language was inscribed on stone, often in conjunction with Punic and Latin texts, in a local alphabet which is still current among the Tuaregs (*q.v.*) of the Sahara. Beside this backward element there was in historical times an urban population more or less civilized by contact with Greeks and Semites; but it does not appear to have developed a distinctive art. Its surviving monuments are mostly sepulchral: most notable are two pyramidal structures near Tipaza (anc. *Tipasa*) and Batna in Algeria. The former, called the Tomb of the Christian Woman (*Kbor er Roumia*), is evidently a royal tomb and perhaps that of Juba II., the philhellene king of Mauretania in the time of Augustus. The other, called the Medracen (*Madghasen*), is older, and may be the tomb of Massinissa, the Numidian ally of Rome in their last war with Carthage. Both are low cones of stepped masonry set on cylindrical bases which have cornices borne by engaged columns; their diameters measure about 200 feet. The form may have been derived from the native cairns, but it closely resembles the monumental tumuli of Italy and Asia. The architectural orders are Greek, with some archaisms and other peculiarities that indicate Punic influence.

Phoenician.—The Phoenician settlement, of which Carthage was ultimately the chief city, is assigned to the 12th century B.C., but its earliest known remains are not older than the 7th. At the time of its fall in 146 B.C. Carthage controlled nearly the whole of what is now Tunisia, and was in touch with the native kingdom of Numidia on the west, and through the Phoenician territory of Tripolitania with the Greek colonies of Cyrenaica on the east.

Nothing is left of the Punic city of Carthage and very little of its Roman successor, the colony which was founded as the capital of Africa after the destruction of the original Carthage. But its site is indicated by a zone of cemeteries, which lay outside the walls. It is a large semicircular area bounded on its short side by the sea; its central point, the modern St. Louis' Hill, was certainly the Punic citadel, the *Byrsa*, and the port was south of this, near the place where two lagoons now lie. These agree perhaps fortuitously with ancient descriptions of the commercial and war harbours, the latter having the Admiralty Island in its midst; but the coast has greatly changed even in the last century, and ancient lines of sea-walls and quays have been identified on the outer coast. The curse that Rome invoked upon the Punic site has operated on its own foundation. After the Arab sack, the city was abandoned by the conquerors, and became a quarry for Mediterranean masons of all later ages. The cathedral of Pisa is said to have been built with stones of Carthage. A few of the larger structures can be traced. On the *Byrsa* is a temple of Aesculapius; in the western plain, an amphitheatre; on either side of the northern hill, a theatre and an Odeum; in the eastern plain, the baths, better preserved in the Arab name of the locality (*Dermesh*) than in its soil. The waterworks have fared better: there are great vaulted reservoirs at Dermesh and La Malga, fed by an aqueduct from a copious source at Zaghouan, 100 miles away.

The Punic graves that have been found are not older than 700 B.C. They are mostly double chambers approached by shafts; burials were often made in stone coffins with lids carved

as recumbent human figures. There are numerous grotesque clay masks which were placed in the graves to keep evil spirits away. Personal trinkets and jewellery are the other furniture.

In a sanctuary of Baal at Dougga (*Thugga*) birds' bones were buried in jars. This temple, which was dedicated to Saturn under Roman rule, was enclosed in a square colonnade. A temple of Tanit-Caelestis at the same city stands in a semicircular court. A mausoleum built there in the 4th century B.C. and recently reconstructed was designed in Graeco-Phoenician style, and bore a bilingual inscription in Libyan and Punic. The art of Carthage was rapidly hellenized, probably by contact with Greek colonies in Sicily rather than with those of Africa.

Greek.—The largest Greek city in Africa was Cyrene, one of the greatest cities of the Greek world. Yet its famous and conspicuous site was almost inaccessible until the 20th century. In 1861 two young officers of the British forces at Malta, R. Murdoch Smith and E. A. Porcher, found and identified the temple of Apollo, sent to England a large series of sculptures, now in the British Museum, and excavated at other points outside and inside the city, but could not stay long enough to explore its topography more definitely. An expedition equipped by the Archaeological Institute of America made a good beginning in 1910, but met with organized hostility among the natives, and before its second season had begun the country was seized by Italy. All archaeological work in Cyrenaica and Tripolitania has since been directed by the Italian Government. The results at Cyrene show that the Roman city occupied the two hills that are the landmarks of the site. The western hill was the Greek acropolis and contained the agora; on the eastern hill is a Doric temple and a stadium; the residential quarters lay in the dividing valley and on the south-west slope of the eastern hill. At the north end of the valley, outside the city wall, the sanctuary of Apollo stands on a partly artificial platform below the fountain, Kyra. The low and narrow channel of this famous spring can be followed for a quarter of a mile inside the mountain; ancient inscriptions are scratched and moulded on the clay that covers its walls, and the mouth of the channel is an open chamber cut in the face of the cliff. Rows of chamber-tombs with elaborate architectural fronts are cut or built in the slopes of the plateau. It seems that the city when fully excavated will be another example of the conventional Roman splendour which is the characteristic element in north African antiquities; but the sanctuary is a new feature, preserving its original plan, and important remains of the Greek structures have been found beneath the Roman ornament. The sanctuary is a walled precinct like that of Delphi. It contains the temples of Apollo and Artemis, each with a great altar in front, and smaller shrines of lesser deities. A curious adjunct of the Artemisium is an underground Nymphaeum, apparently for purificatory rites. The Apollo temple has treasure-cists sunk in its floor. In Roman times two bath-establishments were intruded on the terrace, from one of which some 20 marble statues were recovered, including a headless Aphrodite now in the museum of the Terme at Rome. The rest of the material from Cyrene is at Bengazi. On the west side of the precinct is a Greek theatre. The Sacred Way leads from the sanctuary past the fountain to the agora, a colonnaded area of the usual Roman type containing the provincial *capitolium* and other official buildings. Among the Greek survivals here are the *heroön* and a small circular structure which was the tomb of the first Battos, founder of the city and of the dynasty which ruled it. The round tomb is apparently the base on which stood a column depicted on some Cyrenaic coins. Curious sepulchral monuments found in the rock-tombs are sculptured busts with heads in which the face was indicated by painting, or with tapering columnar necks instead of heads. Greek art is rare: a few archaic votive statues have been found and further excavation will doubtless produce others. The archaic strata should also help to determine the origin of the so-called Laconian or Cyrenaic pottery. (See POTTERY, *Greek*.) A small bronze head of a bearded man (5th century B.C.) has been found by the Italians, and a marble head of Athena (said to be 4th century) was excavated by the American expedition, but the finest work of art from Africa is a Hellenistic bronze head of a young Berber,

which was found by Smith and Porcher in the temple of Apollo. It is also an anthropological document of great value. There are other Hellenistic pieces among the numerous marble statues from Cyrene, but the sculpture here as in other north African cities is generally of Roman date. The other cities of Cyrenaica have produced Greek terra-cotta statuettes and painted vases, mostly from tombs; among the vases are several oil-jars which were prizes in the Panathenaic games. The Punic colonies must have contained examples of Greek art, and the Mauretanian capital of Juba II. at Cherchel (*Caesarea*) was decorated with imported statuary, some fragments of which survive. Some good examples of Hellenistic sculpture have come from the sea. They were found in a sunken ship which was located in 1907 off Mahedia near the Lesser Syrtes, and are now in the museum of the Bardo at Tunis. The most important is a bronze herm signed by Boëthos of Chalcidion. There are many decorative bronzes belonging to furniture, and parts of large marble vases and candelabra in Neo-Attic style. The ship's hold was divided into three compartments, and the deck was laden with marble columns. The date of the wreck is placed in the 2nd century B.C. Two large bronze statuettes, a standing boy and a seated girl, came from the harbour of Bône (*Hippo Regius*) in 1912, and a bronze horseman, said to be of the 5th century B.C., was excavated at Ksar Farun (*Voullis*) in Morocco.

Roman.—Most of the Roman cities are comparatively late foundations. The civilization of Africa was never finished, and its imperial history is a record of continual progress southwards and westwards from the original province to the Sahara and the ocean. Even the older Greek and Carthaginian cities, such as Cyrene and Thugga, and the native capitals of Cirta and Caesarea, were converted to the metropolitan Roman model in the mature imperial age. But the ordinary African township was a mushroom growth, built to an emperor's order and peopled with colonists from the army and the countryside. As the citizens were Romanized by the gift of the Latin name, so the dignity of their city was asserted in its public buildings. Theatres and baths were erected and adorned by the munificence of wealthy Africans, to whom and to Roman landowners and their agents belonged the luxurious villas that are scattered through the country districts. But the urban population in general was meanly housed. The best example of a new city is Timgad (*Thamugadi*) in south-east Algeria (*Numidia*), north of Mt. Aures. It was founded by Trajan as a colony in A.D. 100, and built by military architects and labour from the Legion III: Augusta, whose discharged soldiers were the colonists. The site is laid out on the lines of a military camp, a square cut up into small blocks (*insulae*) by intersecting streets drawn parallel to the enclosing ramparts. A monumental gateway (the so-called triumphal arch of Trajan) stands in the middle of the west side. At the central crossing of the two main streets (*cardo* and *decumanus*) is the *forum*, occupying the space of eight *insulae*, and next to the forum is a theatre. Other public buildings now inside the ramparts are a market-place, a library and baths. The city rapidly outgrew its walls; the later *capitolium*, more baths, a larger market, another triumphal arch, pagan temples and Christian churches were built outside, and as the town grew its formal character was lost. The camp in which the legion itself was permanently quartered is *Lambaesis*, 20m. W. of Timgad. It was established in the first half of the 2nd century, and consists of a fortified square intersected by the two main roads and containing military offices, barracks and baths. A great part of the site is covered by a modern prison. To the south lies the town that attached itself to the legion, entered through monumental arches and equipped with the usual apparatus of capital and lesser temples, theatres, amphitheatre and baths. *Lambaesis* is a unique example of a permanent camp. *Cardo* and *decumanus* are paved with stone and bordered with colonnades, and south of their intersection stands nearly to its full height the four-arched entrance to the *praetorium*, leading to a court with porticoes behind which are the headquarters' offices, legionary shrines and armouries.

Other municipal foundations were built on the same model as Timgad, but not always with the formal plan that can only be

achieved on an empty site. The best preserved structures are probably those of Lebda (*Leptis Magna*) in Tripolitania. This was the native city of the emperor Severus, and was magnificently adorned by him. It has been covered by wind-borne sand, which overthrew whole walls with its weight and at the same time buried and protected their ruins. But many walls and columns are still standing with cornices and entablatures intact. At the other end of the Roman dominion, in Morocco, lies Ksar Farun (*Volubilis*) near Meknes, a solitary outpost of classical culture in a barbarous land. A triumphal arch and the remains of a basilica were visible before its excavation. The site was largely cleared by prisoners of war in 1915. Other well-preserved or excavated cities are, in Algeria, Jemila (*Cuicul*), Khamissa (*Thubursicum Numidorum*), and Tipaza (*Tipasa*); in Tunisia, Bou Grara (*Gighti*), Dougga (*Thugga*), Henchir Kasbat (*Thurburbo Maius*), Medeina (*Althiburus*), and Sbeitla (*Sufetula*); and Sabratha in Tripolitania. In all of these the usual public places are represented, the *forum* with its *curia*, *basilica*, and *rostra*, flanked by temples and porticoes which sheltered honorific statues. Khamissa has its table of standard measures still in place; Timgad, Lembaesis, Jemila and Henchir Kasbat have markets appropriately fitted for various commodities. In the military foundations these lie just outside the gates, but Timgad has also smaller and perhaps later markets within the ramparts. There is also a library at Timgad, unique in Africa. Baths and triumphal arches (gateways) abound on these and many other sites, and each city has its theatre; those of Cherchel and Dougga are particularly well preserved. The finest amphitheatre is at El Jem (*Thysdrus*). The official sacred building of a provincial town was the *capitolium*, and was usually placed near the *forum*, but at Timgad it lies outside the walls. The regular tripartite plan is seen in this example. At Dougga the front columns with their pediment are still standing, and at Sbeitla the capitol consists of three separate shrines. A temple at Tebessa (*Theveste*) is nearly intact, and has an elaborately carved parapet but no pediment. A notable temple is that of Aesculapius at Lembaesis, which has a thermal establishment attached and is approached through an avenue of subsidiary chapels. Many miles of aqueducts are standing between the cities and the springs from which they drew their water. The supply of Carthage came from Zaghouan, where there is an elaborate *Nymphaeum*. Similar water-sanctuaries exist at Hammam Derraji (*Bulla Regia*), Khamissa and elsewhere; the aqueduct at Sbeitla is carried over the ravine on a massive bridge. Houses of Graeco-Roman design like those of Pompeii have been excavated on many sites: most famous is the House of Sertius at Timgad, but this does not belong to the original city. Bulla Regia has some underground houses, and there are catacombs at Sousse (*Hadrumentum*).

Large quantities of Roman sculpture have been found in these excavations, and are housed in the local museums, among them many imperial portraits and other pieces of historical value. Inscriptions also are abundant. But the peculiar artistic riches of north Africa are mosaic pavements, which have for their subjects, besides decorative patterns, seascapes and landscapes, historical and mythological scenes, and incidents of agricultural life, fishing, hunting and games. Among them are portraits of Xenophon from Sbeitla and Virgil from Sousse. A large and varied series comes from a villa near Zliten in Tripolitania.

Vandal and Byzantine.—Mosaic decoration is a prominent feature in the remains of Early Christian churches (basilicas): there are particularly fine examples in the baptisteries of Jemila, Sbeitla and Timgad. At the last place the church is attached to a monastery, as also at Tebessa. Some of the churches are Late Roman, others are Byzantine foundations. During the short interval of Vandal occupation (A.D. 439–533) there seems to have been no architectural activity, but some fortification and a good deal of military demolition date from this epoch. Examples of the latter are supplied by the theatres of Carthage, which were filled in with the ruins of their superstructures. The great fortress walls that dominate many sites are Byzantine. They were erected to hold the civilized country against native tribes, the same aggressors that the Roman conquerors had to face; and it is

significant that the two most imposing Byzantine strongholds, at Haïdra and Tebessa, are on the sites of the first permanent camps that the Roman legion fortified on Mt. Aurea (*Ammaedara* and *Theveste*). Haïdra is the type of a military fort, Tebessa of a fortified city. The fortress-walls were made of ancient materials, and often incorporate whole buildings of preceding ages. Triumphal arches at Tebessa are worked into the circuit of the ramparts; one at Haïdra was built up to make a tower; the capitol of Dougga and Sbeitla were turned into forts. The ruin of classical buildings involved in these defensive works was immense, and it has been justly said that the real vandals of north Africa were the Byzantines. Arab conquests, though fatal to town-dwellers, did no great damage to the structures. Indeed their subsequent desertion and neglect have been the means of preserving so many Roman cities to an extent unequalled in any other land. (E. J. F.)

BIBLIOGRAPHY.—R. Cagnat, *Carthage, Timgad, Tébéssa et les Villes antiques de l'Afrique du Nord* (1909, a short illustrated survey). Detailed accounts of particular sites and monuments are mostly in series of monographs or periodicals published by the local Governments: S. Gsell, *Les Monuments antiques de l'Algérie* (1901, Service des Monuments Historiques); R. Cagnat and P. Gauckler, *Les Monuments historiques de la Tunisie* (1898, Direction des Antiquités et Arts); *Musées et Collections archéologiques de l'Algérie et de la Tunisie*; *Notiziario archeologico del Ministero delle Colonie and Africa Italiana* (from 1915, Cyrenaica and Tripolitania).

HISTORY

The ancient history of Africa is shrouded in mystery and the earliest records of that continent and its people are far from trustworthy. See AFRICA, ROMAN; EGYPT.

Phoenician and Greek Colonization.—The word Africa was applied originally to the country in the immediate neighbourhood of Carthage, that part of the continent first known to the Romans, and it was subsequently extended with their increasing knowledge. The Arabs still confine the name Ifrikia to the territory of Tunisia. If ancient Egypt and Ethiopia (*q.v.*) be excluded, the story of Africa is largely a record of the doings of its Asiatic and European conquerors and colonizers, Abyssinia being the only State which throughout historic times has maintained its independence. The countries bordering the Mediterranean were first exploited by the Phoenicians. Carthage, founded about 800 B.C., speedily grew into a city without rival in the Mediterranean, and the Phoenicians, subduing the Berber tribes, who then, as now, formed the bulk of the population, became masters of all the habitable region of north Africa west of the Great Syrtes. Both Egyptians and Carthaginians made attempts to reach the unknown parts of the continent by sea. The west coast was well known to the Phoenicians as far as Cape Nun, and c. 520 B.C. Hanno, a Carthaginian, explored the coast at least as far as Sierra Leone.

A WOMAN OF ZULULAND

Meantime the first European colonists had settled in Africa. Greeks founded the city of Cyrene (c. 631 B.C.) and exerted a powerful influence in Egypt. To Alexander the Great the city of Alexandria owes its foundation (332 B.C.), and under the Hellenistic dynasty of the Ptolemies attempts were made to penetrate southward, and in this way was obtained some knowledge of Abyssinia. Neither Cyrenaica nor Egypt was a serious rival to the Carthaginians, but all three Powers were eventually supplanted by the Romans after the fall of Carthage in 146 B.C. Under Rome the settled portions of the country were very prosperous, and a Latin strain was introduced into the land. Though Fezzan was occupied by them, the Romans elsewhere found the Sahara an impassable barrier. The utmost extent of geographical knowledge of the continent is shown in the writings of Ptolemy (2nd century A.D.), who guessed the existence of the great lake reservoirs of the Nile and had heard of the river Niger. (For the history of Africa under the empire, see ROMAN EMPIRE, LATER.)

The Arab Conquest.—In the 7th century an Arab host, following the new faith of Mohammed, conquered the whole country from the Red sea to the Atlantic and entered Spain. Throughout north Africa Christianity well-nigh disappeared, save in Egypt (where the Coptic Church was suffered to exist), and Upper Nubia and Abyssinia, which were not subdued. In the 8th, 9th and 10th centuries the Arabs in Africa were numerically weak; but in the

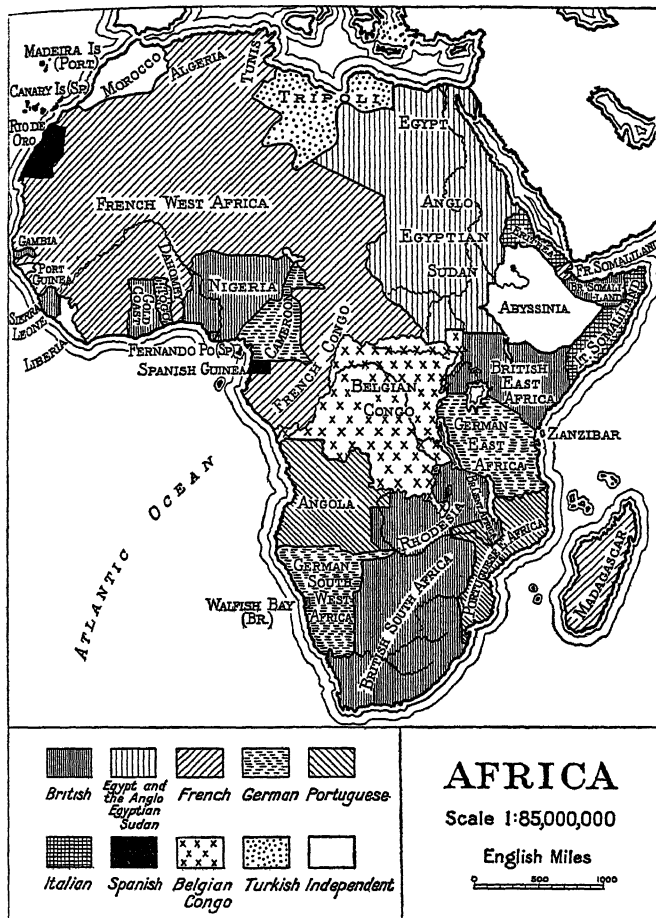

middle Niger regions fell under the influence of the Arabs and Berbers, but it was not until 1591 that Timbuktu—founded in the 11th century—became Muslim. That city had been reached in 1352 by the great Arab traveller Ibn Batuta, to whose journey to Mombasa and Quiloa (Kilwa) was due the first accurate knowledge of those flourishing Muslim cities on the east African sea-board. Except along this sea-board, which was colonized directly from Asia, Arab progress southward was stopped by the broad belt of dense forest which, stretching almost across the continent somewhat south of 10° N., barred their advance as effectually as had the Sahara that of their predecessors, and cut them off from knowledge of the Guinea coast and of all Africa beyond. One of the regions which came latest under Arab control was Nubia, where a Christian civilization and State existed up to the 14th century.

For a time the Muslim conquests in south Europe had virtually made of the Mediterranean an Arab lake, but in the 11th century the Norman conquest of Sicily was followed by their descent on Tunisia and Tripoli. Somewhat later a busy trade with the African coast-lands, especially Egypt, was developed by the cities of north Italy. The Italians also, in the 14th and 15th centuries, traded with the countries of the Niger bend and were conversant with the routes across the Sahara. Some Europeans even traversed the desert, while one traveller—not a merchant—the Frenchman Anselme d'Isalguier reached Gao on the Niger, in 1405.¹ Meanwhile events were impending which were to have a profound effect on north-west Africa. By the end of the 15th century Spain had completely thrown off the Muslim yoke, but even while the Moors were still in Granada, Portugal was strong enough to carry the war into Africa. In 1415 a Portuguese force captured the citadel of Ceuta on the Moorish coast. From that time Portugal repeatedly interfered in the affairs of Morocco, while Spain acquired many ports in Algeria and Tunisia. Portugal, however, suffered a crushing defeat in 1578 at al Kasr al Kebir, the Moors being led by Abd el Malek I. of the Sherifan dynasty. By that time the Spaniards had lost almost all their African possessions. The Barbary States degenerated into mere communities of pirates, and under Turkish influence civilization and commerce declined. (X.)

MODERN HISTORY

The Portuguese.—But with the battle of Ceuta, Africa had ceased to belong solely to the Mediterranean world. Among those who fought there was Prince Henry "the Navigator," son of King John I., who was fired with the ambition to acquire for Portugal the unknown parts of Africa. Under his inspiration and direction was begun that series of voyages of exploration which resulted in the circumnavigation of Africa and the establishment of Portuguese sovereignty over large areas of the coast-lands. Cape Bojador was doubled in 1434, Cape Verde in 1445, and by 1480 the whole Guinea coast was known. In 1482 Diogo Cam or Cão discovered the mouth of the Congo; the Cape of Good Hope was doubled by Bartholomew Diaz in 1488, and in 1498 Vasco da Gama, after having rounded the Cape, sailed up the east coast, touched at Sofala and Malindi, and went thence to India. Over all the countries discovered by their navigators Portugal claimed sovereign rights, but these were not exercised in the extreme south of the continent. The Guinea coast, as the first discovered and the nearest to Europe, was first exploited. Numerous forts and trading stations were established, the earliest being São Jorge da Mina (Elmina), begun in 1482. The chief commodities dealt in were slaves, gold, ivory and spices. The discovery of America (1492) was followed by a great development of the slave trade, which, before the Portuguese era, had been an overland trade almost exclusively confined to Mohammedan Africa. The lucrative nature of this trade, and the large quantities of alluvial gold obtained by the Portuguese, drew other nations to the Guinea coast. English mariners went thither as early as 1553, and they were followed by Spaniards, Dutch, French, Danish, and

¹D'Isalguier afterwards wrote an account (never published) of his travels, which were made known in 1927 by Charles de la Roncière in vol. iii. of *La Découverte de l'Afrique au Moyen Âge*.

POLITICAL DIVISIONS OF AFRICA IN 1910 AT THE CLOSE OF THE FINAL PHASE OF THE INTERNATIONAL "SCRAMBLE FOR TERRITORY"
Two further adjustments took place before the World War. By the 1911 agreement the Cameroon received two tongue-like extensions—one reaching to the Congo river, the other to the Ubangi. On Nov. 5, 1911, as the result of a brief war with Turkey, Italian sovereignty was extended over Tripoli

11th century there was a great Arab immigration. Even before this the Berbers had very generally adopted the speech and religion of their conquerors. Arab influence and the Mohammedan religion thus became indelibly stamped on northern Africa. Together they spread southward across the Sahara, and became firmly established along the eastern sea-board, where Arabs, Persians and Indians planted flourishing maritime and commercial colonies. Of these eastern cities and States both Europe and the Arabs of north Africa were long ignorant.

The first Arab invaders had recognized the authority of the caliphs of Baghdad. Early in the 10th century the Fatimite dynasty established itself in Egypt, where Cairo had been founded A.D. 968, and from there ruled as far west as the Atlantic. Later still arose other dynasties such as the Almoravides and Almohades. Eventually the Turks, who had seized Egypt in 1517, established the regencies of Algeria, Tunisia and Tripoli (between 1519 and 1551), Morocco remaining an independent Arabized Berber State under the Sharifan dynasty, which had its beginnings at the end of the 13th century. Under the earlier dynasties the spirit of adventure and the proselytizing zeal of the followers of Islam led to a considerable extension of the knowledge of the continent. This was rendered more easy by their use of the camel, which enabled the Arabs to traverse the desert. In this way Senegambia and the

other adventurers. Much of Senegambia was made known as a result of quests during the 16th century for the "hills of gold" in Bambuk and the fabled wealth of Timbuktu, but the middle Niger was not reached. The supremacy along the coast passed in the 17th century from Portugal to Holland and from Holland in the 18th and 19th centuries to France and England. The whole coast from Senegal to Lagos was dotted with forts and "factories" of rival Powers, and this international patchwork persists though all the *hinterland* has become either French or British territory.

Southward from the mouth of the Congo¹ to the inhospitable region of Damaraland, the Portuguese, from 1491 onward, acquired influence over the Bantu-Negro inhabitants, and in the early part of the 16th century through their efforts Christianity was largely adopted in the native kingdom of Congo. An irruption of cannibals from the interior later in the same century broke the power of this semi-Christian state, and the Portuguese activity was transferred to a great extent farther south, São Paulo de Loanda being founded in 1576. The sovereignty of Portugal over this coast region, except for the mouth of the Congo, has been only once challenged by a European Power, and that was in 1640-48, when the Dutch held the seaports.

Neglecting the comparatively poor and thinly inhabited regions of South Africa, the Portuguese no sooner discovered than they coveted the flourishing cities held by Arabized peoples between Sofala and Cape Guardafui. By 1520 all these Muslim sultanates had been seized by Portugal, Mozambique being chosen as the chief city of her East African possessions. Nor was Portuguese activity confined to the coast-lands. The lower and middle Zambezi valley was explored (16th and 17th centuries), and here the Portuguese found semi-civilized Bantu-Negro tribes, who had been for many years in contact with the coast Arabs. Strenuous efforts were made to obtain possession of the country (modern Rhodesia) known to them as the kingdom or empire of Monomotapa, where gold had been worked by the natives from about the 12th century A.D., and whence the Arabs, whom the Portuguese dispossessed, were still obtaining supplies in the 16th century. Several expeditions were despatched inland from 1569 onward and considerable quantities of gold were obtained. Portugal's hold on the interior, never very effective, weakened during the 17th century, and in the middle of the 18th century ceased with the abandonment of the forts in the Manica district.

At the period of her greatest power Portugal exercised a strong influence in Abyssinia also. In the ruler of Abyssinia (to whose dominions a Portuguese traveller had penetrated before Vasco da Gama's memorable voyage) the Portuguese imagined they had found the legendary Christian king, Prester John, and when the complete overthrow of the native dynasty and the Christian religion was imminent by the victories of Mohammedan invaders, the exploits of a band of 400 Portuguese under Christopher da Gama during 1541-43 turned the scale in favour of Abyssinia and had thus an enduring result on the future of north-east Africa. After da Gama's time Portuguese Jesuits resorted to Abyssinia. While they failed in their efforts to convert the Abyssinians to Roman Catholicism they acquired an extensive knowledge of the country. Pedro Paez in 1615, and, ten years later, Jeronimo Lobo, both visited the sources of the Blue Nile. In 1663 the Portuguese, who had outstayed their welcome, were expelled from the Abyssinian dominions. At this time Portuguese influence on the Zanzibar coast was waning before the power of the Arabs of Muscat, and by 1730 no point on the east coast north of Cape Delgado was held by Portugal.

The English and the Dutch.—It has been seen that Portugal took no steps to acquire the southern part of the continent. To the Portuguese the Cape of Good Hope was simply a landmark on the road to India, and mariners of other nations who followed in their wake used Table Bay only as a convenient spot wherein to refit on their voyage to the East. By the beginning of the 17th century the bay was much resorted to for this purpose,

chiefly by English and Dutch vessels. In 1620, with the object of forestalling the Dutch, two officers of the East India Company, on their own initiative, took possession of Table Bay in the name of King James, fearing otherwise that English ships would be "frustrated of watering but by licence." Their action was not approved in London, and the proclamation they issued remained without effect. The Netherlands profited by the apathy of the English. On the advice of sailors who had been shipwrecked in Table Bay the Netherlands East India Company, in 1651, sent out a fleet of three small vessels under Jan van Riebeeck which reached Table Bay on April 6, 1652, when, 164 years after its discovery, the first permanent white settlement was made in South Africa. The Portuguese, whose power in Africa was already waning, were not in a position to interfere with the Dutch plans, and England was content to seize the island of St. Helena as her half-way house to the East.¹ In its inception the settlement at the Cape was not intended to become an African colony, but was regarded as the most westerly outpost of the Dutch East Indies. Nevertheless, despite the paucity of ports and the absence of navigable rivers, the Dutch colonists, freed from any apprehension of European trouble by the friendship between Great Britain and Holland and leavened by Huguenot blood, gradually spread eastward.

MODERN EXPLORATION

During the 18th century there is little to record in the history of Africa. The nations of Europe, engaged in the later half of the century in almost constant warfare and struggling for supremacy in America and the East, to a large extent lost their interest in the continent. Only on the west coast was there keen rivalry, and here the motive was the securance of trade rather than territorial acquisitions. In this century the slave trade reached its highest development, the trade in gold, ivory, gum, and spices being small in comparison. In the interior of the continent—Portugal's energy being expended—no interest was shown, the nations with establishments on the coast "taking no further notice of the inhabitants or their land than to obtain at the easiest rate what they procure with as little trouble as possible, or to carry them off for slaves to their plantations in America" (*Encyclopædia Britannica*, 3rd. ed. 1797). Even the scanty knowledge acquired by the ancients and the Arabs was in the main forgotten or disbelieved. It was the period when—

Geographers, in Afric maps,
With savage pictures filled their gaps,
And o'er unhabitable downs
Placed elephants for want of towns.

(*Poetry, a Rhapsody*. By Jonathan Swift.)

The prevailing ignorance may be gauged by the statement in the third edition of the *Encyclopædia Britannica* that "the Gambia and Senegal rivers are only branches of the Niger." But the closing years of the 18th century, which witnessed the partial awakening of the public conscience of Europe to the iniquities of the slave trade, were also notable for the revival of interest in inner Africa. A society, the African Association,² was formed in London in 1788 for the exploration of the interior of the continent. The era of great discoveries had begun a little earlier in the famous journey (1770-72) of James Bruce through Abyssinia and Sennar, during which he determined the course of the Blue Nile. But it was through the agents of the African Association that knowledge was gained of the Niger regions. The Niger was reached by Mungo Park, who travelled by way of the Gambia, in 1795. Park, on a second journey in 1805, passed Timbuktu and descended the Niger to Bussa, where he lost his life, having just failed to solve the question as to where the river reached the ocean. (This problem was ultimately solved by Richard Lander and his brother in 1830.) The first scientific explorer of South-East Africa, Dr. Francisco de Lacerda, a Portu-

¹France acquired, as stations for her ships on the voyage to and from India, settlements in Madagascar and the neighbouring islands. The first settlement was made in 1642.

²The Association, in 1831, was merged in the Royal Geographical Society.

¹This river was called by the Portuguese the Zaire. They appear to have made no attempt to trace its course beyond the rapids which stop navigation from the sea.

guese, also lost his life in that country. Lacerda travelled up the Zambezi to Tete, going thence towards Lake Mweru, near which he died in 1798. The first recorded crossing of Africa was accomplished between the years 1802 and 1811 by two half-caste Portuguese traders, Pedro Baptista and A. José, who passed from Angola eastward to the Zambezi.

Although the Napoleonic wars distracted the attention of Europe from exploratory work in Africa, those wars nevertheless exercised great influence on the future of the continent, in both Egypt and South Africa. The occupation of Egypt (1798-1803) first by France and then by Great Britain, resulted in an effort by Turkey to regain direct control over that country,¹ followed in 1811 by the establishment, under Mohammed Ali, of an almost independent state, and the extension of Egyptian rule over the eastern Sudan (from 1820 onward). In South Africa the struggle with Napoleon caused Great Britain to take possession of the Dutch settlements at the Cape, and in 1814 Cape Colony, which had been continuously occupied by British troops since 1806, was formally ceded to the British crown.

The close of the European conflicts with the battle of Waterloo was followed by vigorous efforts on the part of the British Government to become better acquainted with Africa, and to substitute colonization and legitimate trade for the slave traffic, declared illegal for British subjects in 1807 and abolished by all other European Powers by 1836. To West Africa Britain devoted much attention. The slave trade abolitionists had already, in 1788, formed a settlement at Sierra Leone, on the Guinea coast, for freed slaves, and from this establishment grew the colony of Sierra Leone,² long notorious, by reason of its deadly climate, as "The White Man's Grave." Farther east the establishments on the Gold Coast began to take a part in the politics of the interior, and the first British mission to Kumasi, despatched in 1817, led to the assumption of a protectorate over the maritime tribes heretofore governed by the Ashanti.

An expedition sent in 1816 to explore the Congo from its mouth did not succeed in getting beyond the rapids which bar the way to the interior, but in the central Sudan much better results were obtained. In 1823 three English travellers, Walter Oudney, Dixon Denham, and Hugh Clapperton, reached Lake Chad from Tripoli—the first white men to reach that lake. The partial exploration of Bornu and the Hausa states by Clapperton, which followed, revealed the existence of large and flourishing cities and a semi-civilized people in a region hitherto unknown. The discovery in 1830 of the mouth of the Niger by Clapperton's servant, Lander, already mentioned, had been preceded by the journeys of Maj. A. G. Laing (1826) and René Caillié (1827) to Timbuktu, and was followed (1832-33) by the partial ascent of the Benue affluent of the Niger by MacGregor Laird. In 1841 a disastrous attempt was made to plant a white colony on the lower Niger, an expedition (largely philanthropic and anti-slavery in its inception) which ended in utter failure. Nevertheless, from that time British traders remained on the lower Niger, their continued presence leading ultimately to the acquisition of political rights over the delta and the Hausa states by Great Britain.³ Another endeavour by the British Government to open up commercial relations with the Niger countries resulted in the addition of a vast amount of information concerning the countries between Timbuktu and Lake Chad, owing to the labours of Heinrich Barth (1850-55), originally a subordinate, but the only surviving member of the expedition sent out.

Meantime considerable changes had been made in other parts of the continent, the most notable being the occupation of Algiers by France in 1830, an end being thereby put to the piratical proceedings of the Barbary States; the continued expansion southward of Egyptian authority, with the consequent additions to the knowledge of the Nile; and the establishment of independent states (Orange Free State and the Transvaal) by Dutch

¹The Mamelukes, whom the Turks had overthrown in the 16th century, had regained practically independent power.

³The first territorial acquisition made by Great Britain in this region was in 1851, when Lagos Island was annexed.

farmers (Boers) dissatisfied with British rule in Cape Colony. Natal, so named by Vasco da Gama, had been made a British colony (1843), the attempt of the Boers to acquire it being frustrated. The city of Zanzibar, on the island of that name, founded in 1832 by Seyyid Said of Muscat, rapidly attained importance, and Arabs began to penetrate to the great lakes of East Africa,¹ concerning which little more was known (and less believed) than in the time of Ptolemy. Accounts of a vast inland sea, and the discovery in 1848-49, by the missionaries Ludwig Krapf and J. Rebmann, of the snow-clad mountains of Kilimanjaro and Kenya, stimulated in Europe the desire for further knowledge.

Livingstone and Stanley.—At this period, the middle of the 19th century, Protestant missions were carrying on active propaganda on the Guinea coast, in South Africa, and in the Zanzibar dominions. Their work, largely beneficent, was being conducted in regions and among peoples little known, and in many instances missionaries turned explorers and became pioneers of trade and empire. One of the first to attempt to fill up the remaining blank spaces in the map was David Livingstone, who had been engaged since 1840 in missionary work north of the Orange. In 1849 Livingstone crossed the Kalahari desert from south to north and reached Lake Ngami, and between 1851 and 1856 he traversed the continent from west to east, making known the great waterways of the upper Zambezi. During these journeyings Livingstone discovered, Nov. 1855, the famous Victoria Falls, so named after the queen of Great Britain. In 1858-64 the lower Zambezi, Shiré, and Lake Nyasa were explored by Livingstone, Nyasa having been first reached by the confidential slave of Antonio da Silva Porto, a Portuguese trader established at Bihé in Angola, who crossed Africa during 1853-56 from Benguela to the mouth of the Rovuma. While Livingstone circumnavigated Nyasa, the more northerly lake, Tanganyika, had been visited (1858) by Richard Burton and J. H. Speke, and the last named had sighted Victoria Nyanza. Returning to East Africa with J. A. Grant, Speke reached, in 1862, the river which flowed from Victoria

STANLEY GREET'S LIVINGSTONE WITH "DR. LIVINGSTONE, I PRESUME" After a hazardous journey of 295 days Stanley, on Oct. 25, 1871, reached Ujiji, where he found Dr. Livingstone, sick, emaciated and depressed

Nyanza and, following it (in the main) down to Egypt, had the distinction of being the first man to read the riddle of the Nile. In 1864 another Nile explorer, Samuel Baker, discovered the Albert Nyanza, the chief western reservoir of the river. In 1866 Livingstone began his last great journey, in which he made known Lakes Mweru and Bangweulu and discovered the Lualaba (the upper part of the Congo), but died (1873) before he had been able to demonstrate its ultimate course, believing indeed that the Lualaba belonged to the Nile system. Livingstone's lonely death in the heart of Africa evoked a keener desire than ever to complete the work he left undone. H. M. Stanley, who had in 1871

¹As early as 1848 an Arab from Zanzibar journeying across the continent had arrived at Benguela.

succeeded in finding and succouring Livingstone, started again for Zanzibar in 1874, and in the most memorable of all exploring expeditions in Africa circumnavigated Victoria Nyanza and Tanganyika, and, striking farther inland to the Lualaba, followed that river down to the Atlantic ocean—reached in Aug. 1877—and proved it to be the Congo. In South Africa, Karl Mauch in 1871 discovered the ruins of the great Zimbabwe in Mashonaland; and in the following year F. C. Selous began his journeys over South Central Africa.

Explorers were active also in other parts of the continent. Southern Morocco, the Sahara, and the Sudan were traversed in many directions between 1860 and 1875 by Gerhard Rohlfs, Georg Schweinfurth and Gustav Nachtigal. These travellers not only added considerably to geographical knowledge, but obtained invaluable information concerning the people, languages, and natural history of the countries in which they sojourned.¹ Among the discoveries of Schweinfurth was one that confirmed the Greek legends of the existence beyond Egypt of a pygmy race. But the first discoverer of the dwarf races of Central Africa was Paul du Chaillu, who found them in the Ogowé district of the west coast in 1865, five years before Schweinfurth's first meeting with the pygmies; du Chaillu having previously, as the result of journeys in the Gabun country between 1855 and 1859, made popular in Europe the knowledge of the existence of the gorilla, perhaps the gigantic ape seen by Hanno the Carthaginian, and whose existence, up to the middle of the 19th century, was thought to be as legendary as that of the pygmies of Aristotle.

Stanley's great journey down the Congo in 1875-76 initiated a new era in African exploration, and since 1875 the map has been filled with authentic topographical details. Within their respective spheres of influence each Power undertook detailed surveys, and the most solid of the latest accessions to knowledge have resulted from the labours of hard-working colonial officials toiling individually in obscurity.

In 1877 an important expedition was sent out by the Portuguese Government under Serpa Pinto, Brito Capello, and Roberto Ivens for the exploration of the interior of Angola. The first named made his way by the head-streams of the Kubango to the upper Zambezi, which he descended to the Victoria Falls, proceeding thence to Pretoria and Durban. Capello and Ivens confined their attention to the south-west Congo basin, where they disproved the existence of Lake Aquilunda, which had figured on the maps of that region since the 16th century. In a later journey (1884-85) Capello and Ivens crossed the continent from Mossamedes to the mouth of the Zambezi, adding considerably to the knowledge of the borderlands between the upper Congo and the upper Zambezi. More important results were obtained by the German travellers, Paul Pogge and Hermann von Wissmann, who (1880-82) passed through previously unknown regions beyond Muata Yanvo's kingdom, and reached the upper Congo at Nyangwe, whence Wissmann made his way to the east coast. In 1884-85 a German expedition under Wissmann solved the most important geographical problem relating to the southern Congo basin by descending the Kasai, the largest southern tributary, which contrary to expectation, proved to unite with the Kwango and other streams before joining the main river. Further additions to the knowledge of the Congo tributaries were made at the same time by the Rev. George Grenfell, a Baptist missionary, who (accompanied in 1885 by K. von François) made several voyages in the steamer "Peace," especially up the great Ubangi, ultimately proved to be the lower course of the Welle, discovered in 1870 by Schweinfurth.

East Africa.—The first new journey of importance in East Africa was made (1878-80) on behalf of the British African Exploration committee by Joseph Thomson, who after the death of his leader, Keith Johnston, made his way from the coast to the north end of Nyasa, thence to Tanganyika, on both sides of which he broke new ground, sighting the north end of Lake Rukwa on the east. In 1882-84 the French naval lieutenant, Victor Giraud, proceeded by the north of Nyasa to Lake Bang-

weulu, of which he made the first fairly correct map. North of the Zanzibar-Tanganyika route a large area of new ground was opened in 1883-84 by Thomson, who traversed the whole length of the Masai country to Lake Baringo and Victoria Nyanza, shedding the first clear light on the great East African rift-valley and neighbouring highlands, including Mts. Kenya and Elgon. A great advance in the region between Victoria Nyanza and Abyssinia was made in 1887-89 by the Austrians, Count Samuel Teleki and Lieut. Ludwig von Höhnel, who discovered the large Basso Norok, now known as Lake Rudolf, till then only vaguely indicated on the map as Samburu. At this time Somaliland was being opened up by English and Italian travellers. In 1883 the brothers F. L. and W. D. James penetrated from Berbera to the Webi Shebeli; in 1892 Vittorio Bottego (afterwards murdered in the Abyssinian highlands) started from Berbera and reached the upper Juba, which he explored to its source. The first person to cross from the Gulf of Aden to the Indian Ocean was an American, A. Donaldson Smith, who in 1894-95 explored the head-streams of the Webi Shebeli and also explored the Omo, the feeder of Lake Rudolf.

In the region north-west of Victoria Nyanza the greatest additions to geographical knowledge were made by H. M. Stanley in his last expedition, undertaken for the relief of Emin Pasha. The expedition set out in 1887 by way of the Congo and made its way, encountering immense difficulties, through the great equatorial forest, the character and extent of which were thus for the first time brought to light. The return was made to the east coast and resulted in the discovery of the great snowy range of Ruwenzori or Runsoro, and the confirmation of the existence of a third Nile lake discharging its waters into the Albert Nyanza by the Semliki river.

North and West Africa.—Great activity was also displayed in completing the work of earlier explorers in North and West Africa. Morocco was in 1883-84 the scene of important explorations by de Foucauld, a Frenchman who, disguised as a Jew, crossed and re-crossed the Atlas and supplied the first trustworthy information as to the orography of many parts of the chain. In 1887-89 Louis Gustave Binger, a French officer, made a great journey through the countries enclosed in the Niger bend, and in 1890-92 Col. P. F. Monteil went from St. Louis to Say, on the Niger, thence through Sokoto to Bornu and Lake Chad, whence he crossed the Sahara to Tripoli. Meantime explorers had been busy in the region between Lake Chad, the Gulf of Guinea, and the Congo. The Sanga, one of the principal northern tributaries of the Congo, was reached from the north by Lieut. Louis Mizon, a French naval officer, who drew the first line of communication between the Benue and the Congo (1890-92). In 1890 Paul Crampel, who in the previous year had explored north of the Ogowé, undertook a great expedition from the Ubangi to the Shari, but was attacked and killed, with several of his companions, on the borders of the Bagirmi. Several other expeditions followed, and in 1896 Emile Gentil reached the Shari, launched a steamer on its waters and pushed on to Lake Chad. Early in 1900 Lake Chad was also reached by F. Foureau, a French traveller, who had already devoted 12 years to the exploration of the Sahara, and who on this occasion had crossed the desert from Algeria and had reached the lake *via* Air and Zinder.

Equatorial Africa.—The last ten years of the 19th century also witnessed many interesting expeditions in east Central Africa. In 1891 Emin Pasha, accompanied by Dr. F. Stuhlmann, made his way south of Victoria Nyanza to the western Nile lakes, visiting for the first time the southern and western shores of Albert Edward. Stuhlmann also ascended the Ruwenzori range to a height of over 13,000 feet. In the same year Dr. O. Baumann, who had already done good work in Usambara, near the coast, started on a more extended journey through the region of steppes between Kilimanjaro and Victoria Nyanza, afterwards exploring the head-streams of the Kagera, the ultimate sources of the Nile. In the steppe region referred to he discovered two new lakes, Manyara and Eiassi, occupying parts of the East African valley system. This region was again traversed in 1893-94 by Count von Götzen, who continued his route westwards to Lake

¹Another great traveller of this stamp was Wilhelm Junker, who spent the greater part of the period 1875-86 in the east central Sudan.

Kivu, north of Tanganyika, which, though heard of by Speke over 30 years before, had never yet been visited. He also reached for the first time the line of volcanic peaks north of Kivu, one of which he ascended, afterwards crossing the great equatorial forest by a new route to the Congo and the west coast. Valuable scientific work was done in 1893 by Dr. J. W. Gregory, who ascended Mt. Kenya to a height of 16,000 feet. In 1893-94 Scott Elliot reached Ruwenzori by way of Uganda, returning by Tanganyika and Nyasa, and in 1896 C. W. Hobley made the circuit of the great mountain Elgon, north-east of Victoria Nyanza. In 1890 Mt. Kenya was ascended to its summit by a party under H. J. Mackinder. The exploration of Mt. Kilimanjaro has been the special work of Dr. Hans Meyer, who first directed his attention to it in 1887. The region south of Abyssinia proper and north of Lake Rudolf, being largely the basin of the Sobat tributary of the Nile, was traversed by several explorers, among whom may be mentioned Capt. M. S. Wellby, who in 1898-99 explored the chain of small lakes in south-east Abyssinia, pushed on to Lake Rudolf, and thence traversed hitherto unknown country to the lower Sobat. Other valuable expeditions of exploration and surveying were conducted by Donaldson Smith (1899-1900), Maj. H. H. Austin (1899-1901), Maj. A. St. H. Gibbons (1895-96, 1898-1900), Commander B. Whitehouse (1904-06), Lieut. Boyd Alexander, Sir H. H. Johnston, Maj. Powell-Cotton, and the duke of Abruzzi.

The first journey through the whole length of the continent was accomplished in the last two years of the century when a young Englishman, E. S. Grogan, starting from Cape Town, reached the Mediterranean by way of the Zambezi, the central line of lakes and the Nile. Other travellers followed in Grogan's footsteps, among the first Maj. Gibbons.

Additions to topographical knowledge were made from about 1890 onwards by the international commissions which traced the frontiers of the protectorates of the European powers. The Anglo-French commission in 1903 traced the Nigerian frontier from the Niger to Lake Chad, and in 1903-04 the Anglo-German commission fixed the Cameroon boundary between Yola, on the Benue, and Lake Chad. In 1901-02 a German Congolese commission surveyed Lake Kivu and the volcanic region north of the lake, while the Anglo-German boundary commission of 1902-04 surveyed the valley of the lower Kagera and fixed the exact position of Albert Edward Nyanza.

At the same time administrative needs forced the governments concerned to take in hand the survey of the countries under their protection. Before the close of the first decade of the 20th century tolerably accurate maps had been made of the German colonies, of a considerable part of West Africa, the Algerian Sahara, and the Anglo-Egyptian Sudan, mainly by military officers.

PARTITION AMONG EUROPEAN POWERS

In the last quarter of the 19th century the map of Africa was transformed. After the discovery of the Congo the story of exploration takes second place; the continent becomes the theatre of European expansions. Lines of partition, drawn often through trackless wildernesses, marked out the possessions of Germany, France, Great Britain, and other Powers. Railways penetrated the interior, vast areas were opened up to civilized occupation, and from ancient Egypt to the Zambezi the continent was startled into new life.

Before 1875 the only European Powers with any considerable interest in Africa were Britain, Portugal, and France.

In North Africa the Turks had (in 1835) assumed direct control of Tripoli, while Morocco had fallen into a state of decay though retaining its independence. A remarkable change had taken place in Egypt, where the Khedive Ismail had introduced a somewhat fantastic imitation of European civilization. In addition Ismail had conquered Darfur, annexed Harar and the Somali ports on the Gulf of Aden, was extending his power southward to the equatorial lakes, and even contemplated reaching the Indian ocean. The Suez canal, opened in 1869, had a great influence on the future of Africa, as it again made Egypt the highway to the East, to the detriment of the Cape route.

In 1875 other European nations—with the occasional exception of Great Britain—were indifferent to Portugal's pretensions, and her estimate of her African empire as covering over 700,000sq.m. was not challenged. But the area under effective control of Portugal at that time did not exceed 40,000 sq. miles. Great Britain then held some 250,000sq.m., France about 170,000sq.m., and Spain 1,000sq. miles. The total area of Africa ruled by Europeans did not exceed 1,271,000sq.m.; roughly one-tenth of the continent.

Egypt and the Egyptian Sudan, Tunisia, and Tripoli were subject in differing ways to the overlordship of the sultan of Turkey, and with these may be ranked, in the scale of organized governments, the three principal independent states, Morocco, Abyssinia, and Zanzibar, as also the negro republic of Liberia. There remained, apart from the Sahara, roughly one-half of Africa, lying mostly within the tropics, inhabited by a multitude of tribes and peoples living under various forms of government and subject to frequent changes in respect of political organization. In the whole of this vast region the negro and Negro-Bantu races predominated, for the most part untouched by Mohammedanism or Christian influences. The larger States and Sultanates possessed neither the means nor the inclination to extend their influence beyond their own borders. The exploitation of Africa continued to be entirely the work of alien races.

Leopold II.—The causes which led to the partition of Africa are to be found in the economic and political state of western Europe at the time. Germany, strong and united as the result of the Franco-Prussian War of 1870, was seeking new outlets for her energies—new markets for her growing industries, and with the markets, colonies. For different reasons the war of 1870 was also the starting-point for France in the building up of a new colonial empire. In her endeavour to regain the position lost in that war France had to look beyond Europe. To the two causes mentioned must be added others. Great Britain and Portugal, when they found their interests threatened, bestirred themselves, while Italy also conceived it necessary to become an African Power. The struggle was not, however, precipitated by the action of any of the great Powers but by the ambitious projects of Leopold II., king of the Belgians, who, in Sept. 1876, took what may be described as the first definite step in the modern partition of the continent. He summoned to a conference at Brussels representatives of Great Britain, Belgium, France, Germany, Austria-Hungary, Italy, and Russia, to deliberate on the best methods to be adopted for the exploration and civilization of Africa, and the opening up of the interior of the continent to commerce and industry. The conference was entirely unofficial. The delegates who attended neither represented nor pledged their respective governments. Their deliberations lasted three days and resulted in the foundation of "The International African Association," with its headquarters at Brussels. It was further resolved to establish national committees in the various countries represented, which should collect funds and appoint delegates to the International Association. The central idea appears to have been to put the exploration and development of Africa upon an international footing. But it quickly became apparent that this was an unattainable ideal. The national committees were soon working independently of the International Association, and the association itself passed through a succession of stages until it became purely Belgian in character, and at last developed into the Congo Free State, under the personal sovereignty of King Leopold.

Stanley's journey down the Congo had stirred ambition in other capitals than Brussels. France had always taken a keen interest in West Africa, and in the years 1875 to 1878 Savorgnan de Brazza had carried out a successful exploration of the Ogowe river to the south of the Gabon. In Portugal, too, the discovery of the Congo, with its magnificent unbroken waterway of more than a thousand miles into the heart of the continent, served to revive the languid energies of the Portuguese, who promptly began to furbish up claims whose age was in inverse ratio to their validity. In Jan. 1879 Stanley left Europe as the accredited agent of King Leopold and the Congo committee. De Brazza returned to Africa at the beginning of 1880, and while Stanley,

on behalf of King Leopold, was making treaties and founding stations along the southern bank of the river, de Brazza and other French agents were equally busy on the northern bank.

The Scramble for Territory.—Although the Transvaal between the years 1877 and 1881 had become and ceased to be British, in other respects British territory had been extended in South Africa. And in 1883, in order that the trade route to the interior might be kept open for British expansion northward from the Cape Colony, negotiations for the settlement of the western border of the restored republic were opened in London. The border was defined in the Convention of London (Feb. 27, 1884), and at the same time the Bechuana peoples were taken under British protection. Subsequently, March 23, 1885, the Bechuanaland Protectorate was extended northwards to 22° S. latitude, and westward to 20° E. longitude. (See SOUTH AFRICA, TRANSVAAL, etc.) Before the convention was signed measures had been taken—without British opposition—at Berlin to establish German authority on the west coast between the Orange river and the Portuguese province of Angola; and on Sept. 8, 1884, the German Government intimated to the British Government “that the west coast of Africa from 26° S. latitude to Cape Frio, excepting Walvis Bay, had been placed under the protection of the German emperor.” In the same year, through the activities of Gustav Nachtigal, Togo and the Cameroon district were placed under German protection. Before either of these events had occurred Great Britain had become alive to the fact that she could no longer dally with the subject, if she desired to consolidate her possessions in West Africa. The British Government had again and again refused to accord native chiefs the protection they demanded. The Cameroon chiefs had several times asked for British protection, and always in vain. But at last it became apparent, even to the official mind, that rapid changes were being effected in Africa, and on May 16, 1884, Edward Hyde Hewett, British consul, received instructions to return to the west coast and to make arrangements for extending British protection over certain regions. He arrived too late to save either Togoland or Cameroon, in the latter case arriving five days after King Bell and the other chiefs on the river had signed treaties with Nachtigal. But the British consul was in time to secure the delta of the River Niger and the Oil rivers district, extending from Rio del Rey to the Lagos frontier, where for a long period British traders had held almost a monopoly of the trade.

Meanwhile the French Government was strenuously endeavouring to extend France's influence in West Africa, in the countries lying behind the coast-line. During the year 1884 no fewer than 42 treaties were concluded with native chiefs, an even larger number having been concluded in the previous twelve-month. In this fashion France was pushing on towards Timbuktu, in steady pursuance of the policy which resulted in surrounding all the old British possessions in West Africa with a continuous band of French territory. On the lower Niger, however, in 1877, Mr. Goldie Taubman (afterwards Sir George Taubman Goldie) conceived the idea of establishing a settled government. Through his efforts the various trading firms formed themselves in 1879 into the “United African Company,” and the foundations were laid of something like settled administration. An application was made to the British Government for a charter in 1881, and the capital of the company increased to a million sterling. Henceforth the company was known as the “National African Company,” and it was acknowledged that its object was not only to develop the trade of the lower Niger, but to extend its operations to the middle reaches of the river, and to open up direct relations with the great Fula empire of Sokoto and the smaller states associated with Sokoto under a somewhat loosely defined suzerainty.

In North and East Africa also events had moved since 1875. In 1881 France, with the consent of the Powers, undertook to reorganize the finances and administration of the meagre remains of the once splendid and powerful kingdom of Tunis. Two years later, with Lord Granville's circular despatch of Jan. 3, 1883, England's long and onerous tutelage of Egypt began. (See EGYPT.) In East Africa, north of the Portuguese possessions, where the sultan of Zanzibar was the most considerable native

potentate, Germany was secretly preparing the foundations of German East Africa. Italy, too, had obtained a footing on the African continent. The Rubattino Steamship Company as far back as 1870 had bought the port of Assab as a coaling station, but it was not until 1882 that it was declared an Italian colony. This was followed by the conclusion of a treaty with the sultan of Assab, chief of the Danakil, signed on March 15, 1883, and subsequently approved by the king of Shoa, whereby Italy obtained the cession of part of Abdis (Aussa) on the Red sea, Italy undertaking to protect with her fleet the Danakil littoral. One other event must be recorded. The king of the Belgians had been driven to the conclusion that, if his African enterprise was to obtain any measure of permanent success, its international status must be recognized; and negotiations for the purpose were opened with various governments.

The Berlin Conference 1884-85.—With these events there had grown up a general conviction that it would be desirable for the Powers interested in Africa to come to some agreement as to “the rules of the game,” and to define their respective interests as far as practicable. A treaty between Britain and Portugal, giving undue recognition to Portuguese territorial claims, which was signed by Lord Granville on Feb. 26, 1884, but not ratified in view of the protests it had evoked, brought this sentiment to a head; and it was agreed to hold an international conference on African affairs. The conference assembled at Berlin on Nov. 15, 1884, and after protracted deliberations the “General Act of the Berlin Conference” was signed by the representatives of all the Powers attending the conference, on Feb. 26, 1885. The Powers represented were Germany, Austria-Hungary, Belgium, Denmark, Spain, the United States, France, Great Britain, Italy, Holland, Portugal, Russia, Sweden and Norway, and Turkey. Ratifications were deposited by all the signatory Powers with the exception of the United States. The General Act dealt with six specific subjects: (1) Freedom of trade in the basin of the Congo, (2) the slave trade, (3) neutrality of territories in the basin of the Congo, (4) navigation of the Congo, (5) navigation of the Niger, and (6) rules for future occupation on the coasts of the African continent. For the present purpose, however, the results effected by the Berlin Act may be summed up as follows. The signatory Powers undertook that any fresh act of taking possession on any portion of the African coast must be notified by the Power taking possession, or assuming a protectorate to the other signatory Powers. It was further provided that any such occupation to be valid must be effective. It is also noteworthy that the first reference in an international act to the obligations attaching to “spheres of influence” is contained in the Berlin Act.

Before the General Act was signed the International Association of the Congo was recognized by all the signatory Powers, with the not very important exception of Turkey. Two months later, in April 1885, King Leopold, with the sanction of the Belgian legislature, formally assumed the headship of the new state; and on Aug. 1 in the same year his Majesty notified the powers that from that date the “Independent State of the Congo” declared that “it shall be perpetually neutral” in conformity with the provisions of the Berlin Act. Thus was finally constituted the Congo Free State, under the sovereignty of King Leopold, though the boundaries claimed for it at that time were considerably modified by subsequent agreements.

Partition Treaties.—In the 15 years that remained of the 19th century the work of partition was practically completed. The international agreements which determined in the main the limits of the possessions of the various powers are:—

I. The agreement of July 1, 1890, between Great Britain and Germany defining their spheres of influence in East, West, and South-west Africa. This agreement was the most comprehensive of all the “deals” in African territory, and included in return for the recognition of a British protectorate over Zanzibar the cession of Heligoland to Germany.

II. The Anglo-French declaration of Aug. 5, 1890, which recognized a French protectorate over Madagascar, French influence in the Sahara, and British influence between the Niger and Lake Chad.

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA

AFRICAN MAMMALS, BY PAUL BRANSOM

Upper panel: Antelopes. There are about 150 kinds of antelopes, some nine-tenths of which are found in Africa. In size they range from pygmy forms, as the dik-dik, only about a foot high, to oxlike species, as the eland, which attains a weight of 1,500 pounds. Left to right: Springbuck; Sable Antelope; Kudu; Beatrix Antelope; Eland; Dik-dik

Centre panel, top row, left to right: Giraffe, the tallest of living animals, sometimes 18 ft. high measured from its head to the ground; Hartbeest; Waterbuck; Grant Zebra; Roan Antelope (between zebras); Palla or Impala; White-bearded Gnu; White-tailed Gnu. Of these the hartbeest, waterbuck, palla and the gnus are forms of antelopes. Right centre: Cape

Buffalo, a powerful animal allied to the ox, dangerous when wounded. Lower row, left to right: Lion and lioness, the most powerful of African beasts of prey; Grey Jackal; Spotted Hyena

Lower panel, left to right: Hippopotamus, the largest aquatic hoofed mammal, sometimes reaching a weight of four tons; African Elephant, the largest land mammal, differing in appearance from the Asiatic elephant chiefly in its much larger ears; Pygmy Hippopotamus, about 2½ ft. high, native to Liberia; Black Rhinoceros, a fierce fighter when brought to bay; African Wart-hog, a grotesque kind of wild swine, taking its name from the presence of large warty protuberance on the face

III. The Anglo-Portuguese treaty of June 11, 1891, whereby the Portuguese possessions of the west and east coasts were separated by a broad belt of British territory, extending north to Lake Tanganyika.

IV. The Franco-German convention of March 15, 1894, by which the Central Sudan was left to France (this region by an Anglo-German agreement of Nov. 15, 1893, having been recognized as in the German sphere). By this convention France was able to effect a territorial junction of her possessions in North and West Africa with those in the Congo region.

V. Protocols of March 24 and April 15, 1891, for the demarcation of the Anglo-Italian spheres in East Africa.

VI. The Anglo-French convention of June 14, 1898, for the delimitation of the possessions of the two countries west of Lake Chad, with the supplementary declaration of March 21, 1899, whereby France recognized the upper Nile valley as in the British sphere of influence.

The Congo State.—The Congo Free State, which occupied, geographically, a central position, may serve as the starting-point for the story of the partition after the Berlin Conference. By his will, dated Aug. 2, 1889, King Leopold made Belgium formally heir to the sovereign rights of the Congo Free State. Proposals for Belgium to assume responsibility for its administration were made unsuccessfully in 1895 and 1901. Later, the agitation in Great Britain and America against the Congo system of government and the admissions of an official commission of enquiry concerning its maladministration strengthened the movement in favour of transfer, until in 1905 Leopold II. was forced to yield, and the annexation treaty was approved by the Belgian parliament. Thus the Congo state, after an existence of 24 years as an independent power, became a Belgian colony. (See CONGO, FREE STATE AND BELGIAN CONGO.)

French and British Rivalry.—After the capture of Khartum and the death of Gen. C. G. Gordon, the Sudan was abandoned to the dervishes. The Egyptian frontier was withdrawn to Wadi Halfa, and the vast provinces of Kordofan, Darfur, and the Bahr-el-Ghazal were given over to dervish tyranny and misrule. It was obvious that Egypt would sooner or later seek to recover her position in the Sudan, as the command of the upper Nile was recognized as essential to her continued prosperity. But the international position of the abandoned provinces was by no means clear. The British Government, by the Anglo-German agreement of July 1890, had secured the assent of Germany to the statement that the British sphere of influence in East Africa was bounded on the west by the Congo Free State and by "the western watershed of the basin of the upper Nile"; but this claim was not recognized either by France or by the Congo Free State. From her base on the Congo, France was busily engaged pushing forward along the northern tributaries of the great river. The desire of France to secure a footing in the upper Nile valley was partly due to her anxiety to extend a French zone across Africa, but it was also to a large extent attributable to the belief, widely entertained in France, that by establishing herself on the upper Nile France could regain the position in Egyptian affairs which she had sacrificed in 1882.

In June 1896 Capt. J. Marchand left France with secret instructions to lead an expedition into the Nile valley. On July 10, 1898, he reached Fashoda, having established a chain of posts *en route*, and here the French flag was at once raised, and a "treaty" made with the local chief. Meanwhile, in 1896, an Anglo-Egyptian army, under the direction of Sir Herbert (afterwards Lord) Kitchener, had advanced southwards for the reconquest of the Egyptian Sudan. On Sept. 2, 1898, Khartum was captured, and the khalifa's army dispersed. It was then that news

BY COURTESY OF NORTHERN BAPTIST CONVENTION

When a chief dies, selected members of his retinue are killed, and buried with him; the village is then abandoned

reached the Anglo-Egyptian commander, from native sources, that there were white men flying a strange flag at Fashoda. The sirdar at once proceeded in a steamer up Nile, and courteously but firmly requested Capt. Marchand to remove the French flag. On his refusal the Egyptian flag was raised close to the French flag, and the dispute was referred to Europe for adjustment between the British and French Governments. A critical situation ensued. Neither Government was inclined to give way, and for a time war seemed imminent. Happily Lord Salisbury was able to announce, on Nov. 4, that France was willing to recognize the British claims, and the incident was finally closed on March 21, 1899, when an Anglo-French declaration was signed, by the terms of which France withdrew from the Nile valley and accepted a boundary line which satisfied her earlier ambition by uniting the whole of her territories in North, West, and Central Africa into a homogeneous whole, while effectually preventing the realization of her dream of a transcontinental empire from west to east.

British and Portuguese Spheres Defined.—In the southern half of the continent, between the years 1885 and 1891, the Portuguese possessions on the west and east coasts were delimited, and Matabeleland and Mashonaland were occupied by the British South Africa Company. (See RHODESIA.) The relations between the British and Portuguese territories were determined by the treaty of June 11, 1891. Apart from defining the British and Portuguese spheres both south and north of the Zambezi, it contained many other provisions relating to trade and navigation, providing, *inter alia*, a maximum transit duty of 3% on imports and exports crossing Portuguese territories on the east coast to the British sphere, freedom of navigation of the Zambezi and Shiré for the ships of all nations, and stipulations as to the making of railways, roads, and telegraphs. Portugal was given both banks of the Zambezi to a point ten miles west of Zumbo—the farthest settlement of the Portuguese on the river. The boundary between the Portuguese sphere of influence on the west coast and the British sphere of influence north of the Zambezi was only vaguely indicated; but it was to be drawn in such a manner as to leave the Barotse country within the British sphere. Before the conclusion of the treaty the British Government had made certain arrangements for the administration of the large area north of the Zambezi reserved to British influence. On Feb. 1 Sir Harry Johnston was appointed imperial commissioner in Nyasaland, and a fortnight later the British South Africa Company intimated a desire to extend its operations north of the Zambezi. Negotiations followed, and the field of operations of the Chartered Company was, on April 2, 1891, extended so as to cover (with the exception of Nyasaland) the whole of the British sphere of influence north of the Zambezi (afterwards Northern Rhodesia). On May 14 a formal protectorate was declared over Nyasaland, including the Shiré highlands and a belt of territory extending along the whole of the western shore of Lake Nyasa. The name was changed in 1893 to that of the British Central Africa Protectorate, for which designation was substituted in 1907 the more appropriate title of Nyasaland Protectorate.

British and German Rivalry.—In July 1890, the British and German Governments came to an agreement upon the limits of their respective spheres of influence in various parts of Africa, and the boundaries of German South-West Africa were fixed in the position they now hold as those of the territory mandated to the Union of South Africa. These Powers were also the two great rivals on the east coast. Germany, on Dec. 30, 1886, and Great Britain, on June 11, 1891, formally recognized the Rovuma river as the northern boundary of the Portuguese sphere of influence on that coast; but it was to the north of that river, over the vast area of east or east central Africa in which the sultan of Zanzibar claimed to exercise suzerainty, that the struggle between the two rival powers was most acute. By an exchange of notes in Oct.-Nov. 1886, to which the sultan adhered on Dec. 4, 1886, the British and German Governments determined what territories were to be assigned to the sultanate of Zanzibar and agreed to a delimitation of their respective spheres of influence in East Africa. On Sept. 3, 1888, the British East Africa Association

received a charter from the British Government and became the Imperial British East Africa Company. Shortly afterwards the German colony of East Africa was founded. (See KENYA.)

Meanwhile, in the country to the west and north of the British sphere of influence a contest for Uganda had arisen between Karl Peters and the British East Africa Company. The contest was decided in favour of the latter by the Anglo-German Agreement of July 1, 1890. The provisions relating to East Africa were these:—In return for the cession of Heligoland, Lord Salisbury obtained from Germany the recognition of a British protectorate over the dominions of the sultan of Zanzibar, including the islands of Zanzibar and Pemba, but excluding the strip leased to Germany, which was subsequently ceded absolutely to Germany. Germany further agreed to withdraw the protectorate declared over Witu and the adjoining coast up to Kisumu in favour of Great Britain, and to recognize as within the British sphere of influence the vast area bounded, on the south, by the frontier line laid down in the agreement of 1886, which was to be extended along the first parallel of south latitude across Victoria Nyanza to the frontiers of the Congo Free State, on the west by the Congo Free State and the western watershed of the Nile, and on the north by a line commencing on the coast at the north bank of the mouth of the River Juba, then ascending that bank of the river until it reached the territory at that time regarded as reserved to the influence of Italy¹ in Gallaland and Abyssinia, when it followed the frontier of the Italian sphere to the confines of Egypt. To the south-west of the German sphere in East Africa the boundary was formed by the eastern and northern shore of Lake Nyasa, and round the western shore to the mouth of the Songwe river, from which point it crossed the Nyasa-Tanganyika plateau to the southern end of the last-named lake, leaving the Stevenson road on the British side of the boundary. The effect of this treaty was to remove all serious causes of dispute about territory between Germany and Great Britain in East Africa. It rendered quite valueless Peter's treaty with Mwanga and his promenade along the Tana; it freed Great Britain from any fear of German competition to the northwards, and recognized that her influence extended to the western limits of the Nile valley. But, on the other hand, Great Britain had to relinquish the ambition of connecting her sphere of influence in the Nile valley with her possessions in Central and South Africa. On this point Germany was quite obdurate; and an attempt subsequently made (May 1894) to secure this object by the lease of a strip of territory from the Congo Free State was frustrated by German opposition. (See UGANDA; KENYA, and TANGANYIKA.)

On March 31 the union jack was raised, and on May 29 a fresh treaty was concluded with King Mwanga placing his country under British protection. A formal protectorate was declared over Uganda proper on June 19, 1894, which was subsequently extended so as to include the countries westwards towards the Congo Free State, eastwards to the British East Africa protectorate and Abyssinia, and northwards to the Anglo-Egyptian Sudan. The British East Africa protectorate was constituted in June 1895, when the Imperial British East Africa Company relinquished all its rights in exchange for a money payment, and the administration was assumed by the imperial authorities. On April 1, 1902, the eastern province of the Uganda protectorate was transferred to the British East Africa protectorate, which thus secured control of the whole length of the so-called Uganda railway, and at the same time were successful in obtaining access to the Victoria Nyanza.

¹At this period negotiations between Great Britain and Italy had begun but were not concluded.

Italy.—Early in the 'eighties as already seen, Italy had obtained her first formal footing on the African coast at the Bay of Assab (Aussa) on the Red Sea. In 1885 the troubles in which Egypt found herself involved compelled the khedive and his advisers to loosen their hold on the Red Sea littoral, and, with the tacit approval of Great Britain, Italy took possession of Massawa and other ports on that coast. In May 1889 the Italians concluded with the negus Menelek the Treaty of Ucciali which, besides settling the frontiers between Abyssinia and the Italian sphere, contained the following article:—

XVII. His Majesty the King of Kings of Ethiopia consents to avail himself of the Italian Government for any negotiations which he may enter into with the other Powers or Governments.

In Italy and by other European governments this article was generally regarded as establishing an Italian protectorate over Abyssinia; but this interpretation was never accepted by the emperor Menelek, and at no time did Italy succeed in establishing any very effective control over Abyssinian affairs. By May 1894 under various agreements, the Italian and British Governments had fixed the northern limit of the Italian sphere as running from Ras Kasar on the Red Sea to the intersection of the Blue Nile with 35° E. longitude, and settled the boundary between their respective spheres on the Somali coast. But while Great Britain was thus lending her sanction to Italy's ambitious schemes the Abyssinian emperor was becoming more and more incensed at Italy's pretensions to exercise a protectorate over Ethiopia. In 1893 Menelek denounced the Treaty of Ucciali, and eventually, in a great battle, fought at Adowa on March 1, 1896, the Italians were disastrously defeated. By the subsequent Treaty of Addis Ababa, concluded on Oct. 26, 1896, the whole of the country to the south of the Mareb, Belesa, and Muna rivers was restored to Abyssinia, and Italy acknowledged the absolute independence of Abyssinia. By later negotiations with his European neighbours, the emperor Menelek secured boundaries on the south and west more favourable to Abyssinia than those assigned under the Anglo-Italian agreement. And Italian Somaliland, bordering on the south-eastern frontier of Abyssinia, became limited to a belt of territory with a depth inland from the Indian ocean of from 180 to 250 miles.

Anglo-French Rivalry in West Africa.—In West Africa the real struggle was between France and Great Britain, and France played the dominant part, the exhaustion of Portugal, the apathy of the British Government and the late appearance of Germany in the field all being elements that favoured the success of French policy. Two phases may be distinguished: the first dealing with the coast colonies, the second with the middle Niger and Lake Chad. On the coast France was wholly successful in her design of isolating all Great Britain's separate possessions in that region, and of securing for herself undisputed possession of the upper Niger and of the countries lying within the great bend of that river. At the date of the Berlin Conference the present colonies of Southern Nigeria and the Gold Coast constituted a single colony under the title of the Gold Coast colony, but on Jan. 13, 1886, the territory comprised under that title was erected into two separate colonies—Lagos and the Gold Coast (the name of the former being changed in Feb. 1906 to the colony of Southern Nigeria). In Aug. 1896, following the destruction of the Ashanti power and the deportation of King Prempeh, as a result of the second Ashanti campaign, a British protectorate was declared over the whole of the Ashanti territories and a resident was installed at Kumasi. But no northern limit had been fixed beyond the 9th parallel, and the countries to the north—Gurunsi (Grusi), Mossi and Gurma—were entered from all sides by rival British, French, and German expeditions. A few days before the meeting of the Berlin Conference Sir George Goldie had succeeded in buying up all the French interests on the lower Niger. The British company's influence had at that date been extended by treaties with the native chiefs up the main Niger stream to its junction with the Benue, and some distance along this latter river. But the great Fula states of the central Sudan were still outside European influence; and the German Government made efforts to secure a footing on the lower Niger until the fall of Prince Bis-

marck in March 1890. On the failure of the half-hearted attempt made later to establish relations with Gando from Togoland, Germany dropped out of the competition for the western Sudan and left the field to France and Great Britain. After its first great success the National African Company obtained a charter from the British Government, and on July 10, 1886, it became "The Royal Niger Company."

Notwithstanding her strenuous efforts, France, in her advance down the Niger from Senegal, did not succeed in reaching Sego on the upper Niger, a considerable distance above Timbuktu, until the winter of 1890-91, and the rapid advance of British influence up the river raised serious fears lest the Royal Niger Company should reach Timbuktu before France could forestall her. In 1892, however, after a troublesome war, France annexed some portion of Dahomey on the coast and declared a protectorate over the rest of the kingdom. Thus was removed the barrier which had up to that time prevented France pushing her way Nigerwards from her possessions on the Slave Coast, as well as from the upper Niger and the Ivory Coast. Henceforth her progress from all these directions was rapid, and in particular Timbuktu was occupied in the last days of 1893. It then appears to have been suddenly realized in France that, for the development of the vast regions which she was placing under her protection in West Africa, it was extremely desirable that she should obtain free access to the navigable portions of the Niger, if not on the left bank, from which she was excluded by the agreement of Aug. 5, 1890, then on the right bank, where the frontier had still to be fixed by international agreement. On Feb. 13, 1895, a French officer, Commander Toutée, arrived on the right bank of the Niger opposite Bajibo and built a fort. His presence there was notified to the Royal Niger Company, who protested to the British Government against this invasion of their territory; and eventually Toutée was ordered to withdraw, and the fort was occupied by the Royal Niger Company's troops. In 1897 the attempt was renewed in the most determined manner. In February of that year a French force suddenly occupied Bussa, and this act was quickly followed by the occupation of Gomba and Illo higher up the river. In Nov. 1897 Nikki was occupied. The situation on the Niger had so obviously been outgrowing the capacity of a chartered company that for some time before these occurrences the assumption of responsibility for the whole of the Niger region by the imperial authorities had been practically decided on; and early in 1898 Capt. F. D. (afterwards Lord) Lugard was sent out to the Niger with a number of imperial officers to raise a local force in preparation for the contemplated change. The advance of the French forces from the south and west was the signal for an advance of British troops from the Niger, from Lagos, and from the Gold Coast protectorate. The situation thus created was extremely serious. The British and French flags were flying in close proximity, in some cases in the same village. Meanwhile the diplomatists were busy in London and in Paris, and in the latter capital a commission sat for many months to adjust the conflicting claims. Fortunately, by the tact and forbearance of the officers on both sides, no local incident occurred to precipitate a collision, and on June 14, 1898, a convention was signed by Sir Edmund Monson and M. G. Hanotaux which practically completed the partition of this part of the continent. (See NIGERIA.)

Thus in its broad outlines the partition of Africa was begun and ended in the short space of a quarter of a century. The result was to divide the continent among the Powers as follows:—

	Square miles.
British Africa.....	2,101,411
Egyptian Africa.....	1,600,000
French Africa.....	3,866,950
German Africa.....	910,150
Italian Africa.....	200,000
Portuguese Africa.....	787,500
Spanish Africa.....	79,800
Belgian Africa.....	900,000
Turkish Africa.....	400,000
Independent Africa.....	613,000

11,458,811

Anglo-French Declaration, 1904.—There were still many finishing touches to be put to the structure, but a large contribution to the process was made by the Anglo-French declaration of April 8, 1904, when a series of agreements relating to several parts of the globe were signed in London by Lord Lansdowne, the foreign secretary, and M. Paul Cambon, the French ambassador, on behalf of their respective Governments. With regard to Egypt the French Government declared "that they [would] not obstruct the action of Great Britain in that country by asking that a limit of time be fixed for the British occupation or in any other manner." To understand the equivalent engagement taken by Britain, it must be recalled that to consolidate her position in north-west Africa France desired to make her influence supreme in Morocco. In April, 1902, it had been agreed between the French and Shereefian Governments to co-operate in establishing order in the frontier districts of Morocco and Algeria. Meanwhile in the northern districts of Morocco the unrest under the rule of the young sultan, Abd-el-Aziz IV., was attracting attention in Europe and evoking demands for its suppression. It was in these circumstances that in the declaration of April 1904 the British Government recognized "that it [appertained] to France, more particularly as a Power whose dominions [were] continuous for a great distance with those of Morocco, to preserve order in that country, and to provide assistance for the purpose of all administrative, economic, financial, and military reforms which it may require." Both parties, however, "inspired by their feeling of sincere friendship for Spain, [took] into special consideration the interests which that country [derived] from her geographical position and from her territorial possessions on the Moorish coast of the Mediterranean"; and in these interests the French Government undertook "to come to an understanding with the Spanish Government." The understanding was reached later in the same year, and thus Spain secured a sphere of interest on the Moroccan coast immediately facing the Spanish peninsula. Here it may be added that the protectorate of Spain over certain territories on the west coast of Africa, south of Morocco, had been notified to the Berlin Conference, and that by an agreement made with France in 1900 some 70,000sq.m. of the western Sahara were recognized as Spanish; while at the same time France admitted the claim of Spain to the ownership of the district around the Muni river to the south of Cameroons. The action taken by France in Morocco in accordance with the policy marked out in the Anglo-French declaration aroused the resentment of Germany, but on July 8, 1905, the republic secured from the German Government formal "recognition of the situation created for France in Morocco by the contiguity of a vast extent of territory of Algeria and the Shereefian empire, and by the special relations resulting therefrom between the two adjacent countries, as well as by the special interest for France, due to this fact, that order should reign in the Shereefian empire." Finally, in Jan.-April, 1906, a conference of the Powers was held at Algieras to devise, by invitation of the sultan, a scheme of reforms to be introduced into Morocco (*q.v.*). French capital was allotted a larger share than that of any other Power in the Moorish state bank which it was decided to institute, and French and Spanish officers were entrusted with the organization of a police force for the maintenance of order in the principal coast towns. The new régime had not been inaugurated fully, however, when a series of outrages led, in 1907, to the military occupation by France of Oudjda, a town near the Algerian frontier, and of the port of Casablanca on the Atlantic coast of Morocco.

LATER POLITICAL DEVELOPMENTS

The political map of Africa changed very considerably between 1910 and 1925. In 1910 the British self-governing colonies of the Cape, Natal, Transvaal, and Orange River were formed into the Union of South Africa, with a single government and one legislature. In 1911 a considerable area of French Equatorial Africa was transferred to German Cameroons and in return Germany acknowledged a French protectorate over the greater part of Morocco. On March 30, 1912, a protectorate treaty between France and the sultan was signed at Fez; and by a Franco-Span-

ish convention of Nov. 27 the Spanish zones in Morocco were defined. In 1912, also, Italy annexed the Turkish vilayets of Tripoli and Benghazi (Cyrenaica), to which the common name of Libya was given. In Dec. 1914 a British protectorate over Egypt was proclaimed, but by a declaration of Feb. 1922 Great Britain acknowledged the independence of Egypt. The status of the Anglo-Egyptian Sudan remained unchanged.

In June 1919, by the Treaty of Versailles, Germany renounced possession of all her overseas protectorates in favour of the principal Allied and Associated Powers. These territories, which had all been conquered by the Allies during the World War, were placed under mandates. The Union of South Africa became mandatory for German South-West Africa; Togoland was divided between France and Great Britain; and France became mandatory for Cameroons, except for a small portion which was placed under the administration of British Nigeria. Britain became mandatory for German East Africa, renamed the Tanganyika Territory, but by subsequent Anglo-Belgian agreements Belgium became mandatory for the provinces of Ruanda and Urundi. In 1920-25 Italy gained additions to Tripoli and Cyrenaica by arrangements with France and Egypt and to Italian Somaliland by arrangement with Great Britain.

As a result of these changes Africa was divided among the following Powers. The territories governed under mandate are reckoned in the possession of the Power named:—

France	4,200,000	Egypt	350,000
Great Britain	3,984,000*	Abyssinia	350,000
Belgium	930,000	Spain	140,000†
Portugal	788,000	Liberia	40,000
Italy	680,000		

*Including Anglo-Egyptian Sudan.

†Including the Spanish zones in Morocco.

These figures give a total of 11,462,000 sq.m. as the area of Africa. In the absence of definite surveys of large areas of the continent this may be regarded as a close approximation to accuracy.

German Policy.—The extinction of Turkish rule in North Africa had long been foreseen and was no matter for regret. It ended a connection which had lasted five centuries and had been almost wholly evil in its effects. German sovereignty in Africa had only dated from 1884 and had been rapidly enlarged. Endeavours to extend it further had been a prominent factor in German policy for a decade before the World War. Germany desired a footing on the African coast of the Mediterranean and a port on the Atlantic coast of Morocco. These desires conflicted with Italian and French ambitions, and in 1911 the issue on both points was decided against Germany. As to Morocco, a Franco-German convention of Feb. 9, 1909, had recognized the privileged position of France in Morocco, but not a French protectorate over that country, and the sending of the German gunboat, "Panther," to Agadir, in July, 1911, was a protest against what Germany considered an unwarranted extension of French influence in Morocco, and an intimation that if German treaty rights in Morocco were to be renounced, France must make compensation. The intervention of Great Britain on the side of France put an end to a dangerous situation; Germany, by a convention concluded Nov. 4, 1911, accepted compensation in Central Africa and withdrew opposition to the establishment of a French protectorate in Morocco.

While the Franco-German negotiations were in progress Italy abruptly declared war on Turkey and invaded, and held, Cyrenaica and Tripoli. Thus Germany, who had designed to exploit those vilayets through the medium of an Austro-Hungarian chartered

company, was deprived of her last opportunity—short of war—of gaining a foothold in the Mediterranean. She turned her attention to the development of a *Mittel Afrika* policy. This policy aimed at securing Germany's supremacy, primarily economic and ultimately political, in central equatorial Africa. The aim was to reserve the Belgian Congo, Angola and Mozambique, north of the Zambezi, as a German sphere, and thus to link up Cameroons with the South-West and East Africa protectorates. German industries had need of the raw material tropical Africa produces, and, moreover, southern Angola was a good field for European settlement.

British statesmen were not unfavourable to German expansion in equatorial Africa, so long as it was confined to the economic sphere. In 1898 an agreement, signed by Mr. A. J. (afterwards Lord) Balfour and Count Hatzfeldt, had divided Angola and Mozambique into spheres in which Great Britain and Germany respectively were to give financial and economic help to the Portuguese. This was followed in 1899 by the Treaty of Windsor, the object being to reassure Portugal that the Balfour-Hatzfeldt agreement was not in derogation of her sovereign rights in Africa. Neither the agreement with Germany nor the treaty with Portugal was published.

After the settlement of the Morocco crisis, Germany reopened negotiations with Great Britain in respect of Portugal's African colonies, and Prince Lichnowsky (the German ambassador) and Sir Edward (afterwards Lord) Grey reached a new agreement, which was ready for signature in 1913. Nearly all Angola was recognized as a German economic sphere, as well as the northern part of Mozambique. The rest of Mozambique, including Delagoa Bay and the Zambezi valley, was to be a British economic sphere. Sir Edward Grey made it a condition of signing that the 1898 and 1899 documents should be published. The German foreign office raised objections, Herr von Jagow (then foreign minister) stating that the German Press would regard the terms of the Treaty of Windsor and the Lichnowsky agreement as contradictory. In July 1914, however, German consent to publication had been given, but before the new agreement could be signed the World War had broken out.

The World War.—During the progress of the campaigns in Africa the whole of the continent, except Abyssinia and the Spanish protectorates, became involved in the struggle. The conquest of the German colonies was foreseen in the negotiation which preceded Italy's entry into the war, and Article 13 of the agreement signed in London on April 26, 1915, between France, Russia, Great Britain, and Italy, laid down that:—

In the event of France and Britain increasing their colonial territories in Africa at the expense of Germany, those two Powers agree in principle that Italy may claim some equitable compensation, particularly as regards the settlement in her favour of the questions relative to the frontiers of the Italian colonies of Eritrea, Somaliland and Libya, and the neighbouring colonies belonging to France and Great Britain.

Italian Ambitions.—Italian ambitions had gone beyond the readjustment of frontiers; in particular Italy wished to acquire Jibuti, the port of French Somaliland and the starting place of a railway to Abyssinia. As Jibuti was the only French port on the Suez canal route to the East and to Madagascar, as well as the only approach to Abyssinia that France possessed, she declined to entertain proposals for its surrender. Italy, however, obtained from France a welcome rectification of the Tripoli-Tunisia frontier, as well as valuable railway and commercial concessions in Tunisia.

In regard to the Cyrenaica-Egyptian frontier, the British Government, in 1919, offered Italy a readjustment of territory in the Libyan desert. The negotiations had not been concluded when Egypt was granted independence and after that time they were conducted directly between Italy and Egypt. They turned largely on the possession of the oasis of Jaghub, a place of some strategic importance, where is also the tomb-mosque of the founder of the Senussi sect. On Dec. 6, 1925, an Italo-Egyptian agreement was signed, by which Jaghub was included in Cyrenaica. The wells to the west of El Sollum were included in

HOW AFRICA'S 11 MILLION SQ.M. ARE DIVIDED AMONG THE NATIONS. THE STIPPLED PART IS THE 6.5 PER CENT OF THE CONTINENT OCCUPIED BY NATIVE STATES
S=Spain, 140,000 sq.m.
E=Egypt, 350,000 sq.m.
A=Abyssinia, 350,000 sq.m.
Small wedge=Liberia, 40,000 sq.m.

Egyptian territory, thus giving El Sollum a needed water supply. South of Siwa the frontier was drawn along longitude 25° E. to the boundary of the Anglo-Egyptian Sudan in latitude 22° North. The southern boundary of Libya—as the combined area of Tripolitania and Cyrenaica is named by the Italians—marches with French equatorial Africa and remains to be defined from Tummo eastwards. In 1925 the Anglo-Egyptian Sudan was verging on the position of a clearly defined British protectorate; the tributary sultanate of Darfur had been conquered in 1915; in 1922–23 the frontier separating it from French equatorial Africa, which had been in question since 1899, was delimited on the spot.

France and Spain.—In the same year (1912) that France obtained her protectorate in Morocco she concluded an arrangement with Spain whereby a Spanish protectorate was set up in the northern part of the sultanate, the port of Tangier and a small area around it being made, however, an international zone. In the French protectorate Marshal Lyautey, the resident-general, adopted a bold and conciliatory policy and won the confidence and respect of the Moors. He was succeeded in 1925 by M. Theodore Steeg, the governor-general of Algeria. In their zone the Spaniards met with determined opposition, largely owing to the uprising of a Moor, styled Abdel-Krim. In the territory known, somewhat vaguely, as Er-Rif, there seems to have been, as in the coastward portions of Algeria and Tunisia, a much more marked Iberian element in the population than there is in the south of Morocco, and this part of northern Morocco had shown a great hatred of European interference. The Spaniards suffered a severe reverse in 1921 and there was again heavy fighting in 1924 and 1925. In the last-named year the Rifs invaded the French zone, but were defeated and driven back. In the next year the insurrection was successfully quelled; and in 1927 the king and queen of Spain, when paying a ceremonial visit to the Spanish (northern) zone, were received cordially by the Moorish population.

Abyssinia under Ras Tafari made efforts to attain the position of a civilized power and joined the League of Nations Sept. 28, 1923. In the autumn of 1928 friction between the regent and the empress resulted in the exaltation of Ras Tafari to share the throne with the title of king. In Southern Rhodesia the growth of a vigorous white community led to that country being made, in 1923, a self-governing colony of the British empire, and with the assumption of direct imperial control of Northern Rhodesia in 1924 chartered-company rule in British Africa came to an end. In East Africa another vigorous and vocal white community made its influence felt, namely the settlers in the British East Africa Protectorate, which protectorate was annexed to the British Crown in 1920 and renamed Kenya Colony.

A subject which raised large issues was the position of Indians in South and East Africa, but it was of less importance than the growth of race consciousness among the Bantu and the negroes. Increase of education and of Christianity, the employment of large numbers of Africans in industries, and the lessons taught by the World War were among the factors which intensified the feeling of racial unity and led to manifestations of a new anti-white movement. This movement was different from the simple objection to interference by Europeans, or Arabs, previously displayed, and had a consciousness of the need of self-development and progress.

France in North Africa.—Apart from the awakening of the African peoples to race-consciousness, two recent developments in the European occupation of the continent are noticeable. France has shown definite progress in the task of restoring north-west Africa to the place in Mediterranean civilization which it held from the 6th century B.C. to the 7th century of the Christian era, when the Mohammedan conquest began. Under British administration the peoples of East Africa have emerged rapidly since the World War to industrial and political advancement. Since 1912, when she acquired the protectorate of Morocco, the authority of France has become increasingly effective in the fertile littoral and high plateaux of the western half of North Africa. The political and economic development of this Mediterranean area upon European lines has been assured by the expan-

sion of Algeria southward and the subsequent linking up of Saharan Algeria with the western Sudan, the French west coast colonies, and French Congo in a vast and coherent African empire. Barely a century ago the French expeditionary force landed at Sidi Ferruch on June 14, 1830. The declared purpose of the French cabinet was "to abolish slavery and piracy, to re-establish the security of navigation in the Mediterranean and open up its southern coasts anew to agriculture, civilization, commerce, and the free access of all nations." In the interval the "restricted occupation" of the coast towns has become the "total occupation" of Algeria, and the conquest of "the South"; while the incorporation of Northern Algeria into France has been followed by the protectorates of Tunis (1881) and Morocco (1912). Within these hundred years the European element in North Africa has risen from a handful of consular officials and merchants to well over a million residents, or approximately to one-tenth of the total population. Great European towns have been built. Agriculture and stock-raising have become infinitely more productive, minerals have been found and worked and new industries introduced. Order and public security have been established in regions to which Rome never sought to penetrate and over peoples that the legionaries strove in vain to subdue. The increasing throng of tourists who yearly traverse North Africa by rail and car from Algiers to the Saharan oases and from Carthage to Marrakesh, and the frequency and regularity of the steamship services which maintain intercourse between the European and African shores of the Mediterranean, are evidence of the success with which France has fulfilled her primary task of re-opening to Europe this lost province of the Graeco-Roman world.

British Development.—After the World War appreciable progress was made in the construction of development works and in production in Uganda, Kenya, and Tanganyika (formerly German East Africa); and with a view of increasing further the economic capacity of these and the neighbouring territories of Zanzibar, Nyasaland, and Northern Rhodesia, the possibility of administrative co-operation between the several governments concerned came under consideration. As the result of conferences on this subject held in 1927 the colonial office appointed the Hilton Young Commission to inquire into the question of the federation, or other union, of the British territories from Northern Rhodesia to Uganda. And, by the desire of its ministry, Southern Rhodesia (which became self-governing in 1923) was included in the scope of the commission. The project of an administrative union, of which this official enquiry into the views of the several governments and populations concerned was the first step, acquires a special interest from the character and geographical position of the colonies affected. Both the East, and the South African colonies are mixed African and European states, in which, although the mass of the inhabitants are African, the European minority is politically dominant. But while, broadly speaking, in the former the numerical predominance and economic importance of the African population are such that the interests of this population have priority in the eyes of the administration over those of the European, in the latter, with the exception of the native territories of the high commission, the European population and its economic importance are so relatively great that European interests stand first. In the East Coast colonies, however, African interests are not so predominant as they are in the (British) West Coast colonies; and in this respect these East Coast colonies hold a position midway between the frankly African West Coast colonies and the frankly European Union of South Africa and Southern Rhodesia. The federation, if effected, of a group of colonies of this intermediate type, by showing whether a central administration is a more effective medium for arriving at a due balance between African and European interests, may be expected to provide data germane to the whole subject of the European tutelage of African peoples. And in particular, as the result of the inclusion of Southern Rhodesia in the purview of the commission and the consequent possibility of Northern Rhodesia or its western portion being incorporated into Southern Rhodesia, it is probable that the question whether Northern Rhodesia, with its large area of 300,000 sq. m., is to be

administered as a "plantation" colony or to become a new centre of British population will be at length determined.

Tangier.—The status of the Tangier International Zone was regulated by the Act of Algieras (April 7, 1906), until modified by the conference which formulated the Tangier Statute in 1923. Although certain Powers signatory of the Algieras Act, notably Italy, withheld their adhesion, this protocol came into force on June 1, 1925. But Spain continued to maintain that the only satisfactory arrangement was the incorporation of Tangier in the Spanish Zone by which it was encircled: while France insisted that her position in Morocco required that Tangier and its communications should be under her control. The visit of a division of the Italian navy to Tangier in Oct. 1927, emphasized Italy's refusal to recognize the statute. On March 3, 1928, agreement was reached between France and Spain. At a second conference (March 20) of France, Spain, Italy and Great Britain the Franco-Spanish Agreement of March 3, was adopted, the statute was modified, and the claims of Italy to participate in the government of Tangier were satisfied (July 17).

RECENT EXPLORATION

Progress Since 1910.—The largest unknown area of Africa in 1910 was in the Sahara desert; the greatest gaps on the map were in the Libyan desert. In 1920-21 Miss Rosita Forbes took an expedition across the Libyan Desert to Kufra, the headquar-

A ZULU WARRIOR IN FULL BATTLE ARRAY

Carefully trained in military tactics, the Zulu warrior was feared by his neighbours as a formidable enemy

ters of the Senussi Tariq. In 1922-23 Ahmed Bey Hassanein, who had accompanied her, led an expedition through Kufra and the southern oases to Darfur. Miss Forbes has made further journeys through Abyssinia, the western Mauretanian desert and western Arabia. Hassanein Bey in 1923 journeyed through the Libyan desert into Darfur and Kordofan. Previous explorations by the French (1912-17) had increased knowledge of the eastern limits of the Chad basin, and had definitely proved its distinction from the western basin of the Nile. Col. Tilho's expeditions had revealed altitudes in Tibesti of 11,200ft. and the height of Mt. Tusi as 10,700ft.; lesser altitudes of 9,800ft. were determined at Jebel Marra, in Darfur, and of 4,000 to 5,000ft. on the western borders of the Sudan. The Tibesti belt of highland probably played a great part in southward spreads of fauna and flora in Miocene and Pliocene times. In the Nilotic Sudan, east of the main Nile, altitudes of 10,000ft. were discovered in 1911-12 by Col. H. D. Pearson. In 1916 Maj. Cuthbert Christy made an interesting journey along the south-western limits of the Nile basin, traversing the ironstone region where adjoining head-streams flow either southwards into the Mbomu and its affluents (Congo basin) or north-east into the Nile basin.

French officers, notably Capt. Augiéras, have conducted (from 1904) a scientific survey of the western Sahara, from southern Morocco to the Senegal river and the northern Niger. Augiéras has shown how the intense "desert" conditions of the western Sahara with few oases except on the periphery, accompany the extreme temperatures of the low-lying dunes, which quickly lose heat. The great Juf depression remained unexplored up to 1922; but since then the Citroën expedition from the latitudes of Insalah and Ahaggar in southern Algeria has increased our knowledge of this area. Portuguese Guinea, with its large rivers, has been partly explored, and since 1921 the vast southern part of the Niger basin, and the Black and White branches of the mighty Volta river, have become better known. Northern Togoland, Dahomey, southern Nigeria and the basin of the great Benue river have been mapped in detail.

East and Central Africa.—Much intensive work has been done in East and Central Africa. I. N. Dracopoli in 1912-1913 explored part of Jubaland; he reached the Lorian swamp, which receives the waters of the Uaso Nyiro, and showed its connection with the Juba river in Italian Somaliland. In April 1912 G. F. Archer (later Sir) completed surveys connecting the triangulation of British East Africa with the Abyssinian boundary survey. A survey by Capt. E. M. Jack, in 1911, of the region between Lakes Kivu and Victoria added to the knowledge of the Mufumbiro range of active volcanoes; Karisimbi was found to be 14,780ft. high. Since that time the Mufumbiro region and western Uganda have been surveyed in considerable detail. In 1927 geologists of the Swedish Institute found three series of sloping beaches along

the Rift valley between Menengai and Longonot, and also collected much data relative to the glaciation of Mt. Elgon and Kilimanjaro, and to the glacial geology of East Africa in general.

The first survey along its whole length of the Congo-Zambezi watershed was made in 1911-14 by Anglo-Belgian and Anglo-Portuguese boundary commissions. Many rivers run for considerable distances parallel to the divide, which is largely bush-covered. Maj. Reginald Walker, one of the British commissioners, discovered that the Luapula, a main headstream of the Congo, did not issue from Lake Bangweulu, but was a continuation of the Chambezi, which passes through the great swamp south of Bangweulu.

Results of the War.—During the World War, needs of campaigning led to many additions to the knowledge of the topography of inter-tropical Africa, partly through use of aircraft for survey purposes. Thus very useful maps were made of the northern part of Portuguese East Africa. In 1920 Dr. P. Chalmers Mitchell, who flew over the Nile basin proved the value of air reconnaissance to geology by the discovery in the Bayuda desert, north of Khartoum, of the volcanic character of a range of hills. A little later the French began to use aeroplanes for survey purposes in the Sahara. (X.)

AFRICA, ROMAN, comprised the whole of the continent known to the ancients, except Egypt and Ethiopia. The official and administrative language used the word Africa in a narrow sense, as noticed below. The term was borrowed by the Romans from the language of the natives. In Latin literature it was employed for the first time by the poet Ennius, who used it of the territory of Carthage and the eastern group of the Atlas. Numerous conjectures have been made as to the etymology of the term Africa; the best is that of Charles Tissot, who sees in the word "Africa" the name of the great Berber tribe, the Aourigha (whose name would have been pronounced Afarika), the modern Aouraghen, in ancient times the principal indigenous element of the African empire of Carthage (Tissot, *Géogr. comp.* i. 389). Africa was, in the eyes of the Romans and Carthaginians alike, the country inhabited by the great tribe of Berbers or Numidians called Afarik.

At the time of the Third Punic War the Africa of the Carthaginians was but a fragment of their ancient native empire, the rest of Africa having passed into the hands of the kings of Numidia, who were allies of the Romans.

After the capture of Carthage by Scipio (146 B.C.) this territory became a Roman province, and a trench, the *fossa regia*, was dug to mark the boundary of the Roman province of Africa and the dominions of the Numidian princes. The remains of this ditch, protected by a low wall or a stone dyke, have been discovered (1907); some of the boundary stones which marked its course, and inscriptions mentioning it, have also been found. From Testur on the Mejerda the *fossa regia* can be followed by these indications for several miles along the Jebel esh-Sheid. The ditch ran northward to Tabarca and southward to Tina. The ditch which in later times divided the provinces of *Africa vetus* and *Africa nova* was at the time of the Third Punic War the boundary of Carthaginian territory. The government of the Roman province thus delimited was entrusted to a *praetor* or *propraetor*. The towns which had fought on the side of the Romans during the Third Punic War were declared *civitates liberae*, and became exceedingly prosperous, e.g., Utica, Hadrumetum and Thapsus.

After the Jugurthine war in 106 B.C. the whole of the *regio Tripolitana* on the littoral of the two Syrtes, was annexed to the Roman province. The battle of Thapsus in 46 B.C. made the Romans definitely masters of Numidia which was converted into a new province called "*Africa Nova*": the old province of Africa was known as "*Africa Vetus*."

In 31 B.C. Octavius gave up Numidia, or Africa Nova, to King Juba II. Five years later Augustus gave Mauretania and some Gaetulian districts to Juba, and received in exchange Numidia, which thus reverted to direct Roman control, no longer forming a distinct government, but attached to the old province of Africa. From 25 B.C. the Roman province of Africa comprised

the region between the mouth of the Ampsaga (Wad Rummel, Wad el Kebir) on the west, and the two tumuli called the altars of the Philaeni, the immutable boundary between Tripolitana and Cyrenaica, on the east (Tissot ii. 261). In the partition of the government of the provinces of the Roman empire between the senate and the emperor, Africa fell to the senate, and was henceforth administered by a proconsul.

The province of Africa was the only senatorial province whose governor was originally invested with military powers. The proconsul of Africa had command of the *legio III. Augusta* and the auxiliary corps. But in A.D. 37 Caligula deprived the proconsul of his military powers and gave them to the imperial legate (*legatus Augusti pro praetore provinciae Africae*), whose special duty it was to guard the frontier zone (Tacitus, *Hist.* iv. 48; Dio Cass. lix. 20). The headquarters of the imperial legate were originally at Cirta and afterwards at Lambaesa (Lambessa). The military posts along the frontier of the desert formed an immense arc extending from Cyrenaica to Mauretania. A network of military routes, constructed and kept in repair by the soldiers, led from Lambaesa in all directions, and stretched along the frontier as far as Leptis Magna. The powers of the proconsul scarcely extended beyond the ancient *Africa Vetus* and the towns on the littoral. Septimius Severus detached from the province of Africa the greater part of Numidia to constitute a special province governed by a *procurator*, subordinate to the imperial legate and resident at Cirta (Tissot ii. 34). This province was called Numidia Cirtensis.

In Diocletian's reform, the whole of Roman Africa, with the exception of Mauretania Tingitana (which was attached to the province of Spain), constituted a single diocese subdivided into six provinces. Changes were necessitated by the wars with the Moors and the Vandals. By a treaty concluded in A.D. 476, the Emperor Zeno recognized Genseric as master of all Africa. Reconquered by Belisarius in 534, Africa formed, under the name of *praefectura Africae*, one of the great administrative districts of the Byzantine empire. In A.D. 647 the Arabs penetrated into *Ifrikia*, which was destined to fall for ever out of the grasp of the Romans. In A.D. 697 Carthage was taken.

The population of Roman Africa was composed of three chief elements: the indigenous Berber tribes, the ancient Carthaginians of Phoenician origin and the Roman colonists. The Berber tribes, whose racial unity is attested by their common spoken language and by the Berber inscriptions that have come down to us, bore in ancient times the generic names of Numidians, Gaetulians and Moors or Maurusiani. Besides the Afri (Aourigha) of the territory of Carthage, the principal tribes that took part in the wars against the Romans were the Lotophagi, the Garamantes, the Misulani or Musulamii, the Massyli and the Massaesyli. African epigraphy has revealed the names of some of their deities: *deus invictus Aulisva*; the god Motmanius, associated with Mercury; the god Lilleus; *Kautus pater*; the goddess Gilva, identified with Tellus (Tissot i. 486). There were also local divinities in all the principal districts. The rock bas-reliefs and other monuments showing native divinities are rare, and give only very summary representations.

During the Roman period the ancient Carthaginians of Phoenician origin and the bastard population termed by ancient authors Libyo-Phoenicians, formed the predominant populations of the towns on the littoral, and retained the Punic language until the 6th century of the Christian era. The municipal magistrates took the title of *suffetes* in place of that of *duumvirs*, and in certain towns the Christian bishops were obliged to know the *lingua Punica*, since it was the only language that the people understood. Nevertheless, the Roman functionaries, the army and the colonists from Italy soon brought the Latin element into Africa, where it flourished with such vigour that, in the 3rd century A.D., Carthage became the centre of a Romano-African civilization of extraordinary literary brilliancy, which numbered among its leaders such men as Apuleius, Tertullian, Arnobius, Cyprian and Augustine.

Carthage regained its rank of capital of Africa under Augustus, when thousands of Roman colonists flocked to the town. Utica

became a Roman colony under Hadrian, and the *civitates liberae*, *municipia*, *castella*, *pagi* and *turres* were peopled with Latins. The towns of the ancient province of Africa which received *coloniae* were very numerous.

The province of Numidia was at first colonized principally by the military settlements of the Romans. Cirta (Constantine) and Bulla Regia (Hammam Darraj), its chief towns, received *coloniae* of soldiers and veterans, as well as Theveste (Tebessa) and Thamugas (Timgad). The fine ruins which have been discovered at the last-mentioned place have earned for it the surname of the African Pompeii.

AFRICAN LANGUAGES. Language and race have not necessarily common boundaries, but in classifying a group of languages the relation between the two must not be ignored. Apart from recent European immigration, Africa has four main types of people: Pygmy-Bushman, Negro, Hamitic and Semitic. These four races correspond to four types of languages, though the Negro group was later subdivided into two different units, viz., Sudanic and Bantu.

There is a certain unanimity regarding the main divisions, and the five groups: Bushman, Sudanic, Bantu, Hamitic, Semitic, may be considered as finally settled. Problems on which no agreement has been arrived at are: the position of Bushman (and Pygmy), the unity of the Sudanic languages, the relation between Sudanic and Bantu, and the comprehension of the term Hamitic languages.

Semitic Languages.—These tongues are spoken in Abyssinia, probably as a result of colonization from southern Arabia. Ge'ez is extinct, Amharic (*q.v.*) is in part a modern representative of Ge'ez. Out of Amharic two new languages have evolved: Tigre and Tigrinya. Other dialects are those of Gurague and Harar. Of greater importance is Arabic, which is the ruling language in north Africa and in parts of eastern Sudan; through Islamic influence it has become a literary idiom in east Africa and the Sudan.

Bushman Languages.—The Bushman tribes speak a number of languages, which, however, are all allied and may be divided into three groups, southern, central and northern. Phonetically they are remarkable for the occurrence of the so-called clicks (*q.v.*). Another feature, not only in Bushman languages, but also in Hottentot, Sudanic and Bantu, is intonation (*see* TONES). Each syllable, and sometimes also a single-voiced consonant, has its own level of tone, which is as essential a part of a word as the sounds. Words with identical sounds, but differing in tone, have no etymological relation whatever to each other.

A number of the features of the Bushman languages are found in Sudanic languages, *e.g.*, intonation, monosyllabism, non-distinction between verb and noun in form, position of the genitive, formation of plural by "they," but as no etymological relations have as yet been ascertained it seems premature to ally the Bushman languages with the Sudanic group.

No Pygmy language is known. The Pygmies use their neighbours' speech. There seems to be evidence that some groups use a different mode of speech—yet unrecorded—in internal life.

Sudanic Languages.—This group is found, roughly speaking, in the stretch of the continent situated between the Atlantic ocean (Senegambia-Camerouns) and the western slopes of Abyssinia. Some enclaves, as Nuba and Kunama in the north, Gaya and Nyifwa-Kavirondo in east Africa, lie beyond this region.

This large group, stretching through the whole breadth of the continent, does not form a unit in the same sense as do the Bantu languages. It is broken up into numerous subdivisions, each of which has evolved its own type, and in the case of some tongues the divergences are so great that up to the present time, their relationship with others has not been demonstrated. The Sudan has been invaded over its whole area from time immemorial by peoples and languages from north and east. Linguistic conditions to-day are the result of this constant movement and shifting, which modified or destroyed original units and created new ones. Languages, probably whole groups of languages, have perished, or scanty remains have been embodied in new formations. As the invading tongues were largely of types differing radically from the Sudanic, these changes were radical and deeply influenced the original character of the language. Thus languages like Kanuri,

Wolof and others, have been so transformed that as yet their inclusion in the Sudanic group may seem to be merely theoretical.

Common Substratum.—While it is thus necessary to emphasize the highly complicated linguistic situation in the Sudan, and the present incomplete exploration of many problems involved, yet the Sudanic group as a whole shows certain common characteristics in phonology and structure, and there are also etymological relationships. There exists a common substratum of Sudanic speech, which is strongest where the original Negro element is strongest in population. This common substratum justifies the use of the term Sudanic languages. Some illustrations may be given: (1) the prevalence of intonation. (2) Monosyllabic stems (Ewe *ku* "death," Nuba *tu* "belly"). (3) Nouns are formed from verbs by a vocalic or nasal prefix (Yoruba *ra* "to buy," *o-ra* "buyer," Shilluk *bugo* "to press the bellows," *o-buk* "bellows"). (4) Plural of nouns is formed by adding to the noun a plural noun or pronoun (Ewe *ati* "tree," *ati-wo* "trees," Nuer *chak* "tick," *ke-chak* "ticks," *-wo* and *ke-* are the pronouns of the third person plural in Ewe and Nuer). (5) Plural of nouns is formed by adding *i* or *a* (Ibo *o-ru* "slave," *i-ru* "slaves"; Nuer *bel* "artist," *bel-i* "artists"; Edo *o-ya*, pl. *a-ya* "man"; Zande *boro*, pl. *a-boro* "man"). (6) Distinction between inanimate things and animate beings (or persons), the latter in most cases having the affix "*o*" (Twi *o-nipa* "man"; in Shilluk *o* designates persons as descendants of other persons: *nayo* "the mother's brother," *o-nayo* "the mother's brother's child"). There is no grammatical sex-distinction. (7) In genitive relation the possessor precedes the possessed (Twi *nipa dua* "a man's figure," Kunama *lla masa* "Ila's lance"). (8) There is no formal distinction of case. The dative form is circumscribed by the verb "to give" (Ewe *edi ga na fofo* "he sought money gave father": he sought money for the father. Nuba *ir iga tir onam* "you say give him": you say to him. (9) Postpositions, *i.e.*, space-denoting nouns, are used in the place of prepositions (Ewe *ati ta* "tree's head": on the tree; Nuba *ka tu* "house's belly": in the house. (10) Verbal combinations are frequent (Ewe *tso va na* "take come give": to bring to; Nuba *atta-den* from *ed-ta-den* "take come give": to bring to). (11) The verbal stem is not changed in conjugation; tenses and modes are expressed by adding grammatical form words which in many cases can be traced to original nouns or verbs (in Twi the future is formed by prefixing *ba* [from *bia*] "to come," in Nuba by prefixing *bi* "to come"). (12) Sounds peculiar to the majority of Sudanic languages are the labio-velar *kp* and *gb*. (13) A considerable number of word-stems are identical. The characteristics just mentioned are not found in each sub-group, but there is no group which does not possess a number of them.

Divisions.—The Sudanic family may be geographically divided into an eastern, a central and a western group. The largest section of the eastern group are the Niloto-Sudanic languages comprising Shilluk with its many subdivisions, Dinka, Nuer and probably also Burun between the White and Blue Niles. Nuba on the Nile, in the Nuba mountains and in Kordofan, is connected with the Nilotic group, while other languages of these mountain regions are of a distinct character, having a class division of the noun.

The central group stretches between the 30th and 10th degree east long, and is subdivided by Delafosse into (a) Nile-Congo group, which, however, contains languages that are more closely related to the eastern Sudanic group; (b) Ubangi group; (c) Shari-Wadai group; (d) Shari group; (e) Niger-Tshad group; (f) Niger-Camerouns group. Our present knowledge concerning the central Sudanic group is so insufficient that the grouping just given is only provisional.

The western Sudanic group is better known and the sub-groups are well-defined. They are the following: (1) *The Kwa languages*, spoken on the coast of Upper Guinea between the lower courses of the Niger and St. Paul's River in Liberia. Their sub-groups are: (a) Ewe-Akan group (Gold Coast, Togo, Dahome); (b) Lagoon group in the littoral regions of the Ivory Coast; (c) Kru group, reaching from the western Ivory Coast to the mouth of St. Paul's River; (d) Yoruba group; (e) Nupe group; (f) Ibo group; (g) Edo group; (h) Ijo (*d-h* in Nigeria). In the Kwa

languages the majority of word-stems consists of one consonant and one vowel. Akan *ka* "to remain," *wu* "to die." They have vocalic and nasal nominal prefixes, whose function is to form nouns out of verbs, and which are only absent in Kru. The prefixes do not form class divisions of the noun, except in rudiments.

(2) *Benue Cross River languages*. They partly coincide with Delafosse's Niger-Cameroons group and with Johnston's group A in his Bantu and Semi-Bantu languages, group (b) including Johnston's groups B-G, and group (c) comprising Johnston's group H. The languages of this group have many stems which end in a consonant. Efik *wut* "to kill" against Ewe *wu* "to kill." They have the same nominal prefixes as in group (1) (Efik *fime* "to blow," *o-fime* "wind"), but some languages have a system of prefixes which forms classes. As the group lies on the borderline between Sudanic and Bantu, some of its languages represent a stage of transition between the two.

(3) *Middle Togo group*. Most of these occupy a very small area, being situated in the mountainous region between the 7th and 8th degree N. lat.; some of them are disappearing or have already disappeared, being absorbed by Ewe and Akan. Among those which continue to exist are Avatime, Likpe, Adele, Kposso, Kebu. The word-stems in this group consist mainly of one consonant and one vowel. Kposso *wu* "to kill." A class division of nouns is formed by prefixes; some languages use class-suffixes besides the prefixes. The group stands between groups (1) and (4), having distinct connections with both.

(4) *Gur (Goor) languages*, in the northern section of the Ivory and Gold Coast, of Togo and of Dahome, and in the adjacent parts of Haute Volta. They include the following sub-groups: (a) Mossi group (Mossi, Dagomba, etc.), (b) Grussi or Gurunsi group, (c) Tem group, (d) Bargu, (e) Gurma group, (f) Kilina, (g) Senufo or Siena group, (h) Songai. The latter is in fact an isolated language having its own type, but is remotely connected with the Gur languages. Stems of the form consonant plus vowel are very frequent, though perhaps not in the majority. Dyan *wu* "to kill." All have class division of nouns by suffixes; Gurma and Tem use prefixes and suffixes.

(5) *West Atlantic languages*. These are found in part of the territory between the Senegal and the Atlantic, with a number of enclaves farther east, and are sub-divided into an eastern group, comprising Temne, Bulom, Limba, Kissi, Gola and Adjukru, and a western group, represented by (a) Dyola, (b) the Bissao-Bolama cluster (Bola, Sarar, Pepel, Kanyop), (c) the Geba cluster (Biafada, Padjade), (d) Banyun, Nalu, Bulanda, (e) Konyagi, (f) Bidjogo, (g) Wolof and Serer. Neither in general type nor in phonology and etymology do the members of this group form such a close unit as those of the preceding group. Almost all have class division of nouns; some, as Bulom, Temne, Adjukru, by prefixes, Gola by prefixes and suffixes, Wolof and Serer have suffixes, but also change the beginning consonant, which perhaps points to prefixes. Stems consisting of a consonant and a vowel are frequent (Bulom *wu* "to die"), but they are in a minority.

(6) *Mandingo or Mande languages*, in the western Sudan between groups (4) and (5). They fall into two groups, named after the numeral for "ten" prevailing in each group: (a) *Mande tan*, with Bambara, Soninke, Malinke, Dyula, as main representatives, (b) *Mande ju*, comprising Susu, the Kpelle-Mende cluster, in Sierra Leone and Liberia (Mende, Kpelle, Gbande, Gbunde, Toma, Mano, Gio), Djalonka in French Guinea, and a number of small languages reaching as far east as the north-west corner of Nigeria (Boko-Busa). In the Mandingo tongues two-syllabic words prevail; many of these are compositions of two mono-syllabic stems, each consisting of a consonant and a vowel. There are no word-forming prefixes, except in rudimentary forms. The word may often have a verbal and a nominal meaning: Bambara *ti* "thatch" and "to thatch."

Bantu Languages.—These, spreading through the southern half of the continent, form a closely united family with clearly defined features. Though the most prominent of these, the class division of nouns by prefixes, also exists in Sudanic groups, it has in Bantu reached a fuller development and has become the

dominating factor in their structure. These prefixes also form the plural; thus *m-swahili* a Swahili, *wa-swahili*, Swahili people, *ki-swahili* the Swahili language. The prefix belonging to a noun is repeated (though sometimes in a changed form) before every adjective, noun or pronoun agreeing with the noun; Swahili: *ki-su ki-kali ki-moja ki-me-potea* "knife sharp one has been lost": one sharp knife has been lost; *-su* "knife" has *ki-* as its class prefix, and this is repeated before every word agreeing with *-su*. The plural prefix corresponding to *ki-* is *vi-*; thus the plural of the preceding sentence is: *vi-su vi-kali vi-nane vi-me-potea* "eight sharp knives have been lost." The main nominal classes are: (a) for "man as an independent personality"; (b) for "man in dependent position" (slave, messenger, workman), also for physical agents, spirits, diseases, parts of the human body, animals, plants; (c) for objects existing in double or divisible form, the plural also designating collectives and liquids; (d) for "customs, usages, tools"; (e) for animals; (f) for individual objects and abstract nouns; (g) for diminutives; (h) for infinitives; (i) (or rather three) for locatives. Clicks (probably borrowed from Bushman and Hottentot) and lateral sounds are peculiar to some South African Bantu languages. Intonation is in most tongues not so important as in the Sudanic family. Stress accent is more developed than in the latter, the accent lying generally on the penultimate. Two-syllabic stems are prevalent. There is no grammatical gender, sex being indicated as in Sudanic languages, and no case inflection. The genitive follows the governing noun. The verb has a large number of derivative forms, which afford a remarkable richness in expression, e.g., Swahili *vunja* "to break," *vunjika* "to be broken"; *penda* "to love," *pendana* "to love each other"; *takata* "to be clean," *takasa* "to cleanse"; from *pata* "to obtain" the following derivatives may be formed: *patana* "make an agreement," *patanisha* "unite," *patia* "obtain for somebody," *patika* "be seized," *patilia* "reach out for something," *patiliza* "make one vexed," *patilizina* "vex each other."

It is more difficult to group the Bantu languages in subdivisions than the Sudanic languages, where the evolution of independent types is evident at first sight.

According to Homburger, Bantu is divided into the following groups (of the individual languages belonging to each group only a certain number can be mentioned here): (1) Northern or Ganda group (Ganda, Nyoro, Kerewe). (2) Ruanda group (Ruanda, Rundi). (3) North-eastern or Kilimanjaro group (Kikuyu, Kamba, Djagga, Moshi, Siha). (4) Northern group of the east coast (Taveta-Taita, Chassu, Pokomo, Nika, Shambala, Bondei, Zigula, Swahili, Comore, Zaramo, Kami, Matumbi). (5) East African group (Nyamwezi, Nyaturu, Gogo, Hehe, Pogoro, Kaguru, Konde, Yao, Nyanja, Sene, Tete, Chwabo or Kilimane). (6) South-eastern group (Makua, Ronga or Thonga, Gwamba or Hlengwe, Chopi or Lenge, Venda, Sotho, Kololo, Chwana). (7) Zulu group (Kafir or Xosa, Zulu, Tebele, Ngoni). (8a) Central group (Tabwa, Bemba, Mambwe, Bisa or Wisa, Lala-Lamba, Senga, Tonga, Subiya). (8b) Western group (Herero, Ndonga, Kwanyama, Nyaneka, Mbunda, Luyi, Umbundu, Kimbundu, Lunda, Luba or Lua). (9) Congo group (Congo, Kanioka, Kutsu, Kele, Lolo, Nkundu). (10) North-western group (Bangi, Teke, Kalai or Kele, Galoa, Duma, Benga, Noho, Basa, Duala, Bube, Kwiri, Isubu). This division appears to call for a new investigation based on a careful observation of sound-shifting, for which a good start has been made by van Warmelo in his study on South African Bantu languages.

Hamitic Languages.—These represent a linguistic type which is more closely allied with the Semitic than with any other group of African languages. Their main divisions are (1) Eastern Hamitic in north-east Africa, including, among others: Bedauey, Bogos, Danakil, Somali, Galla, Agau, Kaffitsho. (2) Niloto-Hamitic: Masai, Ndorobbo, Tatoga, Nandi, Suk, Turkana, Gimirra. (3) Western Hamitic: The Berber dialects from western Morocco to the oasis of Siwa, Tuareg, and probably the extinct language or languages of the Guanches on the Canary islands. Hausa (*q.v.*), may be called a remoter member of this sub-group. Though it has adopted many elements from neighbouring Sudanic tongues,

its Hamitic affinity cannot be doubted. Hottentot in South Africa also shows certain Hamitic features, but recent investigations, especially those undertaken by Schapera, reveal such undeniable affinities between the Hottentot and Bushman languages (*q.v.*), as can hardly be explained by borrowing, but seem to point to a genetic relation between the two. Distinction of sex, always one of the prominent reasons for including Hottentot in the Hamitic family, is also found in Naron, a Bushman tongue, being in both cases expressed by a suffix. Both Nama and Naron have a dual form besides singular and plural, *|xam* and Nama have inclusive and exclusive forms of the first person plural (including or excluding the person addressed). There are other common features in grammar and a considerable number of words common to both. Schapera's conclusion is "that in spite of the many noticeable differences between them the Hottentot and Bushman tongues must be regarded as belonging to one and the same family of languages."

The characteristic features of Hamitic speech are: (1) Grammatical gender. Shilh masc. *idilli*, fem. *t-idilli-t* "black," Masai *ol dia* "male dog," *en dia* "female dog," Nama *khoib* "man," *khois* "woman," Hausa *ya* "he," *ta* "she." (2) a richness in plural formation, which may form such distinctions as distributive, collective, general and universal plurality. Bilin *dimmū-rā* "an individual of the cat family," pl. *dimmū-t*; but: *dimmū* "cat," pl. *diāmū* "cats." Chamir *ieslemā* "a Muslim," pl. *ieslem-en*, but *ieslem-en-t* "the Muslim world." In Hausa (*q.v.*), most nouns have several plural forms; *kunba* "finger-nail" has the plural forms *kundōbī*, *kunbuna*, *kunbai*, *kunbaibai*. Here as in other Hamitic (and Sudanic) languages re-duplication is frequently used in forming the plural. (3) Inner vowel change (ablaut): Shilh *iliwi*, pl. *ilaw-an* "thorn"; *a-fulu*, pl. *i-fel-en* "string" (the changes are, however, caused by vowel-assimilation, and are thus a phenomenon found likewise in Sudanic languages); in verbs: Shilh *of-aji* "I find," *ufi-ji* "I have found." (4) As in Bantu, the genitive follows the governing noun. In Hottentot, however, as in Bushman and Sudanic (and also Bedaue), the possessor precedes the possessed.

Fulfulde.—Meinhof includes Fulfulde, the language of the Fulbe, in the Hamitic family, but calls it Proto-hamitic or Pre-hamitic. Fulfulde has the usual Hamitic genitive position, in which the governing noun precedes the genitive, but other features regarded as Hamitic are absent. Fulfulde has no grammatical gender; there is no different plural form of nouns, and there is no inner vowel change. It is decidedly a class language, *i.e.*, like Bantu and many Sudanic languages it divides nouns into classes by affixes, and this fact separates Fulfulde from the Hamitic stock and draws it near Bantu languages and the Sudanic class languages. The connection between Fulfulde and Bantu is recognized by Meinhof, his opinion being that "originally in the whole of the present Bantu region languages of a Sudanic type were spoken, until from the north tribes with a language similar to Fulfulde penetrated and made themselves lords over the old inhabitants. The result of a mixture of these two elements was Bantu." (c D. Kolonial-Lexikon i. p. 133.) The essential identity of the class-affixes as used in Fulfulde, in Sudanic class languages and in Bantu, in their etymological form as well as in their function, is evident, while in point of vocabulary Fulfulde and Bantu differ widely.

On the other hand there is an original affinity between Bantu and Sudanic languages. This refers not only to class-affixes, but also and still more to etymology. The two families have a considerable number of word-stems in common, and also certain formative elements, apart from class-affixes, are identical in both families.

The situation may be summed up as follows: The Negro population of Africa, comprising the Bantu and the Sudanic speaking peoples, has in etymology and in a number of formative elements a common linguistic substratum. The class division of nouns existing in Fulfulde, in Bantu and in certain Sudanic languages is evidently of common origin, where or from what language it may have originated we do not know.

According to Struck, the number of African languages is as

follows: Bushman 11, Sudanic 264, Bantu 182, Hamitic 47, Semitic 10. Many of these occupy a small area, and perhaps not more than 12 are spoken by more than a million people. From the practical point of view, some of the most important African languages are (Semitic): Amharic, Arabic; (Hamitic): Hausa; (Bantu): Ganda, Kikuyu, Kongo, Luba-Lulua, Mbundu, Ngala, Nyanja, Sukuma-Nyamwezi, Ruanda-Rundi, Sotho-Pedi-Chwana, Swahili, Swina-Karanga-Ndau, Zulu-Xosa; (Sudanic): Akan, Dinka-Nuer, Efik-Ibibio, Ewe-Aneho-Dahome, Ibo, Kanuri, Kpelle-Mende, Malinke-Djula-Bambara, Mossi-Dagomba, Nupe-Ghari, Temne, Wolof, Yoruba, Zande.

AFRICAN LILY (*Agapanthus umbellatus*), a member of the family Liliaceae, a native of the Cape of Good Hope, whence it was introduced at the close of the 17th century. It is a handsome greenhouse plant, which is hardy in the south of England and the milder parts of the United States. It has a short stem bearing a tuft of long, narrow, arching leaves, $\frac{1}{2}$ to 2 ft. long, and a central flower-stalk, 2 to 3 ft. high, ending in an umbel of bright blue, funnel-shaped flowers. The plants are easy to cultivate, and are generally grown in large pots or tubs which can be protected from frost in winter. During the summer they require plenty of water, and are very effective on the margins of lakes or running streams, where they thrive admirably. They increase by offsets, or may be propagated by dividing the root-stock in early spring or autumn. A number of forms are known in cultivation.

AFRICANUS: *see* SCIRPO.

AFRICANUS, SEXTUS IULIUS, a Christian traveller and historian of the 3rd century, was probably born in Libya and lived at Emmaus. He may have served under Septimius Severus against the Osroenians in A.D. 195. He wrote a history of the world (*Χρονογραφίαι*, in five books) from the creation to A.D. 221, calculating the period between the creation and the birth of Christ as 5,499 years, and ante-dating the latter event by three years. This method of reckoning, known as the Alexandrian era, was adopted by almost all Eastern Churches. The history, which had an apologetic aim, is no longer extant, but copious extracts from it are to be found in the *Chronicon* of Eusebius. There are also fragments in Syncellus, Cedrenus and the *Paschale Chronicon*.

Eusebius also gives a letter to Aristides, and one to Origen, impugning the authority of the book of Susanna. The ascription to Africanus of the *Κεσολ*, a work on agriculture, natural history, military science, etc., has been disputed. Neander suggests that it was written by Africanus before he had devoted himself to religious subjects. For a new fragment of this work see *Oxyrhynchus Papyri* (Grenfell and Hunt), iii. 36 *et seq.*

Chronographie* (Leipzig, 1880-85); G. Krüger, *Early Christian Literature*, 248-53; A. Harnack, *Altchristl. Litt. Gesch.*, i. 507, ii. 70.

AFRIDI, the most powerful of the Pathān tribes which hold the mountainous borderland of the N.W. Frontier Provinces, India, though less numerous than the Wazirs. They occupy the eastern spurs of the Safed Koh. Through the north of these runs the Khyber pass, and their centre is the great upland country called Tirāh, 6,000 or 7,000 ft. above sea-level, of which the Orakzais hold the southern half. The Afridi borders are the Peshāwar district on the east and north, the Mohmands on the north, the Shinwāris on the west, and the Orakzai and Bangash on the south, including the valleys of Bārā and Bāzār. The origin of the Afridis is unknown. They have a curiously Jewish cast of features, but have been supposed to be the Aparytai of Herodotus, though for over 2,000 years their history is untraceable. It is, however, certain that about the 15th century they ousted the Tirāhis, doubtless absorbing some of their elements, but their conquests were encroached upon by their neighbours, and it was not until Jahāngir's reign that they retook half of Tirāh from the Orakzai. Under Akbar they embraced the Roshania heresy, but after its suppression they enlisted freely in the Mughal armies and were subsidized to keep open the Khyber pass. But they failed to defend it against Nādir Shāh, and were content to levy toll on such trade as filtered through it during the Abdālī and Sikh *régimes*. On the British annexation their independence was respected, in spite of their appeal to the Indian government to take Tirāh, and they were subsidized to protect trading caravans travelling through the Khyber, but their internal feuds rendered it unsafe. In 1897 the Afridis enrolled in the Khyber militia made a gallant defence of Landi Kotal, but eventually surrendered. The defection of one of their most turbulent clans the Zakka Khel soon involved the whole tribe and the Orakzai as well. This necessitated a regular invasion of Tirāh under Sir William Lockhart, and after much hard fighting every part of the country was traversed and surveyed, all the disaffected sections of the tribes being punished, the Zakka Khel being the last to submit. In 1908 an expedition had again to be launched against the Jawakki Khel. The Afridis are intensely democratic, the heads of clans having little authority, so that raiders cannot be brought to book or tribal engagements enforced. Though brave and hardy the tribe is reputed cruel and untrustworthy, but it has furnished many good soldiers in the Indian army. (H. A. R.)

ORIENT AND OCCIDENT PHOTO

ON THE INDO-AFGHAN
BORDER, WITH HIS HOME-
MADE "MAUSER"

Military Operations.—There have been several British expeditions against the separate clans:—

(1) Expedition against the Kohat Pass Afridis under Sir Colin Campbell in 1850. The British connection with the Adam Khel Afridis commenced immediately after the annexation of the Peshāwar and Kohat districts. Following the example of all previous rulers of the country, the British agreed to pay the tribe a subsidy to protect the pass. But in 1850 1,000 Afridis attacked a body of sappers engaged in making the road, killing 12 and wounding six. It was supposed that they disliked the making of a road which would lay open their fastnesses to regular troops. An expedition of 3,200 British troops was despatched, which traversed the country and punished them.

(2) Expedition against the Jowaki Afridis of the Bori villages in 1853. When the Afridis of the Kohat Pass misbehaved in 1850, the Jowaki Afridis offered the use of their route instead; but they turned out worse than the others, and in 1853 a force of 1,700 British traversed their country and destroyed their stronghold at Bori. The Jowaki Afridis are a clan of the Adam Khel, who inhabit the country lying between the Kohat Pass and the river Indus.

(3) Expedition against the Aka Khel Afridis under Colonel Craigie in 1855. In 1854 the Aka Khels, not finding themselves admitted to a share of the allowances of the Kohat Pass, commenced a series of raids on the Peshawar border and attacked a British camp. An expedition of 1,500 troops entered the country and inflicted severe punishment on the tribe, who made their submission and paid a fine.

(4) Expedition against the Jowaki Afridis under Colonel Moccatta in 1877. In that year the government proposed to reduce the Jowaki allowance for guarding the Kohat Pass, and the tribesmen resented this by cutting the telegraph wire and raiding into British territory. A force of 1,500 troops penetrated their country in three columns, and did considerable damage by way of punishment.

(5) Expedition against the Jowaki Afridis under Brig.-General Keyes in 1877-78. The punishment inflicted by the previous expedition did not prove sufficiently severe, the attitude of the Jowakis continued the same and their raids into British territory went on. A much stronger force, therefore, of 7,400 British troops, divided into three columns, destroyed their principal villages and occupied their country for some time, until the tribe submitted and accepted government terms. The Kohat Pass was afterwards practically undisturbed.

(6) Expedition against the Zakka Khel Afridis of the Bazar valley under Brig.-General Tytler in 1878. At the time of the British advance into Afghanistan, during the second Afghan War, the Zakka Khel opposed the British advance and attacked their outposts. A force of 2,500 British troops traversed their country, and the tribesmen made their submission.

(7) Expedition against the Zakka Khel Afridis of the Bazar valley under Lieut.-General Maude in 1879. After the previous expedition the Afridis of the Khyber Pass continued to give trouble during the progress of the second Afghan War, so another force of 3,750 British troops traversed their country, and after suffering some loss the tribesmen made their submission. After this both the Khyber and Kohat Passes were put on a stable footing, and no further trouble of any consequence occurred in either down to the time of the frontier risings of 1897, when the Afridis attacked the Khyber Pass, which was defended by Afridi levies.

(8) For the Tirāh campaign of 1897 see **TIRĀH CAMPAIGN**.

(9) In February of 1908 the restlessness of the Zakka Khel again made a British expedition necessary, under Sir James Willcocks; but the campaign was speedily ended, though in the following April he had again to proceed against the Mohmands, the situation being complicated by an incursion from Afghanistan.

See Paget and Mason's *Frontier Expeditions* (1884); Warburton's *Eighteen Years in the Khyber* (1900).

(C. L.)

AFRIKANDER BOND, a party, founded in Cape Colony by the Rev. S. J. du Toit in 1879, aiming at federating South Africa in one independent republic. The official optional use of

Dutch in parliament and the law courts was secured, but under the leadership of Hofmeyer and the influence of Cecil Rhodes its anti-British sentiments were greatly modified. It was always, however, essentially an organization for the promotion of the political supremacy of the Cape Dutch. (See also HOFMEYER, JAN HENDRIK; CAPE COLONY; and SOUTH AFRICA, UNION OF.)

AFTERBIRTH, a term used to include the placenta, foetal membranes and umbilical cord. They are usually expelled from the womb in a single mass 15 to 30 min. after the birth of the child. The placenta is a soft, beefy red disk, about 8 to 10 in. in diameter and 1 to 1½ in. in thickness. It is the organ by which the mother nourishes the child and is composed largely of capillary loops from mother and child, in close contact. While the mother's blood does not pass into the blood vessels of the child, the constituents necessary for growth pass through the capillary walls into the child's circulation by a process called osmosis, while the waste products in the foetal blood pass in the other direction and are eliminated by the mother. One surface of the placenta is attached to the inside of the womb, whence it draws its maternal blood. The other surface presents the branching blood vessels of the foetus which unite into one artery and two veins. These vessels form the umbilical cord, which usually starts from the middle of the placenta and enters the body of the foetus at the navel. It is about 22 in. long. Around the edge of the placenta can be found the thin torn membrane which envelops the foetus in the womb. It forms the water bag in which the foetus floats, and usually breaks shortly before the birth of the child. If, however, the child is born with the membranes intact, he is said to be born in a caul.

AFTER-DAMP, in coal-mining, a name given to the poisonous choking gas which forms after a mine explosion. It mainly consists of carbon dioxide, and is also known as choke-damp. (See CHOKE-DAMP.)

AFTERGLOW, a broad high arch of radiance or glow seen occasionally in the western sky above the highest clouds in deepening twilight, or reflected from the high snowfields in mountain regions long after sunset. It is caused by very fine particles of suspended dust in the high atmosphere exercising a scattering effect upon the components of white light. After the eruption of Krakatoa in 1883, a remarkable series of red sunsets appeared all over the world. These were consequent on the spread by atmospheric currents of huge quantities of fine volcanic dust.

AFTER-IMAGE, the immediate recurrence of a sensation, in like or opposite quality, after the removal of its stimulus. After-images are most prominent in vision. If a person gazes steadfastly at a small coloured object for half a minute and then turns his eyes away to a neutral background, he will notice a small coloured spot of complementary hue and brightness. These are called *negative* after-images. If the object was red, the after-image is bluish green; if it was emerald green, the after-image is pink; if it was dark, the after-image is light. *Positive* after-images resemble the stimulus in brightness and hue and usually last only a few seconds. They are favoured by intense illumination in the stimulus, occurring after the eye has been in the dark. Positive after-images occur for pressure, temperature, and the sensations of bodily movement and posture. There are no after-images from sounds or odours.

AFTER-WORK, an expression used in Italy for the organized sociological efforts to provide for the better enjoyment and employment of the leisure created by the contraction of the working day. (See DOPOLAVORO.)

AFZELIUS, ADAM (1750–1837), Swedish botanist, was born at Larf, Västergötland. He founded the Linnaean Institute at Uppsala in 1802, and in 1812 became professor of materia medica at the university. In addition to various botanical writings, he published the autobiography of Linnaeus in 1823.

His brother JOHAN AFZELIUS (1753–1837) known as *Arvidson*, was professor of chemistry at Uppsala; and another brother, PER AF (1760–1843), who became professor of medicine at Uppsala in 1801, was distinguished as a medical teacher and practitioner.

AFZELIUS, ARVID AUGUST (1785–1871), Swedish poet, historian and mythologist. From 1828 till his death he was

parish priest of Enköping. He collaborated with the learned historian, Erik Gustaf Geijer, in the great collection of Swedish folk-songs, *Svenska folksånger från forntiden* (1814–16). He published also translations of the *Sámmunder Edda* and *Herwara-Saga* and a history of Sweden to Charles XII. (of which a German translation was published in 1842), as well as original poems.

AGA or **AGHA**, a word, said to be of Tatar origin, signifying a dignitary or lord. Among the Turks it is applied to the chief of the janissaries, to the commanders of the artillery, cavalry and infantry, and to the eunuchs in charge of the seraglio. It is also employed generally as a term of respect in addressing wealthy men of leisure, landowners, etc.

AGADE, the capital city of "Sargon of Agade." The city is probably identical with Tal-ed-Deir, excavated by Sir E. A. Wallis Budge in 1891. The inscriptions suggest that it was near Sippar, and Langdon identifies it with Sippar-Yakhuru, admitting, however, that the identification is uncertain. At ed-Deir there is a massive city wall forming two sides of a triangle; the third side was formed either by the Euphrates or by a canal. The main gate was at the western apex of the triangle. The city appears to have been constructed all at once, primarily as a fortress. Sargon, who is said to have been a gardener of Semitic origin at Kish, overthrew the Sumerian power of Kish and for some unknown reason changed his capital to Agade.

BIBLIOGRAPHY.—E. A. Wallis Budge, *By Nile and Tigris* (1920); S. Langdon, *Excavations at Kish* (1924).

AGADIR, the best Atlantic harbour of Morocco, 10 km. N. of Wadi Jus. Pop. 2,500. It was the scene of Portuguese fisheries from 1500 and became a valuable commercial centre. Agadir sprang into prominence during the Moroccan crisis of 1911, and since 1912 it has belonged to France.

AGAIAMBO or **AGAUMB**, a race of dwarf marsh-dwellers in British New Guinea, now extinct. In 1904 there were six males and four females, living in huts erected on piles in the lakes and marshes. They lived almost entirely in their "dug-outs" or canoes, or actually wading in the water. Their food consisted of sago, the roots of the water-lily and fish. In features, colour and hair they closely resembled the true Papuans.

AGA KHAN I., HIS HIGHNESS THE (1800–1881), the title accorded by general consent to HASAN ALI SHAH (born in Persia, 1800), when he settled in Bombay under the protection of the British Government. He was believed to have descended in direct line from Ali by his wife Fatima, the daughter of the Prophet Mohammed. Ali's son, Hosain, having married a daughter of one of the rulers of Persia before the time of Mohammed, the Aga Khan traced his descent from the royal house of Persia from the most remote, almost prehistoric, times. His ancestors had also ruled in Egypt, as caliphs of the Beni-Fatimites for a number of years, at a period coeval with the Crusades. Before the Aga Khan emigrated from Persia, he was appointed by the emperor Fateh Ali Shah to be governor-general of the extensive and important province of Kerman. His rule was noted for firmness, moderation and high political sagacity. At last, however, he incurred the mortal displeasure of Fateh Ali Shah. He fled from Persia and sought protection in British territory, preferring to settle down eventually in India, making Bombay his headquarters. In crossing over from Persia through Afghanistan the Aga Khan found opportunities of rendering valuable services to the British army in Afghanistan and thus cast in his lot with the British. A few years later he rendered conspicuous services in the course of the Sind campaign, when his help was utilized by Napier in the process of subduing the frontier tribes, a large number of whom acknowledged the Aga's authority as their spiritual head. When he finally settled down in India, his position as the leader of the large Ismailiah section of Mohammedan British subjects was recognized by the Government, and the title of His Highness was conferred on him, with a large pension. From that time until his death in 1881 the Aga Khan continued to discharge his sacerdotal functions, not only among his followers in India, but towards the more numerous communities which acknowledge his religious sway in Afghanistan, Khurāsān, Persia, Arabia, Central Asia, and even distant Syria and Morocco. He remained throughout

unflinchingly loyal to the British *Raj*, and his vast and unquestioned influence among the frontier tribes on the northern borders of India proved of invaluable service in the several expeditions led by British arms on the north-west frontier of India. He was also able to check the fanaticism of the more turbulent Mohammedans in British India.

He was succeeded by his eldest son, AGA KHAN II. This prince continued the traditions and work of his father and was a member of the legislative council of Bombay.

AGA KHAN III. (1875—) (Aga Sultan, Sir Mohammed Shah), only son of the foregoing, succeeded him in 1885. He was born in 1875, and, under the care of his mother, a daughter of the ruling house of Persia, was given not only that religious and oriental education which his position as the religious leader of the Ismailihs made indispensable, but a sound European training. The Aga Khan headed the Muslim deputation in 1906 to the Viceroy, Lord Minto, which submitted the case for encouraging abandonment of the studied aloofness of their community from Indian political life; and he was president of the All-India Muslim League, thereupon formed, during its first constructive years. He initiated the fund, for raising the Mohammedan college at Aligarh to university status, which was effected in 1920. In the immediate pre-war years he did much to soothe the Indian Muslim sentiment in respect to the Turco-Italian and two Balkan wars. He was touring amongst his followers in East Africa, when the World War broke out, and immediately cabled to the *jamats* or councils of the millions of Ismailihs within British territories and on their borders directing his followers to place themselves unreservedly at the disposal of the British authorities. When Turkey was drawn into the struggle the Aga Khan issued a stirring manifesto showing that the Allies had no overt designs on Islam, and calling upon the Muslims of the empire to remain loyal and faithful to their temporal allegiance. His immediate followers provided a solid phalanx of whole-hearted support of Britain, which had a most steadying influence in sterilizing the efforts of impatient headstrong elements. His influence was reinforced by his close and intimate contact with leading Allied statesmen and the breadth and liberality of his outlook on the problems of reconstruction. His study of Indian and Middle Eastern affairs in *India in Transition* (1918) was not without considerable effect in the final shaping of reforms under the India Act of 1919, and was consistent in broad principle with his post-war criticisms of the British Government's Mesopotamian and Arabian policy.

The Aga Khan joined in many representations, public and private, both at the Peace Conference and subsequently, as to the immense importance to Great Britain, the ruler of the greatest aggregation of Muslims in the world, of not depriving Turkey of a real independent existence. To the G.C.I.E. and the G.C.S.I. already conferred on him there was added in 1916 a salute of 11 guns and the rank and status of a first-class chief of the Bombay Presidency, the only previous instance of the grant of a salute outside the Indian territorial ruling families being that of the first Sir Salar Jung. The Council of State for India recommended him for the Nobel Peace prize in 1923.

AGALMATOLITE, a soft variety of the mineral pyrophyllite (HAlSi_2O_6), also called *pagodite*, used by the Chinese for carving, especially into grotesque figures (whence called "figure-stone").

AGAMEDES (äg-ä-mä-däs), in Greek legend, king of Orchomenus in Boeotia. He and his step-brother Trophonius were skilled architects and constructors of underground shrines and treasure-houses. When building a treasure-house for the Boeotian king, Hyrieus, the brothers fixed one of the stones in the wall in such a manner that they could remove it whenever they pleased and help themselves to the treasure. Hyrieus set a trap in which Agamedes was caught; Trophonius to prevent discovery cut off his brother's head and fled with it. He was pursued by Hyrieus, and swallowed up by the earth in the grove of Lebadeia. On this spot was the oracle of Trophonius in an underground cave; those who wished to consult it, first offered a ram and called upon the name of Agamedes. A similar story is told

of the treasure of Rhampsinitus by Herodotus (ii. 121). The brothers built the temple of Apollo at Delphi. When they asked for a reward, the god promised them one in seven days; on the seventh day they died.

AGAMEMNON, a Homeric hero, son of Atreus, and Aërope, grandson of Pelops, great-grandson of Tantalus and brother of Menelaus. After the murder of Atreus (q.v.), Agamemnon and Menelaus took refuge with Tyndareus, king of Sparta, whose daughters, Clytemnestra and Helen, they respectively married. By Clytemnestra, Agamemnon had three daughters, Iphigeneia (Iphianassa), Electra (Laodice), Chrysothemis, and a son, Orestes. Menelaus succeeded Tyndareus, and Agamemnon, with his brother's assistance, drove out Aegisthus and Thyestes, and recovered his father's kingdom. He extended his dominion

BY COURTESY OF AMERICAN WOMEN'S HOSPITALS

THE TOMB AT MYCENAE, GREECE, KNOWN FOR YEARS AS THE TREASURE HOUSE OF ATREUS, AND CALLED THE TOMB OF AGAMEMNON

by conquest, and became the most powerful prince in Greece. When Paris (Alexander), son of Priam, had carried off his brother's wife, he went round to the princes of the country and called upon them to unite in a war of revenge against the Trojans. He himself furnished 100 ships, and was chosen commander-in-chief of the combined forces. The fleet, numbering 1,200 ships, assembled at the port of Aulis in Boeotia, but was prevented from sailing by calms or contrary winds. Calchas announced that the wrath of Artemis could only be appeased by the sacrifice of Iphigeneia (q.v.). The fleet then set sail. Little is heard of Agamemnon until his quarrel with Achilles (q.v.). After the capture of Troy, Cassandra, the daughter of Priam, fell to his lot in the distribution of the prizes of war. On his return, after a stormy voyage, he landed in Argolis. Aegisthus, who in the interval had seduced his wife Clytemnestra, treacherously slew him with her help, Cassandra also perishing. The murder of Agamemnon was avenged by his son Orestes (q.v.). Agamemnon is quite possibly a more or less historical character, overlord of the Mycenaean or Achaean States of the Greek mainland. In Hellenistic times, at Sparta, he was worshipped under the title of Zeus Agamemnon. His tomb was pointed out among the ruins of Mycenae and at Amyclae.

AGAÑA, the capital and largest city of the island of Guam. The city is situated on the west coast on a low sandy beach that skirts the bay of the same name, and is about 5m. N.E. of Piti, the port of entry for all water shipments, with which it is connected by an excellent road. The population, which is more than 90% native (Chamorro), was 7,432, 1920; 8,690, 1930; municipality 1930, 11,042. The mean annual temperature is about 81°, and is nearly constant throughout the year; the daily variation is small. It is thought that Agaña was an important village before the coming of the Spaniards, who, during their 300 years of occupation, made it the governmental and religious centre of the island. On Feb. 1, 1899, Guam formally passed to the United States and the governor's palace at Agaña became the Government house. Near the centre of the city is the Plaza de España, an open green about 100yd. square, bordered on all sides by rows of coconut palms. About the plaza are situated the Government house, the barracks, Dorn hall, which is used as a public school during the day, the court-house and the Catholic church. Beyond the church is the naval hospital. Agaña has two elementary schools and the only high school in Guam, a modern sewage system, a good water system, an electric light plant, telephones and a cold storage plant.

AGAPĒ, the early Christian love-feast (Gr. ἀγάπη, "Love"). The word seems to be used in this sense in Jude 12, but cf. 2 Pet. ii. 13, where the reading is ἀπάταις ("deceits") for ἀγάπαις. The history of the *agapē* coincides, until the end of the 2nd century, with that of the eucharist (*q.v.*), and Tertullian's detailed account (*Apology*, c. 39) of the *agapē* is not, perhaps, exclusive of an accompanying eucharist: "It is the banquet (*triclinium*) alone of the Christians that is criticized. Our supper (*coena*) shows its character by its name. It is called by a word which in Greek signifies love (*i.e.*, *agapē*). Whatever it costs, it is anyhow a clear gain that it is incurred on the score of piety, seeing that we succour the poorest by such entertainments (*refrigerio*). We do not lie down at table until prayer has been offered to God, as it were a first taste. We eat only to appease our hunger, we drink only so much as it is good for temperate persons to do. If we satisfy our appetites, we do so without forgetting that throughout the night we must say our prayers to God . . . After washing our hands and lighting the lamps, each is invited to sing a hymn before all to God, either taken from holy writ or of his own composition. So we prove him, and see how well he has drunk. Prayer ends, as it began, the banquet."

This evidence is good for Africa. But in Egypt about the same time (180–210), Clement of Alexandria (*Paedagogus*, ii. 1) condemns the "little suppers which were called, not without presumption, *agapē*." This word, he complains, should be used only for the eucharist, not for mere junketings, into which the love-feasts of the church had degenerated. Tertullian too in his tract on fasting (ch. xvii.) mentions grave scandals in connection with the *agapē*.

Ch. xiii. of the tract *About Virginité* (printed among the spurious works of Athanasius) describes a ritual meal which like that in 1 Cor. xi. is *agapē* and eucharist in one, and it is held in a private house, not in church, and the celebrants are holy women.

The historian Socrates (*Hist. Eccl.*, v. 22) records the survival (which he characterizes as singular), around Alexandria and in the Thebaid, of love-feasts combined with the eucharist. So Basil of Cappadocia (Ep. 93), c. 350, states that in Egypt the laity, as a rule, celebrated the communion in their own houses, and partook of the sacrament by themselves whenever they chose. In the old Egyptian church order, known as the *Canons of Hippolytus*, there are numerous directions for the service of the *agapē*, held on Sundays, saints' days or at commemorations of the dead. Chrysostom describes (homily 54, tom. v., p. 365) how after the eucharistic synaxis the faithful remained in church, while the rich brought out meats and drink from their houses, and invited the poor, and furnished "common tables, common banquets, common symposia in the church itself." The Council of Gangra (A.D. 343?) anathematized the over-ascetic people who despised "the *agapēs* based on faith." But the holding of *agapēs* in church was forbidden by the councils of Laodicea (363) and Carthage (under Aurelius, 388–423), and later by the council in Trullo (692). In the age of Augustine the *agapē* was frequent.

In the east Syrian, Armenian and Georgian churches, respectively Nestorian, Monophysite and Greek Orthodox in their tenets, the *agapē* was from the first a survival, under Christian and Jewish forms, of the old sacrificial systems of a pre-Christian age. Sheep, rams, bullocks and fowls are given sacrificial salt to lick, and then sacrificed by the priest and deacon, who has the levitical portions of the victim as his perquisite. In Armenia the Greek word *agapē* has been used ever since the 4th century to indicate these sacrificial meals, which either began or ended with a eucharistic celebration. The earlier usage of the Armenians is expressed in two rules recorded against them by a renegade Armenian prelate named Isaac, who in the 8th century went over to the Byzantine church (Combesius, *Historia Monothelitarum*, col. 317). Older mss. of the Greek Euchologion contain numerous prayers to be offered over animals sacrificed; and in the form of *agapē* such sacrifices were common in Italy and Gaul on the *natalis dies* of a saint, and Paulinus of Nola, in his Latin poems, describes them (c. 400) in detail. Gregory the Great sent to Mellitus, bishop of London, a written rite of sacrificing bulls for use in the English Church of the early 7th century. In Augustine's

work against Faustus the Manichean (xx. 4), the latter taxes the Catholics with having turned the sacrifices of the heathen into *agapēs*, their idols into martyrs, whom they worship with similar rites. The early Christian *agapē* admitted of adaptation to the older funeral and sacrificial feasts, and was so adapted. The association in the synoptics of the earliest eucharist with the paschal sacrifice provided a model, and long after the eucharist was separated from the *agapē* on other days of the year, we still find celebrated on the evening of Maundy Thursday the sacrifice of the paschal lamb, immediately followed by an eucharist. The council of Carthage enacted that the eucharist should be received fasting, except on the anniversary of the Lord's supper. It is clear that at an earlier date the *agapē* preceded the eucharist.

Pagan Analogues.—In ancient states common meals called *sussitia* (συσσίτια) were instituted, particularly in the Doric States; e.g., Lacedaemon and Crete. Plato advocated them, and perhaps the later Jews imitated the Spartan community. Trade and other guilds in antiquity held subscription suppers or *ἐπαυοί*, similar to those of the early Corinthian Church, usually to support the needs of the poorer members. These *hetairiai* or clubs were forbidden (except in cities formally allied to Rome) by Trajan and other emperors, as being likely to be centres of disaffection; and on this ground Pliny forbade the *agapē* of the Bithynian churches, Christianity not being a lawful religion licensed for such gatherings. The custom which most resembles the eucharist and *agapē* was that known as *charistia* described by Valerius Maximus ii. 1. 8: a solemn feast for members of one clan, at which those who had quarrelled were at the sacrament of the table (*apud sacra mensae*) reconciled. Ovid alludes to it (*Fasti*, ii. 617).

AGAPEMONITES or COMMUNITY OF THE SON OF MAN. A sect founded in 1846 by the Rev. Henry James Prince, a clergyman of the Church of England (1811–1899). He studied medicine, obtained his qualifications in 1832 and was appointed medical officer to the general hospital in Bath, his native city. Compelled by ill-health to abandon his profession, he entered himself in 1837 as a student at St. David's theological college, Lampeter, where he gathered about him a band of earnest religious enthusiasts, known as the Lampeter Brethren, and was eventually ordained to the curacy of Charlton in Somerset, where he had sole charge in the illness and absence of the rector, the Rev. Samuel Starkey. His work at this period reveals an almost hypnotic power over his converts; but soon he was mastered by delusions. He persuaded himself that he had been absorbed into the personality of God and had become a visible embodiment of the Holy Spirit. During his illness Mr. Starkey read one of his curate's sermons, and was not only "cured" forthwith, but embraced his strange doctrines, and together they procured many conversions in the countryside and the neighbouring towns. Forbidden the right to officiate in the Church of England, Prince and Starkey established themselves at Weymouth. Money flowed in; and with these resources they obtained the house at Spaxton, which became the "Abode of Love."

On the death of "Brother" Prince, the Rev. T. H. Smyth-Pigott, pastor of the "Ark,"—a branch church established at Clapton, London—became the acknowledged head of the sect. He was born in 1852, of an old Somersetshire county family, and, after a varied career as university man, sailor before the mast, soldier, coffee-planter, curate in the Church of England and evangelist in the Salvation Army, was converted about 1897 to the views of Prince. For five years after this he was not heard of outside his own sect. In Sept. 1902, however, he began to make claims similar to those of his predecessor, and proclaimed himself to be Christ. By the outside world the affair was greeted with mingled ridicule and indignation, and the new Messiah had to be protected by the police from the violence of an angry mob. Scandal was soon renewed through Pigott's relations with his female followers; and in Aug. 1908, an attempt to "tar and feather" him resulted in two men being sent to prison. Later in the month proceedings were instituted against him by the bishop of Bath and Wells under the Clergy Discipline Act.

See Law Reports, Court of Chancery, June 4-8, 1860; art. "Agapemone" in Hastings' *Encyclopaedia of Religion and Ethics*.

AGAPETAE, a name given to female Christian ascetics who dwelt with men under a vow of continency. This practice essentially belongs to the history of Christian asceticism. Its beginnings can be traced in the earliest Christian times, but it was preserved in monasticism down to the early middle ages.

See Hastings, *Encyclopaedia of Religion and Ethics*, "Agapetae"; see also ASCETICISM.

AGAPETUS, the name of two popes:

AGAPETUS I., pope from 535 to 536, collaborated with Cassiodorus in founding at Rome a library of ecclesiastical authors. King Theodahad sent him on an embassy to Constantinople, where he died, after having deposed Anthimus, the Monophysite bishop of that town, and ordained Menas his successor.

AGAPETUS II., pope from 946 to 955, at the time when Alberic, son of Marozia, was governing the independent republic of Rome under the title of "prince and senator of the Romans." He did his best to restore church discipline and to regain temporal power. His appeal to Otto the Great to intervene in Rome remained without immediate effect, since Alberic's position was too strong to be attacked, but it bore fruit after his death. Agapetus died on Nov. 8 955.

AGAPETUS, a deacon of the church of St. Sophia at Constantinople, and author of a series of exhortations on the duties of a Christian prince, addressed (c. 527) to the emperor Justinian. The work was often reprinted, and has been translated into Latin, French and English.

AGAR-AGAR, a vegetable product resembling gelatine and made from various East Indian seaweeds. In China it is used as an ingredient of "bird's nest soup," but its main employment is as a culture-medium for bacteria. It is occasionally utilized also as a laxative.

AGARDE, ARTHUR (1540-1615), English antiquary. As a member of the Society of Antiquarians, he prepared papers for its meetings on such subjects as the origin of parliament, the office and privileges of heralds, six of these essays being printed, after his death, in Thomas Hearne's collection of *Curious Discourses written by Eminent Antiquaries* (1720). Agarde was for 45 years deputy chamberlain of the Exchequer. He bequeathed to the Exchequer his collection of papers relating to that court, and to his friend, Sir Robert Cotton, his other manuscripts, most of which are now in the British Museum.

AGARDH, KARL ADOLF (1785-1859), Swedish botanist, was born on Jan. 23, 1785, at Badstad. He was educated at Lund, where in 1807 he became lecturer in mathematics, and in 1812, professor of botany and rural economy. After being ordained in 1816, he was elected to the diet where, as a leading Liberal, he worked for the promotion of education. In 1834 he became bishop of Karlstad, where he died on Jan. 28, 1859. Agardh's chief works are *Systema Algarum* (1824), *Species Algarum* (1823-28), *Icones Algarum Europaearum* (1828-35), *Essai de réduire la physiologie végétale à des principes fondamentaux* (1828), *Lärobok i botanik*, 2 vols. (1830) and (with Ljungberg)

Försök till en statsekonomisk statistik öfver Sverige, 4 vols. (1852-63).

AGARIC, the name applied to many mushrooms and toadstools (*qq.v.*) from their generic name, *Agaricus* (see FUNGI).

AGAS, RADULPH or **RALPH** (c. 1540-1621), English land surveyor, was born at Stoke-by-Nayland, Suffolk. He is best known for his maps of Oxford (1578), Cambridge (1592) and London. Copies of the first two are preserved in the Bodleian library. Of the map of London and Westminster, which was probably prepared about 1591, two copies have been preserved, one by the Corporation of London and the other in the Pepysian collection at Magdalene college, Cambridge. The map is over 6 ft. long, printed from wooden blocks, and gives a valuable picture of the London of Elizabeth's time.

AGASIAS. There were two Greek sculptors of this name. Agasias, son of Dositheus, signed the statue called the Borghese Warrior in the Louvre. Agasias, son of Menophilus, is the sculptor of another striking figure of a warrior in the museum of Athens. Both belonged to the school of Ephesus and flourished about 100 B.C.

See E. A. Gardner, *Handbook of Greek Sculpture*, ii. p. 475.

AGASSIZ, ALEXANDER EMANUEL (1835-1910), American man of science, son of J. L. R. Agassiz, was born in Neuchâtel, Switzerland, on Dec. 17, 1835. He came to the United States with his father in 1846; graduated at Harvard in 1855, subsequently studying engineering and chemistry, and taking the degree of bachelor of science at the Lawrence scientific school of the same institution in 1857; and in 1859 became an assistant in the U.S. coast survey. Thenceforward he became a specialist in marine ichthyology, but devoted much time to the investigation, superintendence and exploitation of mines, being superintendent of the Calumet and Hecla copper mines, Lake Superior, from 1866 to 1869, and afterwards, as a stockholder, acquiring a fortune, out of which he gave to Harvard, for the museum of comparative zoology and for furthering the study of biology at Harvard and elsewhere upwards of \$1,000,000. In 1875 he surveyed Lake Titicaca, Peru, examined the copper mines of Peru and Chile, and made a collection of Peruvian antiquities for that museum, of which he was curator from 1874 to 1885. He assisted Sir Wyville Thomson in the examination and classification of the collections of the "Challenger" exploring expedition, and wrote the *Revision of the Echini* (1872-74) in the reports. Between 1877 and 1880 he took part in the three dredging expeditions of the steamer "Blake," of the U.S. coast survey, and presented a full account of them in 1888. Of his other writings on marine zoology, most are contained in the bulletins and memoirs of the museum of comparative zoology; but he published in 1865 (with Elizabeth Cary Agassiz, his stepmother) *Seaside Studies in Natural History*, a work at once exact and stimulating, and in 1871 *Marine Animals of Massachusetts Bay*. He died at sea on the "Adriatic" bound for the United States on March 27, 1910.

See G. R. Agassiz, ed., *Letters and Recollections of Alexander Agassiz; With a Sketch of his Life and Work* (Boston, 1913).

AGASSIZ, JEAN LOUIS RODOLPHE (1807-1873), Swiss-American naturalist, geologist and teacher, was born on May 20, 1807, the son of the Protestant pastor of Motier, on the shore of Lake Morat, Switzerland. His father was the last of a long line of clergymen, the first of the series having been driven from France by the revocation of the Edict of Nantes. His mother, Rose Mayor, was a gifted woman from whom especially he inherited his love of animals and plants. In boyhood he spent four years at the gymnasium in Bienne and later attended the academy at Lausanne. He then entered, successively, the universities of Zurich, Heidelberg and Munich. On completion of his academic courses, Agassiz took at Erlangen the degree of Doctor of Philosophy and at Munich that of Doctor of Medicine.

Although as a youth he gave some interested attention to the ways of the brook fish of western Switzerland, his permanent and lifelong interest in ichthyology arose from his being chosen to study the fishes of Brazil. In 1819 and 1820 two eminent naturalists of Munich, J. B. Spix and C. P. J. von Martius, had made an extensive tour in Brazil, bringing back a large collection of

fishes, mostly from the Amazon river. The classification of these species was begun by Spix; he died in 1826, however, and the whole collection was then turned over by Martius to Agassiz. The work was completed and published in 1829, as *Selecta Genera et Species Piscium*. This splendid accomplishment was a monument to youthful industry and enthusiasm, the author being at that time only 22 years old. The study of fish-forms became henceforth the prominent feature of Agassiz's scientific research. In 1830 he issued a prospectus of a *History of the Fresh Water Fishes of Central Europe*, a valuable contribution printed in parts from 1839 to 1842.

The year 1832 proved the most significant in Agassiz's early career, because it took him first to Paris, then the centre of

AFTER "RECHERCHES SUR LES POISSONS FOSSILES"
A FOSSIL FISH, ETCHED ON STONE UNDER AGASSIZ'S SUPERVISION,
AFTER A SPECIMEN DISCOVERED DURING HIS RESEARCHES AT NEUCHÂTEL

general scientific as well as medical research, and afterwards to Neuchâtel where he spent many years of amazingly fruitful effort. While in Paris he lived the life of an impecunious student of the *quartier latin*, supporting himself, helped at times by the kindly interest of friends, such as Humboldt, who soon secured for him a professorship at Neuchâtel, and Cuvier, the most eminent ichthyologist of his time. At Paris his scientific activities largely centred in the Natural History museum of the great park now known as the Jardin des Plantes.

Already Agassiz had become interested in the rich stores of the extinct fishes of Europe, especially those of Glarus in Switzerland and of Monte Bolca near Verona, of which only a few at that time had been critically studied. As early as 1829, Agassiz planned a comprehensive and critical study of these remains. To this end he gathered material wherever possible. His epoch-making work, *Recherches sur les Poissons Fossiles*, appeared in parts from 1833 to 1844. In it the number of named fossil fishes was raised to nearly 1,000, and the ancient seas were made to live again through disclosure of their inhabitants. The great importance of this foundation work rests on the impulse given to the study of extinct life itself. Turning his attention to other extinct animals found with the fishes, Agassiz published in 1839-40 two quarto volumes on the fossil echinoderms of Switzerland, and later (1840-45) his *Études Critiques sur les Mollusques Fossiles*.

From 1832 to 1846 he served as professor of natural history in the University of Neuchâtel, where may still be found evident traces of the activity and enthusiasm of its youngest and most eager teacher. In Neuchâtel he acted for a time as his own publisher, his private residence even becoming a hive of activities. Numerous young men were co-workers with him, dividing between themselves the scanty returns from his lectures and publications. He now began his *Nomenclator Zoologicus*, a catalogue, with references, of all the names applied to genera of animals from the beginning of scientific nomenclature, a date since fixed at Jan. 1, 1758. "This," said Agassiz, "is a work of patience. It is a barrier against the Babel of confusion which threatens to overwhelm the domain of zoological synonymy." The practical value of the compilation can hardly be overestimated.

In 1836 Agassiz began a new line of studies, that of the movements and effects of the glaciers of Switzerland. Several writers had expressed the opinion that these rivers of ice had once been much more extensive, and that the erratic boulders scattered over the region and up to the summit of the Jura mountains, were carried by moving glaciers. On the ice of the Aar glacier he built a hut, the "Hôtel des Neuchâtelois," from which he and his associates traced the structure and movements of the ice. In 1840 he published his *Études sur les glaciers*, in some regards the most important of all his works. In it he was able to show that at a period geologically recent Switzerland was covered by one vast ice-sheet. His final conclusion was that "great sheets of ice, resembling those now existing in Greenland, once covered all the countries in which unstratified gravel (boulder drift) is found."

In 1846 Agassiz was led to visit the United States for the general purpose of studies in natural history and geology, but immediately to give a course of lectures in the Lowell institute in Boston. These were followed by another series in Charleston, and afterwards by lectures both popular and technical in various cities, his brilliant and engaging personality at once winning all hearts. In 1848 he accepted a professorship of zoology at Harvard university, and from that time on became more and more enthusiastically American. Indeed, half his scientific career, and that not the least important, was lived in this country. "He came in a spirit of adventure and curiosity; he stayed because he loved a land where he could think and act as he pleased; a land where nature is rich but tools and workmen are few, and traditions none."

In America his chief volumes of scientific research were the following: *Lake Superior* (1850); *Contributions to the Natural History of the United States* (1857-1863, in several quarto volumes, the most notable being on the embryology of turtles); and the *Essay on Classification*, a brilliant production, which, however, failed to grasp the trend of modern zoology. Besides these extensive contributions appeared a multitude of short papers on natural history and especially on the fishes of America. His two excursions of highest importance were, first, to Brazil in 1865, and second, to California in 1871, the latter trip involving both shores of South America. *A Journey in Brazil* by Mrs. Agassiz and himself, published in 1868, gives a very interesting account of their experiences on the earlier voyage. His most important paper on American fishes dealt with the remarkable group of viviparous surf-fishes of California.

During many years, also, Agassiz was deeply absorbed in his cherished plan of developing at Harvard university a comprehensive museum of research in zoology. This institution, which was established in 1859 and ultimately grew into the present splendid museum of comparative zoology, enjoyed his fostering care during the rest of his lifetime. In America Agassiz's industry and devotion to scientific pursuits were as strongly marked as in Europe, but two other traits here assumed a much greater importance. As a teacher of science he was extraordinarily skilful, certainly the ablest America has ever known. In addition he was personally devoted to his students, who were in the highest sense co-workers with him—"the best friend that student ever had." His warmth of feeling moreover went out equally to colleagues and neighbours. It was said that "one had less need of an overcoat in passing Agassiz's house than any other in Cambridge." Such qualities, endeared him to all, while his amazing command of lucid and picturesque English impressed every listener. He was also as much at home before an audience of labourers or farmers as with the most erudite leaders of research.

Agassiz's method as teacher was to give contact rather than information. He discouraged the use of books except in detailed research. Among his favourite expressions were "If you study nature in books, when you go out-of-doors you cannot find her." "It's not text-books we want, but students. The book of nature is always open." "Strive to interpret what really exists." The result of his instruction at Harvard was a complete revolution in natural history study in America. The purpose came to be not a category of facts taken from others, but the ability, through contact, to gather the needed facts. As a result of his activities

every notable teacher of natural history in the United States for the second half of the 19th century was at some time a pupil of Agassiz or of one of his students.

In the interests of better teaching and of scientific enthusiasm, he organized in the summer of 1873 the Anderson school at Penikese, an island in Buzzard's bay. The details of this remarkable venture, brief in actual period but having a profound effect on science teaching and the precursor of all American summer schools and establishments for marine research, cannot be given here. But "the school of all schools which has had the greatest influence on science teaching in America was held in an old barn on an uninhabited island, 18 miles from the shore; it lasted but three months; it had virtually but one teacher. It existed in the personal presence of Agassiz. When he died, it vanished." (David Starr Jordan, *Agassiz at Penikese*.)

As Agassiz was beyond question one of the ablest, wisest and best informed of the biologists of his day, it is often asked why his attitude towards Darwinism was, throughout all his lifetime, cold and unsympathetic. It seems possible that his position was determined in part by a misunderstanding, but more particularly by his philosophy of biology. He seemed to regard Darwinism as a theory of continued progress instead of one of divergence, tempered by the weeding out of unadapted individuals. He failed to recognize the importance of separation and segregation in the development of new specific forms. He once said that in his studies of fossils he "was on the verge of anticipating Darwinism," but was withheld by the discovery that "we had the higher fishes first." In a sense this was true, for the brain development of the sharks is higher, as a whole, than that of the bony fishes. But the latter are far more specialized in fitness for aquatic life. More important to Agassiz was the fact that in his philosophy each species of animal or plant was in itself "a thought of God." Their homologies or fundamental unities were "associations of ideas in the Divine Mind." He had an intensely religious mind, although he was totally out of sympathy with sects and creeds and the outer shell of Christianity.

In physical appearance Agassiz was a striking figure, nearly six feet tall, compactly built, with noble head and broad handsome face, usually illuminated by an especially charming smile. This last, however, would suddenly turn into a frown in the presence of careless or trivial work or pretence on the part of a student. He married twice. His first wife, Cecile Braun, was the sister of an eminent botanist. In 1850, after his first wife's death, Agassiz married Elizabeth Cabot Cary, of Boston, well known as a writer and as a promoter of the education of women.

Agassiz died on Dec. 12, 1873. He was buried in Mt. Auburn at Cambridge, and by his grave stands a boulder from the moraine of the Lauteraar. At his death, Theodore Lyman, one of his students, wrote, "We buried him from the chapel that stands among the college elms. The students laid a wreath of laurel on his bier and their manly voices sang a requiem. For he had been a student all his life long, and when he died he was younger than any of them."

(D. S. J.)

AGATE, a term applied, not to a distinct mineral species, but to a group of amorphous and crypto-crystalline forms of silica. According to Theophrastus the agate (*ἀχάτης*) was named from the river Achates, now the Drillo in Sicily, where the stone was originally found. Most agates occur in eruptive rocks or ancient lavas where they fill the cavities which were produced by the lib-

eration of gas during the solidification of the molten rock. These agates have a banded structure, successive layers being approximately parallel to the sides of the cavity. A number of varieties of agate are characterized by peculiarities in the shape and colour of the bands, which are seen in sections cut at right-angles to the layers. In riband-agate they are straight or slightly curved. Such an agate with cloudy bands alternating with bands of another colour, the two sets being sharply marked off from one another, is known by the general term onyx. A ring or eye agate is one in which the differently coloured bands are disposed in concentric circles. A Mexican agate, showing only a single eye has received the name of "cyclops." When the banding forms re-entrant and salient angles, its outline resembling that of the plan of a fortress, it is called fortification-agate. Certain agates also occur, to a limited extent, in veins, of which a notable example is the beautiful brecciated agate of Schlottwitz, near Wessenstein in Saxony—a stone mostly composed of angular fragments of agate cemented with amethystine quartz. A variety having included matter of a green colour, embedded in the agate and disposed in filaments and other forms suggestive of vegetable growth, is known as moss agate. Dendritic markings of black or brown colour, due to infiltration of oxides of manganese and iron, produce the variety known as Mocha stone.

It is probable that agates occurring in cavities in igneous rocks have been formed in a number of ways, and various theories of their origin have been proposed. The theory which is now generally accepted is as follows. During the solidification of the rock an accumulation of gas or steam causes a bubble to form. Long after, when the rock has solidified, water carrying silica in solution, probably as alkali silicate, penetrates into the region where the bubble is located. It then diffuses into the cavity and subsequently the solution coagulates to a silica gel. The alkali present with the silica attacks the iron-bearing rock surrounding the cavity, giving rise to iron salts. These diffuse into the silica gel and produce the regular layers of iron hydroxide after the manner of Liesegang's rings. Finally the whole mass gradually hardens with loss of water and crystallization of much of the silica as quartz or chalcedony. During the process of crystallization the coloured bands are not disturbed and hence we have the final agate as it is now found.

Agates are cut and polished chiefly in the Idar-Oberstein district situated on the Nahe, a tributary of the Rhine at Bingen. Here the industry grew up many centuries ago by reason of an abundance of agates in the amygdaloidal melaphyre of the district. The stones used now are mostly imported from Brazil (Rio Grande do Sul) and from Uruguay.

Most commercial agate is artificially stained so that stones naturally unattractive by their dull grey tints come to be valuable for ornamental purposes. The colouring matter is absorbed by the porosity of the stone, but different stones and different layers of the same stone exhibit great variation in absorptive power. To produce a dark brown or black colour, the stone is kept perhaps for two or three weeks in a saccharine solution, or in olive oil at a moderate temperature. After removal from the solution, the agate is well washed and then digested for a short time in sulphuric acid, which, entering the pores, carbonizes the absorbed sugar or oil. Certain layers of chalcedony are practically impermeable and these consequently remain uncoloured, so that an alternation of dark and white bands is obtained, giving rise to an onyx. Agate is stained red, to imitate cornelian and sardonyx, by means of ferric oxide. Other colours are detained in other ways.

Among the uses to which agate is applied may be mentioned the formation of knife-edges of delicate balances, small mortars and pestles for chemical work, burnishers and writing styles, umbrella handles, paper knives, seals, brooches and other ornaments. Real cameos are cut from banded agates, one layer forming the medal-lion, the other the design in relief.

Agates are found in England in the Cheviot Hills, in the neighbourhood of Bristol and at Lichfield in Staffordshire. In Scotland they occur at Montrose in Forfarshire, in Perthshire, and at many other localities. The majority of agates are produced in countries outside Europe, notably in South America, North America and India; they are also found in South Africa and Australia.

Kunz, *Gems and Precious Stones of North America* (1890). For Scottish agates see M. F. Heddle, *Mineralogy of Scotland* (1901).

(W. A. W.)

AGATHA, ST., the patron saint of Catania, Sicily, where her festival is celebrated on Feb. 5. The legend is that she was a native of Sicily (probably of Catania, though Palermo also claims her) of noble birth and great beauty. She repelled the advances of the Roman prefect sent by the emperor Decius to govern Sicily, and was by his orders brutally tortured and finally sent to the stake. As soon as the fire was lighted an earthquake occurred and the people insisted on her release. She died in prison on Feb. 5, 251. The rescue of Catania from fire during an eruption of Mt. Etna was later attributed to St. Agatha's veil.

AGATHANGELUS, AGATHANGE or AKATHANGELOS, Armenian historian, lived during the 4th century, and wrote a *History of the Reign of Dertad, or Tiridates, and of the Preaching of St. Gregory the Illuminator*. This history was translated into several languages, and Greek and Latin translations are found in the *Acta Sanctorum Bollandistarum*, tome viii. The history consists of three parts, a history of St. Gregory and his companions, the doctrine of Gregory, and the conversion of Armenia to Christianity.

See V. Langlois, *Collection des Historiens anciens et modernes de l'Arménie* (Paris, 1868).

AGATHARCHIDES or AGATHARCHUS, of Cnidus, Greek historian and geographer, lived in the time of Ptolemy Philometor (181–146 B.C.) and his successors. Amongst other works, he wrote treatises on *Asia*, *Europe* and *the Red Sea*. Interesting extracts from the last, of some length, are preserved in Photius (cod. 213).

BIBLIOGRAPHY.—See H. Leopoldi, *De Agatharchide Cnidio Dissertatio* (1892); C. W. Müller, *Fragmenta Historicorum Graecorum*, iii., and *Geographi Graeci Minores*, i.; E. H. Bunbury, *Hist. of Ancient Geography*, ii. (1879).

AGATHARCHUS, the name of an Athenian painter of the 5th century B.C. He is said by Vitruvius to have been the first to paint a scene for the acting of tragedies.

AGATHIAS (c. A.D. 536–582), of Myrina in Aeolis, Greek poet and historian. He studied law at Alexandria, completed his training at Constantinople and practised as an advocate (*scholasticus*) in the courts. He wrote a number of short love-poems in epic metre, called *Daphniaca*. He next put together a kind of anthology, containing epigrams by earlier and contemporary poets and himself, under the title of a *Cycle of New Epigrams*. About a hundred epigrams by Agathias have been preserved in the *Greek Anthology*. After the death of Justinian (565), some of Agathias's friends persuaded him to write the history of his own times. This work, in five books, begins where Procopius ends, and is the chief authority for the period 552–558.

Dindorf, *Historici Graeci Minores* (1871); W. S. Teuffel, "Agathias von Myrine," in *Philologus* (i. 1846); C. Krumbacher, *Geschichte der byzantinischen Literatur* (2nd ed. 1897).

AGATHO, pope from 678 to 681, was born in Sicily. He ordered St. Wilfrid to be restored to his bishopric at York in 679, and was the first pope to cease payment of the tribute hitherto paid on election to the emperor at Constantinople. Agatho died on Jan. 10, 681.

AGATHOCLES (361–289 B.C.), tyrant of Syracuse, was the son of a potter, born at Thermae Himeraeae (mod. *Termini Imerese*) in Sicily. He removed to Syracuse and served with distinction in the army. In 333 B.C. he married the widow of his patron Damas, a distinguished and wealthy citizen. He was twice banished for attempting to overthrow the oligarchical party in Syracuse (q.v.); in 317 B.C. he returned with an army of exiles and Campanian mercenaries. He banished or murdered some 10,000 members of the senate and the oligarchical party, proclaiming

himself the champion of the people, and thus made himself master of Syracuse. His tyranny was confirmed by a virtually unanimous vote of the people, and, despite his continuous wars, he seems to have been generally popular. He enriched Syracuse with many public buildings, and his reign was looked back to as a period of orderliness and tranquillity. His foreign policy was inevitably part of the almost continuous 200 years' war between the Sicilian Greeks and their secular enemy, Carthage (q.v.). In these wars Syracuse had always taken the lead, and Agathocles only continued the policy of Dionysius the Elder, Dionysius the Younger and Timoleon (qq.v.).

In 310 B.C. Agathocles, defeated and besieged in Syracuse, took the desperate resolve of breaking through the blockade and attacking the enemy in Africa. He besieged Carthage, which was at the time troubled by internal dissensions, but after several victories he was at last completely defeated (306) and fled secretly to Sicily. After concluding peace with Carthage, Agathocles styled himself king of Sicily and established his rule over the Greek cities of the island more firmly than ever. Even in his old age he displayed the same energy and is said to have been meditating a fresh attack on Carthage at the time of his death, which was followed by a recrudescence of Carthaginian power in Sicily. Agathocles was something more than the typical leader of mercenaries. He was a born leader, who knew how to inspire devotion.

BIBLIOGRAPHY.—See Justin xxii., xxiii.; Diodorus Siculus xix., xxi., xxii. (follows generally Timaeus who had a special grudge against Agathocles); Polybius ix. 23; Schubert, *Geschichte des Agathokles* (1887); Grote, *History of Greece*, ch. 97; also *Sicily: History*.

AGATHODAEMON, an early map designer of Alexandria, who probably lived in the 2nd century A.D. Some manuscripts of the *Geography* of Ptolemy contain 27 maps, which are stated to have been drawn by Agathodaemon of Alexandria, who "delineated the whole world according to the eight books of Ptolemy's geography." About 1470, Nicolaus Doris, a Benedictine monk, produced an edition of them in which the names were inserted in Latin instead of Greek.

See Bunbury, *History of Ancient Geography*, ii.

AGATHODAEMON, an important god in Greek mythology, the "good spirit" of cornfields and vineyards, protective spirit of individuals and the State. The Greeks drank a cup of pure wine in his honour at the end of each meal (Aristophanes, *Equites*, 106). Often accompanied by *Agathē Tuchē* (good fortune), he may be compared with the Roman *Bonus Eventus* (Pliny, *Nat. Hist.*, xxxvi., 23) and *Genius* (q.v.). He is represented in works of art in the form of a serpent, or of a young man with a horn of plenty and a bowl in one hand, and a poppy and ears of corn in the other.

AGATHON (c. 448–400 B.C.), Athenian tragic poet, friend of Euripides and Plato. He won his first victory in 416 (at the Lenaea), and his plays seem to have been successful, despite their artificial style. He appears to have been the first to invent an original plot, and to write choral odes unconnected with the plot. His effeminacy made him a butt of Aristophanes. Before 406 he retired to the court of Archelaus, where he died.

See Aristotle, *Poetica* 9, and 18; Aristophanes, *Thesmoph.* 59, 106, *Eccles.* 100; Plato, *Symp.* 198 c.; Plutarch, *Symp.* 3; Aelian, *Var. Hist.* xiv. 13; Ritsch, *Opuscula*, i.; fragments in Nauck, *Tragicorum Graecorum Fragmenta*. See also Haigh, *Tragic Drama of the Greeks*.

AGATHYRSI, a people of Thracian origin, who in the earliest historical times occupied the plain of the Maris (Maros), in the region now known as Transylvania. They are described by Herodotus (iv. 104) as of luxurious habits, wearing gold ornaments (the district is still auriferous) and having wives in common. They tattooed their bodies (Virgil, *Aeneid*, iv. 136), degrees of rank being indicated by the manner in which this was done, and coloured their hair dark blue. Valerius Flaccus (*Argonautica*, vi. 135) calls them Thyrsagetae, probably in reference to their celebration of orgiastic rites in honour of some divinity akin to the Thracian Dionysus. In later times the Agathyrsi were driven farther north, and their name was unknown to the Romans in their original home.

See Pliny, *Nat. Hist.* iv. 12 [26], 88.

AGAVE, a large botanical genus of the family Amaryllidaceae, chiefly Mexican, but occurring also in the southern and western United States and in central and tropical South America. The plants have a large rosette of thick fleshy leaves generally ending in a sharp point and with a spiny margin; the stout stem is usually short, the leaves apparently springing from the root. They grow slowly and flower but once after a number of years, when a tall stem or "mast" grows from the centre of the leaf-rosette and bears a large number of short, tubular flowers. After development of fruit the plant dies down, but suckers are frequently produced from the base of the stem which become new plants. The most familiar species is *Agave americana* (see fig.), a native of tropical America, the so-called century plant or American aloe (the Maguey of Mexico). The number of years before flowering, 5 to 60 or more, but usually about 10, depends on the vigour of the individual, the richness of the soil and the climate; during these years the plant is storing in its fleshy leaves the nourishment required for the effort of flowering. During the very rapid development of the immense peduncle, or flowering stalk, there is a rush of sap to the base of the young flower stalk; by removing this large bud just as it is ready to emerge and by scooping out a cavity in the heart of the plant, a large quantity of sweet sap is obtained; and this *aguamiel*, removed, carried in pig-skin bottles to the central repository, undergoes two kinds of fermentation, and when it has become thick, milky and more or less ropy (the sugars then being changed into alcohol) it is marketed as *pulque* (q.v.), the national drink of Mexico; notwithstanding its objectionable odor and consistency it is by some thought a wholesome and nourishing drink, and many train-loads are brought daily to Mexico City from the vast *pulque* plantations in the surrounding region. By distillation of *pulque fuerte*, or completely fermented juice, a very strong liquor, *mescal*, is obtained.

The leaves of several species yield commercial fibres: *A. rigida elongata* or *A. fourcroydes* is the henequen, or Yucatan sisal, formerly the principal sisal hemp (q.v.). *A. rigida sisalana* or *A. sisalana* is the Bahama sisal, the culture of which is expanding greatly in East Africa and Haiti.

A. cantula is the Maguey, or Philippine sisal.

A. zapupe is the Mexican *Zapupe* fibre.

A. americana produces one of the *Pita* fibres, now grown in southern Europe and parts of the West Indies as well as in Mexico.

A. neglecta is the Florida sisal, one of the largest species, the flower-stalk of which may exceed 42 feet in height.

The firm white pith of the interior of the flowering stem of any of these species, when dried and cut in slices has a variety of uses—as natural razor-strops, as lining of insect-boxes, insulating material, etc. The gummy, soapy juice expressed from the leaves will lather like soap and may be used as a detergent where alkali would be injurious. The thick reddish roots of various species are reputed to have medicinal properties. The concentrated sap exuded into the scooped-out central bud cavity is also used as a medicine and is a source of agavose ($C_{12}H_{22}O_{11}$), one of the rare sugars. In the Madras Presidency the plant is widely used for

LONGITUDINAL SECTION FROM BAILLON, "HISTOIRE DES PLANTES" CENTURY PLANT (*A. AMERICANA*), SO NAMED BECAUSE IT WAS SUPPOSED TO BLOSSOM ONLY WHEN 100 YEARS OLD AND THEN DIE Showing long flower stem and rosette of spiny leaves; vertical section and single flower enlarged

hedges along railroads. *Agave americana* was introduced into Europe about the middle of the 16th century and is now extensively cultivated for its handsome appearance; in the variegated forms the leaf has a white or yellow marginal or central stripe from base to apex. As the leaves unfold from the centre of the rosette the impression of the marginal spines is very conspicuous on the still erect younger leaves.

AGDE, a town of south France, in the department of Hérault, 2½m. from the mouth of the Hérault, and 32m. S.W. of Montpellier on the Southern railway. Pop. (1926), 8,503. It lies at the foot of an extinct volcano, the Montagne St. Loup, and is surnamed "La Ville Noire" from the dark volcanic basalt of which it is built. Agde is said to have been founded as a port by Phocaean under the name of *Agathe*. It was the seat of a bishop from 400 to 1790. Overlooking the river is the old Cathedral of St. Étienne, a grim fortress-like structure of the 12th century. The machicolations of the parapet are said to be the oldest existing instance of the kind. The *Canal du Midi*, uniting the Garonne with the Mediterranean, passes under the town walls. The maritime commerce of the town has declined, because Cette is near and the Hérault shallow, but the fishing industry is still alive. The town has a tribunal of commerce.

SYNOD OF AGDE (*Concilium Agathense*).—The 47 genuine canons of the synod (Sept. 11, 506), dealt with discipline, church life, alienation of ecclesiastical property and treatment of Jews. While favouring sacerdotal celibacy the council laid rather rigid restrictions on monasticism. It commanded that the laity communicate at Christmas, Easter and Whitsuntide. The canons of Agde are based in part on earlier Gallic, African and Spanish legislation; and some of them were re-enacted by later councils.

AGE. The subject of the duration of human and animal life does not fall within the scope of this article, and the reader is referred to **LONGEVITY**. But the word "age" has been used by physiologists to express certain natural divisions in human development and decay. These are usually regarded as numbering five, viz., *infancy*, lasting to the seventh year; *childhood* to the 14th; *youth* to the 21st; *adult life* till 50; and *old age*.

The division of human life into periods for legal purposes is naturally more sharp and definite than it can be for physiological purposes. In Roman law the legal divisions were (1) *infantia* lasting till the close of the seventh year; (2) the period between *infantia* and *pubertas*, males becoming *puberes* at 14 and females at 12; (3) *adolescentia*, the period between puberty and majority; and (4) the period after the 25th year, when males become *maiores*. By English law, life is divided into two main periods—*infancy*, which lasts in both sexes until the 21st year, and manhood or womanhood. The period of infancy, again, is divided into several stages, marked by the growing development both of rights and obligations. Thus at 12 years of age a male may take the oath of allegiance; at 14 both sexes are held to have arrived at years of discretion, and may therefore choose guardians, give evidence, and consent or disagree to a marriage. A female has the last privilege from the 12th year, but the marriage cannot be celebrated until the majority of the parties without the consent of parents or guardians. At 21 both males and females obtain their full legal rights and become liable to all legal obligations. Thus both sexes may enter parliament and be called to the bar, upon attaining majority. In the Church of England, however, a candidate for deacon's orders must be 23 (in the Roman Catholic Church, 22), and for priest's orders 24 years of age; and no clergyman is eligible for a bishopric under 30. In Scotland infancy is not a legal term. The time previous to majority, which, as in England, is reached by both sexes at 21, is divided into two stages: *pupilage* lasts until the attainment of puberty, which the law fixes at 14 in males and 12 in females; *minority* lasts from these ages respectively until 21. *Minority* obviously corresponds in some degree to the English *years of discretion*, but a Scottish minor has more personal rights than an English infant in the last stage of his infancy, e.g., he may dispose by will of movable property, make contracts, including that of marriage, carry on trade and become liable to be declared a bankrupt. Throughout the British Empire the age of majority is usually 21, but the

nubile age is 20 in the Channel Islands; 18 in New Brunswick and Ontario; 18 for females in the North-West Territories and 15 for native females in Fiji. In Belgium and France the age of majority is 21, and the nubile age 18 for males and 15 for females, but marriage cannot be contracted without the consent of the parents or guardians if the parties are under 25. The age of majority is in Argentina 22; in Chile, Spain and Austria 24; in China 20; in Brazil, Denmark, Holland, Germany, Greece, Italy, Mexico, Norway, Peru, the Philippines, Poland, Portugal, Rumania, Sweden, Switzerland and Tunis, 21. In Denmark the nubile age is 18 for males and 16 for females; in Germany 20 for males and 16 for females, subject to the consent of the parents or guardians, and without such consent the males must be 25 and the females 24. But a person of 18 may be declared of full age by a competent court. In Spain majority is reached at 23; the nubile age is 18 for males and 16 for females. In Greece the nubile age is 16 for males and 14 for females; in Holland 18 for males and 16 for females; in Italy 18 for males and 15 for females; in Switzerland 21 for males and 19 for females, but the canton authorities may in extraordinary cases reduce these figures to 19 and 18 respectively. Marriage by minors is subject to the consent of their parents or guardians.

By the constitution of the United States the President must be not less than 35; a senator not less than 30, and a representative not less than 25 years of age. The age of majority, as a rule, is 21 for both males and females, but in Arkansas, California, Colorado, Dakota, Idaho, Illinois, Iowa, Kansas, Maryland, Minnesota, Missouri, Nebraska, Nevada, Ohio, Oregon, Vermont and Washington females attain majority at 18. In Maryland, Oregon, and Texas a female attains majority upon marriage. In Iowa Texas and Louisiana both males and females attain majority upon marriage, and in Washington a female minor married to a male of age is regarded as herself of full age. (H. H. L. B.)

AGE-GRADES means a system of compulsory association or classification by age and sex, whereby groups of coevals are admitted by a series of initiatory rites of varying complexity, including generally the payment of a due, into a tribal association with definite functions both within the age-group itself and in relation to the tribe as a whole, promotion to higher degrees, where such exist, being at regular intervals jointly compulsory on all the individuals comprising a group.

Though superficially resembling secret societies (*q.v.*), and though the ritual of initiation and subsequent ceremonies and esoteric beliefs are secret where a knowledge of them is confined to those who have been initiated and is moreover commensurate with the degree of their initiation, age-grades are differentiated from other forms of association, including secret societies, by the following distinctive features: (1) Admission depends primarily on age and is associated with puberty rites. (2) Every member of the tribe must be affiliated to the system at the proper age. (3) There is no individual admission, but groups of coevals are jointly initiated. (4) Promotion to higher degrees of initiation is similarly compulsory and automatic with the passage of years, even when fees have to be paid or further rites have to be undergone. (5) The system is strictly unilateral, confined to males, though a corresponding institution for females may exist but, where it exists, functions independently. (6) The system is democratic.

Primitive societies are conspicuously divided vertically into families and clans and are horizontally stratified by a variety of associations: religious, occupational, political, social, and so on. Distinction by age and sex cuts across the bonds of consanguinity and creates a new orientation of social activity. Mere classification by age or sex, however, does not of itself indicate an age-grade, for a variety of other factors is involved. A physiological classification of a tribe into boys, youths, adults and old men, with their feminine counterparts, stereotyped by custom into a conventional nomenclature, often lacks the distinctive sociological features of an age-grade: just as we find puberty (*q.v.*) rites in almost all primitive societies, whereas age-grades, though associated with puberty ceremonies and retaining them as an essential element in the complex, are comparatively rare.

Many of the institutions which are reported from different

parts of the world, though analogous to age-grades, differ in one or more essential factors and are therefore to be excluded from this survey. Such institutions are found in Australia, New Guinea, in the Banks Islands, among some of the Naga tribes of Assam, and in certain American Indian societies. The *aluzhi* of the Sema Naga, for instance, are working gangs, with few sociological obligations on the members. They are bisexual, coequality is not essential, and members can be ejected from the group. When clan feeling runs high in a community the *aluzhi* groups break up, indicating that the lateral stratification of society has not the same validity as the vertical. In short, all the essentials of an age-grade are lacking. The Kimta of Bartle Bay, though it has a superficial resemblance to an age-grade, admits of individual members being degraded or promoted to lower or higher degrees, thus invalidating the paramount theory of group-solidarity. Again, though age is the theoretical basis of Banks Islands' societies it is in fact an unimportant factor, and at every stage of initiation except perhaps the lowest, increasingly prohibitive admission fees have resulted in "a commensality of varying years and vastly different social prospects." This is no less true of America and even in the military societies of the Hidatsa, which approach nearest to the definition, the bases of membership are purchase and age, and group-promotion is not automatic but depends on purchase.

Only in Africa, and within a limited area, is the true age-grade system found functioning as a sociological element in tribal life and of the utmost importance. Nowhere do we find age-grades and secret societies concurrently, for secret societies are associated with the evolution of monarchies and powerful aristocracies, which they both limit and reinforce, whereas age-grades are democratic and are incompatible with any system of centralized and individual authority. This accounts for the absence of age-grades in Bantu societies generally, with the exception of a few Bantu tribes of the eastern group, such as the Akikuyu, Akamba, Giriama and Chaga, who have been considerably influenced by neighbouring Hamites and have a culture which is no longer characteristically Bantu. Similarly, on the west coast of Africa we find a system analogous to age-grades among the Kru, where secret societies are almost negligible and are subordinate to the Sedibo class of age-grades, which comprises the tribal legislature and executive.

The age-grade is the distinctive feature of Hamitic culture and is found in all the tribes of East Africa which belong to the Hamitic or Nilo-Hamitic groups, including the Nilotic Lango. The Galla, with their very complex system, are the centre and source of this culture, and from them it has permeated all the Nilo-Hamitic tribes which cluster round them, the Masai and the Nandi, the Topotha, the Turkana and the Didinga.

There are naturally modifications and variations in the system adapted to the cultural requirements of each tribe, but the essentials are basically the same. At the puberty rites (which recur at regular intervals) a group of boys is initiated and they are thus aggregated into tribal, as opposed to family and clan, life. Henceforth they are no longer classed with the women but find themselves in a group of coevals, with a variety of life-long privileges and obligations towards each other. Hospitality within the age-group is compulsory, and at a later stage, when the members are permitted to marry, this often includes access to the wives of age-mates. The group on the formal side is distinguished by a variety of emblems, such as shield designs, bodily markings and ornaments, and a special name assumed jointly and individually at initiation by every member of the group and retained throughout life. Promotion to higher degrees of the system is automatic after a given number of years, and each degree has its own special functions, appropriate ceremonials and emblems, and often a particular diet and distinctive tabus; the warrior degree, for instance, being generally prohibited smoking, beer and marriage. The final degree usually enables the group-members to retire from the active life of the tribe to the more passive rôle of an elder.

The essence of the system is the corporate unity of the group, which moves from degree to degree as a single entity. This unity

makes the group so significant an element in tribal culture. At the puberty schools and at subsequent initiations on promotion to higher degrees the age-groups receive a systematic education which, as among the Galla, may extend over 32 years. Candidates are instructed in the duties of citizenship, in tribal history and tradition, ethics, the law, hunting, war, religion, husbandry, medicine, sex, in short, in every aspect of individual and communal life. They are disciplined by hardships and privations and trained to endure all manner of physical discomforts and dangers, in order to be the better able to perform the rôle traditionally allotted to the group at each degree in its initiation. Among the Galla the system provides for the government of the country by each group in turn during its last eight years of active existence. The Masai and the majority of kindred tribes use the system for military and governmental purposes, and the Lango, thanks to a changed environment, have endowed their age-grade system with functions which are almost exclusively religious. Finally, the system as a whole makes for greater tribal unity by cutting across the narrow limits of the family and the clan, by giving every individual an interest in tribal, rather than parochial, concerns, and by making every individual feel that with his group he is for the time the repository of tradition and the custodian of his tribe, both heir to the past and the pledge of posterity.

AGELADAS or (as the name is spelt in an inscription) **HAGELIDAS**, a great Argive sculptor who flourished in the latter part of the 6th and the early part of the 5th century B.C. Ageladas was said to have been the teacher of Myron, Pheidias, and Polycleitus; this tradition is a testimony to his wide fame, though historically doubtful.

AGEMA, the name of the bodyguard of Alexander of Macedonia. It was drawn from the distinguished corps of "shield bearers" or esquires (*ὑπασπισται*). While in Bactria, Alexander reorganized the agema and included some Persians.

AGEN, south-west France, capital of the department of Lot-et-Garonne, 84m. S.E. of Bordeaux by the Southern railway. Pop.

THE CATHEDRAL OF ST. CAPRAIS, AGEN, DATING FROM THE 12TH CENTURY, IS MODERN COMPARED WITH THE TOWN ITSELF WHICH WAS A CELTIC STRONGHOLD AND CONSIDERED OLD IN ROMAN TIMES

(1926) 19,619. It is skirted on the west by the Garonne, here crossed by a stone bridge and by a canal-bridge.

Agen (*Aginnum*) was the capital of the Nitiobroges, and extensive Roman ruins have been discovered. Later it was the capital of the Agenais. Its bishopric was founded in the 4th century. Agen frequently changed hands during the Albigensian wars, and at their close a tribunal of inquisition was established here. In the religious wars of the 16th century Agen took the Catholic side and joined the League in 1589. The cathedral of St. Caprais has an apse of the 12th century and three apse-chapels: the rest

dates from the 12th–16th centuries, the tower flanking the south façade is modern. The church of the Jacobins is a 13th century brick building. The prefecture (18th century) was once the bishop's palace. The *hôtel de ville* occupies the former *Hôtel du Presidial*, an obsolete tribunal, and contains the municipal library. Two houses of the 16th century, the *Hôtel d'Estrades* and the *Hôtel de Vaux*, are used as the museum. Through its excellent water communication, Agen affords an outlet for the agricultural produce of a rich district, and forms an *entrepôt* between Bordeaux and Toulouse, dealing in poultry, prunes (*pruneaux d'Agen*), and other fruit, wine, vegetables and cattle. Flour, dried plums, *pâté de foie gras* and other delicacies, manures, drugs, woven goods and tiles are made. Agen is the seat of a bishop. It has a court of appeal and a court of assizes, tribunals of first instance and of commerce and a chamber of commerce.

AGENAIS or **AGENOIS**, a former province of France. In ancient Gaul it was the country of the Nitiobroges with *Aginnum* for its capital, and in the 4th century it was the *Civitas Agennen-sium*, which formed the diocese of Agen. Having in general shared the fortunes of Aquitaine during the Merovingian and Carolingian periods, Agenais next became an hereditary countship which was purchased in 1038 by the dukes of Aquitaine. The marriage of Eleanor of Aquitaine with Henry Plantagenet in 1152 brought it under the sway of England; but when Richard I. married his sister Joan to Raymond VI., count of Toulouse, in 1196, Agenais formed part of her dowry. With the other estates of the last independent count of Toulouse it lapsed to the Crown of France in 1271, but was restored to the king of England in 1279. During the Hundred Years' War, Agenais was frequently taken and retaken, the final retreat of the English in 1453 at last leaving the king of France in peaceable possession. Thenceforth Agenais was no more than an administrative term. At the end of the *ancien régime* it formed part of the "Gouvernement" of Guienne, and at the Revolution it was incorporated in the department of Lot-et-Garonne, of which it constitutes nearly the whole. The title of count of Agenais was revived by the kings of France, and in 1789 was held by the family of the dukes of Richelieu.

AGENT: see **PRINCIPAL AND AGENT**.

AGENT-GENERAL, the term given to the representatives in England of certain of the self-governing British colonies. They are appointed, and their expenses and salaries provided, by the governments of the colonies they represent. Their duties are to look after the political and economic interests of their colonies in London, to assist in all financial and commercial matters in which their colonies may be concerned, and to make known the products of their colonies. Those colonies which are not under responsible government are represented in London by Crown agents.

AGENTS IN BUSINESS. An agent in the most general sense is any person who transacts business for another without being a direct employee, and in the majority of cases his function is to assist a principal in the purchase, sale or distribution of goods for a remuneration which usually takes the form of a commission on the price obtained. It is a term very loosely applied. Assistance may be rendered to principals irrespective of the commercial undertakings in which they are engaged. Consignment agents and credit enquiry agents are examples of this category as compared with factors or brokers who operate continuously for principals in particular industries and with manufacturers' agents who are more particularly associated with special lines of goods. There is an intermediate class of agents not directly concerned with the sale of goods and therefore not remunerated on a commission basis but who are of vital importance to the producer and manufacturer, the two most important being (a) advertising agents, whose function is to promote the commercial activity which is the beginning and the end of every undertaking, and (b) patent agents whose services are needed in most cases before manufacture can be commenced and who are also in a position to introduce their clients to the agents best qualified to market the product.

Manufacturers' Agents.—In the early stages of a manufacturing business when problems of production absorb the energies of the proprietor he is frequently glad to be relieved of all market-

ing problems by handing over the entire output to be disposed of by one or more manufacturers' agents on the commission basis which maintains this important section of the trading community. The method usually adopted is to sell by sample, the principal making arrangements for delivery and collecting accounts. But some manufacturers' agents operate on a much larger scale, especially in the textile industry, maintaining warehouses, stock rooms and administrative departments. The intimate knowledge possessed by the manufacturers' agent of the various requirements of the public is of great value to the principal; so much is this the case that the advisory services of the agent may be vital to the success of the undertaking and his influence on the policy of the business as powerful as if he were a partner. An agent of this standing is invariably consulted before new lines are introduced and he periodically brings forward suggestions calculated to increase trade which will bring him increased commission and the principal increased turnover.

Factors.—The tendency of modern business is to shorten the chain between producer and consumer, the chief forces operating being the extension of advertising in all directions, the growth of consumer co-operation and the increase in competition which leads to producer co-operation and the formation of trusts or buying groups. The effect on the manufacturers' agent is for him to accept greater personal responsibilities and virtually to take over the functions of a *factor* who, whilst his remuneration is also on a commission basis, is much more independent of his principal than is the manufacturers' agent. Invariably the factor has possession of the goods of the principal; he is generally able to get a better price and sells the goods as though they were his own leaving the buyer no clue to identity. He also frequently acts as banker for his principal owing to the necessity of his carrying a large stock for disposal in anticipation of increased demand. It is in his interests to induce the manufacturer to produce on a larger scale at a lower cost than if the production were small and this is done by his relieving the manufacturer of the necessity of recouping the expenditure of production with a quick sale. The factor is a large scale operator in a number of industries, produce, textile, grain, hide, etc., and like the manufacturers' agent is continually exposed to the pressure of the forces making for a shorter chain between producer and consumer. The tendency is for him to discharge other marketing functions, to buy up manufacturing businesses and do the work of a wholesale merchant.

Brokers.—A broker is an intermediary whose function is simply to buy or sell on behalf of a client and who does not have possession of the goods dealt with. He is present at all exchanges where produce is disposed of and business arranged. He has a specialized knowledge of particular classes of goods, their sources of supply and the avenues of marketing. His duties are of a personal character, only a small establishment being required as his business is carried on by negotiation at the exchange and in the offices of clients. In the produce market brokers are indispensable—they study the crop reports, watch cargoes, take samples, collect statistics and furnish market reports. Pressure of competition and the shortening of the producer-consumer chain impels the broker to buy and sell on his own account.

Agency as a Career.—Employment as an agent in business on a commission basis is often the last resource of a person out of employment, without any connection to assist him to secure orders and foredoomed to failure or a precarious livelihood. The ambitious youth without capital should consider agency possibilities as a stepping stone to greater remuneration as soon as he has been able to accumulate a reserve. A few years of training and experience in a merchant or factor's office will give him a knowledge of the methods of production and distribution of particular articles of manufacture until presently he has an opportunity of proving his value to his employer by suggesting new openings for agency development.

A new agency offers scope for ability and ambition to an extent presented by very few occupations. Whilst it is true that modern merchandising tends more and more towards larger units and the elimination of middlemen the increase of wealth every-

where creates new wants and an increasing market for new products. There were 30,000 applications for patents filed at the London Patent Office in the year preceding the World War and 32,000 in the year following it. The inventive genius is always bringing forward possibilities of marketing for which at first the agent is the natural instrument of development. The life is attractive to an adventurous spirit, a large circle of friends and acquaintances is formed and there is an excellent prospect of meeting the desired opportunity of entering the inner circle of the fields of manufacture and commerce. (See ADVERTISING AGENT.) (A. B. C.)

AGENTS OF PRODUCTION, in economics, a term used to describe the factors which combine in the production of wealth, as land, capital, labour (*qq.v.*) and organization. (See ENTREPRENEUR; ECONOMICS; and AGRICULTURAL ECONOMICS.)

AGESANDER, a Rhodian sculptor who is mentioned by Pliny (*Nat. Hist.* xxxvi. 37) as author (with Polydorus and Athenodorus) of the group of the Laocoön. Inscriptions found at Lindus in Rhodes date Agesander and Athenodorus to the period 42–21 B.C.

AGESILAUS II., king of Sparta, of the Eurypontid family, succeeded his step-brother Agis about 401 B.C. through the influence of Lysander. In 396 he led an expedition to Asia to secure the Greek cities against a Persian attack. Before sailing, he tried to offer a sacrifice at Aulis as Agamemnon had done before the Trojan expedition, and never forgave the Thebans for preventing him. During 396, Agesilaus made a profitable raid into Phrygia; in the following year he defeated Tissaphernes near Sardis and then ravaged the satrapy of Pharnabazus. It was said that he was planning a campaign in the interior when, to his deep regret, he was recalled to Greece owing to the war between Sparta and the combined forces of Athens, Thebes, Corinth, Argos and several minor states. After a rapid march through Thrace and Macedonia he met the confederate forces at Coronea in Boeotia and in a fierce battle was technically victorious, but the success was a barren one and he had to retire to the Peloponnese.

Agesilaus took a leading part in the Corinthian War, making successful expeditions into Corinthian territory, and capturing Lechaëum. But the destruction of a *mora* by Iphicrates neutralized these successes, and Agesilaus returned to Sparta. In 387 the Peace of Antalcidas (*q.v.*), which was warmly supported by Agesilaus, put an end to hostilities. When war broke out afresh with Thebes the king twice invaded Boeotia (378, 377) and it was on his advice that Cleombrotus marched against Thebes in 371. Cleombrotus was defeated at Leuctra and the Spartan supremacy overthrown. In 370 Agesilaus tried to restore Spartan prestige by invading Mantinea territory and his heroism saved Sparta when Epaminondas penetrated Laconia that same year, and again in 362 when he all but succeeded in seizing the city. Sparta stood aloof from the general peace of 362 hoping to recover her supremacy. In order to gain money for the war Agesilaus had supported the revolted satraps; in 361 he went to Egypt at the head of a mercenary force to aid Tachos against Persia, and died, at the age of 84, on his way home.

Agesilaus was a small man, somewhat lame from birth. He was a successful leader in guerilla warfare, alert and quick, yet cautious, and his bravery was unquestioned. He lived in the most frugal style and enriched the state and his friends with the spoils of his campaigns, returning himself as poor as he had set forth. He was sincerely patriotic; but the worst trait in his character was his implacable hatred of Thebes, which led to the battle of Leuctra and Sparta's fall from supremacy.

See lives of Agesilaus by Xenophon (the panegyric of a friend), Cornelius Nepos and Plutarch; Xenophon's *Hellenica* and Diodorus xiv., xv. Among modern authorities, besides the general histories of Greece, J. C. F. Manso, *Sparta* (1800–05) iii. 39 ff.; G. F. Hertzberg, *Das Leben des Königs Agesilaos II. von Sparta* (1856); Buttmann, *Agesilaus Sohn des Archidamus* (1872); C. Haupt, *Agesilaus in Asien* (1874); E. von Stern, *Geschichte der spartanischen und thebanischen Hegemonie* (1884).

AGGLOMERATE, in geology, the name applied to the coarse, fragmental accumulations that accompany explosive erup-

tions (*see* VOLCANO). The material may consist of blocks of lava, or of fragments of rock torn off from the sides of the volcanic pipe, or of both. An agglomerate differs only from a volcanic ash in the larger size of the fragments, which are usually sharply angular.

AGGLUTINATION, a term used technically in philology for the method of word-formation by which two significant words or roots are joined together in a single word to express a combination of the two meanings each of which retains its force (Lat. *ad* and *glutinare*, lit. to fasten together with glue). This juxtaposition or conjoining of roots is characteristic of languages such as the Turkish and Japanese, which are therefore known as agglutinative, as opposed to others, known generically as inflexional, in which differences of termination or combinations in which all separate identity disappears are predominant.

The term was also formerly used by associationist philosophers for those mental associations which were regarded as peculiarly close. W. Wundt applies this term to those simplest cases of apperceptive synthesis in which the simpler ideas composing the complex idea retain their independence—as, for instance, in the idea expressed by “church-steeple.”

AGGRAVATION (Lat. *ad*, “increasing,” *gravis*, “heavy”), the making anything graver or more serious; also used as synonymous with “irritation.” In the canon law, “aggravation” was a form of ecclesiastical censure, threatening excommunication after three disregarded admonitions.

AGGREGATE, a term used in building and construction to designate the material with which cement, lime, gypsum or other adhesive material, such as bitumen, is mixed to form a concrete or mortar (*q.v.*). The most common aggregates are sand, crushed or broken stone, gravel or pebbles, broken blast-furnace slag, boiler ashes or clinker, burned shale and burned clay. The purpose of the aggregate is to provide volume, freedom from change in volume, and resistance to wear or erosion and other desired physical properties, in the finished product.

Aggregates are divided into two general classes commonly known as fine aggregate and coarse aggregate. The fine aggregate is generally sand, crushed stone or crushed slag screenings; the coarse aggregate is gravel (pebbles), fragments of broken stone, slag and the other substances above mentioned. The dividing line between fine and coarse aggregate is usually a $\frac{1}{2}$ in. screen opening, sometimes a $\frac{3}{4}$ in. opening. Aggregates are mixed with the cement or binding material in proportions varying from one part of cementing material to one part of fine aggregate for a “rich” mortar to one part of cement to nine or ten parts of mixed fine and coarse aggregates for a “lean” concrete. The theory upon which such mixtures are proportioned is that there shall be sufficient cementing material to coat all of the particles in the fine aggregate, and that there shall be sufficient mortar so produced to fill all the voids in the coarse aggregate. The ideal concrete would consist of closely packed fragments of crushed stone, slag or pebbles in which all the fragments are coated with mortar, and all the voids between the coarser fragments filled with mortar. Under actual conditions in construction work there is practically always an excess of mortar.

Nearly all natural sands require washing or rinsing to remove loam, clay, organic material, etc. A gradual variation in size from about 50 mesh (50 openings per linear inch) to $\frac{1}{2}$ in. mesh is desirable for the strongest mortar or concrete. The preparation of commercial fine aggregate therefore often requires artificial grading or mixing of the various sizes. This is usually accomplished by hydraulic separation of the undesirable fine sizes, which usually are in excess. For coarse aggregate any hard, tough, durable rock may be crushed, screened and graded. The common commercial sizes vary from $\frac{1}{4}$ in. to $3\frac{1}{2}$ in. in largest dimension. The most desirable rocks for general construction purposes are basalt, commonly called trap, and fairly pure limestone. Such rocks are not only durable but fire-resisting, which is important in building work. Common siliceous rocks, particularly flint and many granites, expand sharply at moderately high temperatures and tend to destroy the concrete of which they form the aggregate.

In this age of concrete construction and road building the busi-

ness of supplying aggregates for construction work has grown to large proportions. In the United States alone production amounts to approximately 300,000,000 tons per annum, valued roughly at \$300,000,000, requiring an investment of about \$500,000,000 in washing, screening and crushing equipment and accessory machinery for mining and conveying the raw and finished materials. (N. C. R.)

AGGREGATES, THEORY OF. An *aggregate* may be defined, for the moment, as a collection of elements of some kind or other which is subjected to laws of operation and, on occasion, provided with a structure in such a way as to make it capable of being used to facilitate the arguments and calculations of mathematical analysis. From the point of view of pure philosophy such collections are of considerable interest in themselves and there is an extensive subject, which may be called for purposes of reference the theory of classes, which has grown up around them. This theory involves, as might be expected, considerable difficulties of a somewhat metaphysical nature and is in parts highly controversial. It is, however, possible to isolate from the rest of the theory a part which is of much practical value and almost completely free from controversy. This is the theory of aggregates. It concerns classes considered not as entities to be subjected to logical scrutiny and philosophical analysis but simply as symbols of a certain kind which are used to facilitate mathematical calculations in much the same way that numbers are used. The progress that has been made in some branches of mathematics since the introduction in the subject of the theory of aggregates is very striking.

Preliminary Notions.—It will be assumed that there is given a set of elements of some kind or other each of which can be distinguished from all the others and so may be indicated by an appropriately attached name. This set is described as the *field of operations* and the individual constituents which it contains are its *elements*. Specified elements are conveniently denoted by letters *a, b, c, ...* and unspecified elements by letters *x, y, z, ...*. There are, naturally, a great many fields of operations available. It is supposed that a particular one is selected and the subsequent theory is then relative to this field. The theory of classes, of course, has to take into account all possible fields of operations. The theory of aggregates is at most concerned with the realization of a single field of operations which shall satisfy the conditions which may at the time be imposed. The question of realizing the field of operations is almost the only part of the subject which is controversial.

Aggregates are, roughly speaking, collections of elements of the field of operations. This definition is, however, subject to the criticism that it is not very precise. Moreover, the idea of a collection involves certain metaphysical difficulties which, although some of them have been known for several thousands of years, have not been completely resolved. An alternative definition has therefore been adopted by some authorities. Nothing is said about the nature of aggregates but instead their use is defined. Aggregates are taken to be symbols the sentences containing which are interpreted by given conventions in such a way that the resulting formal laws are, up to a point, identical with those which would result from the application of the rough definition originally given. The requirements of mathematics are simply that the conventions used should be consistent. Experience seems to show that this is the case. The requirements of the mathematician are that the conventions should be easily applied. These are met by treating aggregates as though there were actual collections. Experience again shows that this procedure, if certain quite simple safeguards are employed, never leads to error. Specified aggregates may be denoted by letters *A, B, C, ...* and unspecified aggregates by letters *X, Y, Z, ...*.

The Relations ϵ and ω .—Between any element *x* of the field of operations and any given aggregate *A* one or other of two mutually exclusive relations must hold. Either *x* belongs to the aggregate, in a sense that will presently be made precise, or *x* is excluded by the aggregate. In the first case $x \epsilon A$ is written and in the second $x \omega A$. The elements which belong to *A* are described as its *members* and of them *A* is said to be *composed*.

The aggregate of which the elements which do not belong to A are the members is the *complement* of A . An interchange of ϵ and ω plainly interchanges an aggregate and its complement.

Propositional Forms.—A sentence like " a is blue" expresses a property of the element a . On the other hand a form of words and symbols like " x is blue," where x denotes an unspecified element of the field of operations, expresses nothing. It may be described as a *propositional form*. When the variable x which it contains is replaced by a name it becomes a proposition. Certain forms of words and symbols which have the appearance of propositional forms can be shown to be incapable of yielding propositions when treated in the above way. What results when the name is substituted is necessarily a meaningless array of words. The convention is therefore made that only propositional forms that are significant over the field of operations are taken into consideration in the theory of aggregates associated with any given field of operations.

The Fundamental Convention.—It is assumed that to each significant propositional form there corresponds a definite aggregate. This is described as the aggregate *determined* by the form. If the form is denoted by $f(x)$ the corresponding aggregate is denoted by $[f(x)]$.

The main convention governing the use of aggregates is that sentences involving $[f(x)]$ are to have the same meaning as corresponding sentences involving $f(x)$. Thus, to take a rough example, if A is the aggregate $[x \text{ is blue}]$ then " A is extensive" is taken to mean " x is blue' is often true." More precise examples are: " $a \in [f(x)]$ " means " $f(a)$ is true" and " $a \omega [f(x)]$ " means " $f(a)$ is false." It is possible to interchange the conventions involving ϵ and ω without causing any alteration in the formulae, provided that certain simple precautions are taken. In this way each formula can be made to yield two propositions. For this reason it is convenient, at any rate for mathematical purposes, to keep the notion of an aggregate distinct from that of a propositional form.

Null Aggregates.—An aggregate determined by a propositional form which never reduces to a true proposition, no matter what name is substituted for its variable, is described as *null*. A null aggregate is denoted by the symbol \circ . Null aggregates have formal properties closely resembling those of the number \circ . The complement of a null aggregate is the aggregate consisting of all the elements of the field of operations.

Arithmetical Theory.—Between any two aggregates operations similar to those of arithmetic may be defined. Thus:—

$$\begin{aligned} A+B &= [x \in A \text{ or } x \in B], \\ AB &= [x \in A \text{ and } x \in B], \\ A-B &= [x \in A \text{ and } x \omega B]. \end{aligned}$$

The addition or multiplication of any number of aggregates presents no difficulty. In this respect the theory of aggregates is considerably easier than the theory of numbers. Operations involving limits can also be defined. Calculations in the arithmetical theory are not much different from those in the arithmetic of numbers. It is often found that the results of extremely elementary calculations involving aggregates have an interpretation which sheds considerable light on comparatively difficult problems in other branches of mathematics.

Geometrical Theory.—A completely different but equally useful theory results when the aggregates considered are endowed with a structure in some way. Between any two points of a given aggregate, for instance, a distance may be defined. Any aggregate which has been given a structure is described as a *space*. A considerable variety of spaces is known and their consideration provides much information as to the nature of the more familiar spaces, such as the Euclidean spaces.

Application to the Theory of Functions.—There are many problems in the theory of functions (*q.v.*) which have been solved either wholly or in part by means of the theory of aggregates. This is in measure due to the intrinsic power of the theory and also to the concise and expressive way in which the theory allows the formulation of ideas. A notable advance is due to the fact that numerical functions can be defined by means of a table of

aggregates. In order to know a function $\phi(x)$ it is sufficient to know the aggregates $[\phi(x) > p]$ for only the rational values of p , whereas in the ordinary way it is necessary to know $\phi(x)$ for all values, irrational as well as rational of x .

See F. Hausdorff, *Mengenlehre* (1927, bibl.); C. J. de la Vallée Poussin, *Intégrales de Lebesgue, fonctions d'ensemble, classes de Baire* (1916). Hausdorff's work provides an unusually interesting general introduction to the subject. The reader already familiar with the theory of functions of a real variable will find some valuable applications of the theory of aggregates in the tract by de la Vallée Poussin. (S. Po.)

AGGREGATION, in physics, a collective term for the forms or states in which matter exists. Three primary "states of aggregation" are recognized—gaseous, liquid and solid. Generally, if a solid be heated to a certain temperature, it melts or fuses, assuming the liquid condition (*see* FUSION); if the heating be continued the liquid boils, and becomes a vapour (*see* VAPORIZATION). On the other hand, if a gas be sufficiently cooled and compressed, it liquefies; this transition is treated theoretically in the article CONDENSATION OF GASES, and experimentally in the article LIQUID GASES.

AGGTELEK, a village in northern Hungary in that portion of the county of Gömör that remains within Hungarian rule. Although small (pop. 555) it is world-renowned for its remarkable limestone grotto, the Aggtelek or Baradla cavern, one of the largest of its kind in Europe. It is composed of a labyrinth of passages and halls of various sizes, the total length including its ramifications exceeding 5 miles. A stream traverses the caves, which are rich in fantastic stalactite forms.

AGINCOURT (AZINCOURT), a village of northern France in the department of Pas de Calais, 14m. N.W. of St. Pol by road, famous on account of the victory, on Oct. 25, 1415, of Henry V. of England over the French. The battle was fought in the defile formed by the wood of Agincourt and that of Tramecourt, at the northern exit of which the army under d'Albret, constable of France, had placed itself so as to bar the way against the English forces which, after the capture of Harfleur, had set out to march through Picardy to Calais. Torrential rains hindered the English in crossing the Somme, and the delay allowed the French to concentrate in overwhelming numbers—d'Albret, indeed, refused to avail himself of the offer of 6,000 crossbowmen of the Paris citizen militia. Worse still, the English became so short of supplies that had the French but been content to block the path without risking an attack, hunger would have brought them the victory. The night of Oct. 24 was spent by the two armies on the ground, and the English had but little shelter from the heavy rain which fell. Early on the 25th, St. Crispin's day, Henry arrayed his little army (about 1,000 men-at-arms, 6,000 archers, and a few thousands of other foot). It is probable that the usual three "battles" were drawn up in line, each with its archers on the flanks and the dismounted men-at-arms in the centre; the archers being thrown forward in wedge-shaped salients, almost exactly as at Crécy (*q.v.*). The French, on the other hand, were drawn up in three lines, each line formed in deep masses. They were at least four times more numerous than the English, but restricted by the nature of the ground to the same narrow front 1,100 yds., they were unable to use their full weight (*cf.* Bannockburn); further, the deep mud prevented their artillery from taking part, and the crossbowmen were as usual relegated to the rear of the knights and men-at-arms. All were dismounted save a few knights and men-at-arms on the flanks, who were intended to charge the archers of the enemy. For three hours after sunrise there was no fighting; then Henry, finding that the French would not advance, moved his army farther into the defile. The archers fixed the pointed stakes, which they carried to ward off cavalry charges, and opened the engagement with flights of arrows. The chivalry of France, undisciplined and too obtuse to have assimilated the lesson of Crécy and Poitiers, was quickly stung into action, and the French mounted men charged, but their slow-moving horses made easy targets, soon shot down or driven back in confusion. The constable himself headed the leading line of dismounted men-at-arms; weighted with their armour, and sinking deep into the mud with every step, they yet reached and

engaged the English men-at-arms; for a time the fighting was severe. The thin line of the defenders was borne back and King Henry was almost beaten to the ground. But at this moment the archers, taking their hatchets, swords or other weapons, penetrated the gaps in the now disordered French, who could not move to cope with their unarmoured assailants, and were slaughtered or taken prisoners to a man. The second line of the French came on, only to be engulfed in the *mêlée*; its leaders, like those of the first line, were killed or taken, and the commanders of the third sought and found their death in the battle, while their men rode off to safety. The closing scene of the battle was a half-hearted attack made by a body of fugitives, which led merely to the slaughter of the French prisoners, which was ordered by Henry because he had not enough men both to guard them and to meet the attack. The slaughter ceased when the assailants drew off. The total loss of the English is stated at 13 men-at-arms (including the duke of York, grandson of Edward III.) and about 100 of the foot. The French lost 5,000 of noble birth killed, including the constable, three dukes, five counts and 90 barons; 1,000 more were taken prisoners, amongst them the duke of Orleans (the Charles d'Orléans of literature). The moral lesson of the battle was the incapacity of a military caste to learn from experience, and to adapt their traditions intelligently to new needs. The material lesson was that armour stultified its own purpose when it fettered mobility. The 15th-century soldier pinned his faith as obstinately on an increasing weight of armour as the 19th-century soldier on an increasing weight of numbers.

See Sir Harris Nicolas, *Battle of Agincourt*; Fortescue, *History of the British Army*, vol. i.; and H. B. George, *Battles of English History*; Oman, *History of the Art of War in the Middle Ages*, vol. ii. 379-386.

AGIO, a term used in commerce in three connections.

(a) The variations from fixed pars or rates of exchange in the currencies of different countries. For example, in most of the gold-standard countries, the standard coin is kept up to a uniform point of fineness, and so bears a constant relation to coins of other countries in a similar condition. This is what is known as the mint par of exchange. The balance of trade between the various countries is the factor determining the rate of exchange. Should the balance of trade be against England, money must be remitted to France as payment for the indebtedness. But owing to the cost for the transmission of specie there will be a demand for bills as a cheaper and more expeditious method of sending money, and it therefore will be necessary to pay a premium for it, called the agio.

(b) The term is also used to denote the difference in exchange between two currencies in the same country; where silver coinage is the legal tender, agio is sometimes allowed for payment in the more convenient form of gold, or where the paper currency of a country is reduced below the bullion which it professes to represent, an agio is payable on the appreciated currency.

(c) Lastly, in some states the coinage is so debased, owing to the wear of circulation, that the real is greatly reduced below the nominal value. Supposing that this reduction amounts to 5%, then if 100 sovereigns were offered as payment of a debt in England while such sovereigns were current there at their nominal value, they would be received as just payment; but if they were offered as payment of the same amount of debt in a foreign state, they would be received only at their intrinsic value of £95, the additional £5 constituting the agio. Where the state keeps its coinage up to a standard value no agio is required. (See **BALANCE OF TRADE**.)

AGIRA (formerly San Filippo d'Argirò), town in the province of Catania, Sicily, with a railway station $4\frac{1}{2}$ m. to the south; 35 m. W. of Catania. Pop. (1901) 17,738; (1921) 23,735 (town), 24,697 (commune). *Agyrion*, an ancient Sicel city, was ruled by tyrants, one of whom, Agyris, was contemporary of Dionysius I., and with him successfully resisted the Carthaginians in 392 B.C. Agyrion was not colonized by the Greeks until Timoleon drove out the last tyrant in 339 B.C.

AGIS, the name of four Spartan kings:

(1) Son of Eurysthenes, founder of the royal house of the Agiadae (Pausanias iii. 2. 1). His genealogy was traced back to Heracles (Herodotus vii. 204), and he belongs rather to

mythology than to history. Tradition ascribed to him the capture of Helos, and the institution of the class of serfs called *Helots*. (*q.v.*) See Ephorus ap. Strabo, viii. p. 365.

(2) AGIS I., son of Archidamus II., Eurypontid, succeeded his father, probably in 427 B.C., and from his first invasion of Attica in 425 down to the close of the Peloponnesian War was the chief leader of the Spartan operations on land. After the conclusion of the peace of Nicias (421 B.C.) he marched against the Argives in defence of Epidaurus, and after skilful manoeuvring surrounded the Argive army, and seemed to have victory within his grasp when he unaccountably concluded a four months' truce and withdrew his forces. The Spartans were indignant, and when the Argives and their allies broke the truce Agis escaped having his house razed and a fine of 100,000 drachmae imposed only by promising to atone for his error by a signal victory. This promise he fulfilled by routing the forces of the Argive confederacy at the battle of Mantinea (418). In the winter 417-416 a further expedition to Argos resulted in the destruction of the half-finished Long Walls and the capture of Hysiae. In 413, on the suggestion of Alcibiades, he fortified Decelea in Attica, where he remained directing operations until, after the battle of Aegospotami (405), he took the leading part in the blockade of Athens, which was ended in the spring of 404 by the surrender of the city. Subsequently he invaded and ravaged Elis. He fell ill on his return from Delphi, where he had gone to dedicate a tithe of the spoils, and died at Sparta, probably in 401.

Anim.* 6. (See **PELOPONNESIAN WAR**.)

(3) AGIS II., son of Archidamus III., of the Eurypontid line, succeeded his father in 338 B.C., on the very day of the battle of Chaeronea. During Alexander's Asiatic campaign he revolted against Macedonia (333 B.C.) and, with the aid of Persian money and ships and a force of 8,000 Greek mercenaries, gained considerable successes in Crete. In the Peloponnese he routed a force under Corragus and, although Athens held aloof, he was joined by Elis, Achaea (except Pellene) and Arcadia, with the exception of Megalopolis, which the allies besieged. Antipater marched rapidly to its relief at the head of a large army, and the allied force was defeated after a desperate struggle (331) and Agis was slain.

BIBLIOGRAPHY.—See Pausanias iii. 10. 5; Diodorus xvii. 48, 62, 63; Justin xii. 1; Quintus Curtius iv., 1, 39, vi., 1; Arrian, *Anabasis*, ii. 13.

(4) AGIS III., son of Eudamidas II., of the Eurypontid family, succeeded his father, probably in 245 B.C., in his 20th year, at a time when the unequal distribution of land and wealth and the diminution in the number of full citizens threatened to ruin Sparta. He determined to restore the traditional institutions of Lycurgus. Lysander as ephor proposed on behalf of Agis that all debts should be cancelled and that Laconia should be divided into 19,500 lots, of which 4,500 should be given to Spartiates, whose number was to be recruited from the best of the perioeci and foreigners, and the remaining 15,000 to perioeci who could bear arms. The abolition of debts was carried into effect, but the land distribution was put off on various pretexts by Agesilaus, the king's uncle, who wished to preserve his estates. At this point Aratus appealed to Sparta to help the Achaeans in repelling an expected Aetolian attack, and Agis was sent to the Isthmus at the head of an army. During his absence his enemies gained the upper hand, and on his return Agis, after a mock trial, was strangled in prison, his mother and grandmother sharing the same fate (241).

See Plutarch's biography. Pausanias' accounts (ii. 8. 5, vii. 7. 3, viii. 10. 5-8, 27. 13) of his attack on Megalopolis, his seizure of Pellene and his death at Mantinea fighting against the Arcadians, Achaeans and Sicyonians are without foundation (J. C. F. Manso, *Sparta*, iii. 2. 123-127, 1800-05). See also Manso, *op. cit.* iii. I. 276-302; B. Niese, *Geschichte der griechischen und makedonischen Staaten*, ii. 299-303 (1884).

AGISTMENT. To "agist" is, in law, to take cattle to graze, for a remuneration. The word is derived through O. Fr. from Lat. *iacere*, to lie. "Agistment," in the first instance, referred

more particularly to the proceeds of pasturage in the king's forests, but now means either (a) the contract for taking in and feeding horses or other cattle on pasture-land, for the consideration of a weekly payment of money, or (b) the profit derived from such pasturing. Agistment is a contract of bailment, and the bailee is bound to take reasonable care of the animals entrusted to him; he is responsible for damages and injury which result from ordinary casualties, if it be proved that such might have been prevented by the exercise of reasonable care.

There is no lien on the cattle for the price of the agistment, unless by express agreement. Under the Agricultural Holdings Act, 1883, agisted cattle cannot be distrained on for rent if there be other sufficient distress to be found, and if such other distress be not found, and the cattle be distrained, the owner may redeem them on paying the price of their agistment.

AGITATION, THERMAL, the motion of the molecules, within a body, which they possess by virtue of their absolute temperature (*q.v.*). (See KINETIC THEORY OF MATTER; THERMODYNAMICS.)

AGITATO (Ital.), a musical term implying that the composition or passage so marked is to be played in a restless, agitated manner, a rapid *tempo* being usually indicated at the same time by the accompanying time-direction, *e.g.*, *presto agitato*.

AGITATORS or **ADJUTATORS**, the name given to representatives elected in 1647 by the different regiments of the English parliamentary army. Early in 1647 the Long Parliament wished either to disband many of the regiments or to send them to Ireland. The soldiers, whose pay was largely in arrear, refused to accept either alternative, and eight of the cavalry regiments elected agitators, called at first commissioners, who laid their grievances before the three generals, and whose letter was read in the House of Commons on April 30, 1647. The other regiments followed the example of the cavalry, and after a temporary conciliation Parliament decided to disband the army on June 1. The agitators determined to resist; a mutiny occurred in one regiment and the attempt at disbandment collapsed. There followed the seizure of the king by Cornet Joyce, Cromwell's definite adherence to the policy of the army, the signing of the manifestos, a *Humble Representation* and a *Solemn Engagement*, and the establishment of the army council composed of officers and agitators. The agitators finally demanded a march towards London and the "purging" of the House of Commons. Subsequent events are part of the general history of England. Gradually the agitators ceased to exist, but many of their ideas were adopted by the Levellers (*q.v.*), who may perhaps be regarded as their successors.

See S. R. Gardiner, *History of the Great Civil War*, vols. iii. and iv. (1905).

AGNANO, LAGO DI, a crater lake, 5 m. W. of Naples, Italy; 4 m. in circumference, not mentioned in antiquity, probably formed in the Middle Ages, drained in 1866. It has a large modern thermal establishment with springs, natural sulphurous vapour baths and a grotto with constant exudation of warm carbonic-acid gas from the floor. There are extensive Roman remains (V. Macchioro, *Monumenti dei Lincei*, xxi. p. 225. sqq., 1911). On the north side of the crater is a racecourse.

AGNATES, in Roman law, persons related through males only, as opposed to cognates. Agnation was founded on the idea of the family held together by the *patria potestas*; *cognatio* involves simply the modern idea of kindred.

AGNES, SAINT, a virgin martyr of the Catholic Church. The legend of St. Agnes is that she was a Roman maid, by birth a Christian, who suffered martyrdom at the age of 13, during the reign of the emperor Diocletian, on Jan. 21, 304. The prefect Sempronius wished her to marry his son, and on her refusal condemned her to be outraged before her execution, but her honour was miraculously preserved. When led out to die she was tied to a stake, but the faggots would not burn, whereupon the officer in charge of the troops drew his sword and struck off her head. St. Agnes is the patron saint of young girls, who, in rural districts, formerly indulged in all sorts of quaint country magic on St. Agnes' Eve (Jan. 20-21) with a view to discovering their future husbands. This superstition has been immortalized in

Keats's poem, "The Eve of St. Agnes." St. Agnes's bones are supposed to rest in the church of her name at Rome, originally built by Constantine and repaired by Pope Honorius in the 7th century. Here on her festival (Jan. 21) two lambs are specially blessed after pontifical high mass, and their wool is later woven into pallia.

AGNESI, MARIA GAETANA (1718-1799), Italian mathematician, linguist and philosopher, was born at Milan on May 16, 1718. She was an extremely precocious child. Her father was a professor of mathematics. Maria was only fourteen when she began to read a series of theses on philosophical questions to the learned men of Bologna who met regularly in her father's house (see Brosse, *Lettres sur l'Italie*). Her family resisted her early desire to enter a convent, but from her 20th year onward she lived in complete seclusion at home, devoting herself to the study of mathematics. When her father fell ill in 1752 Pope Benedict XIV. appointed her to his chair in the university. But on his death in 1754 she became directress of the Hospice Trivulzio of the Blue Nuns at Milan, and eventually joined the sisterhood. She died on Jan. 9, 1799. Her principal work is *Istituzioni analitiche ad uso della gioventù italiana* (2 vols., Milan 1748; French trans. of vol. i., Paris 1775; complete Eng. trans. by John Colson, 1801).

Her sister, **MARIA TERESA AGNESI** (1724-80), composed several cantatas, two pianoforte concertos and five operas.

BIBLIOGRAPHY.—See Antonio Francesco Frisi, *Éloge historique de Mademoiselle Agnesi*, translated by Boulard (Paris, 1807); Miles-Mojon, *Vita di M. G. Agnesi* (Milan, 1836); J. Boyer, "La Mathématicienne Agnesi," in the *Revue Catholique des revues françaises et étrangères* (Paris, 1897).

AGNES OF MERAN (d. 1201), queen of France, was the daughter of Bertold IV., duke of Meran in Tirol. She is called Marie by some of the chroniclers. In June 1196 she married Philip II., king of France, who had repudiated Ingeborg of Denmark in 1193. The pope espoused the cause of Ingeborg; but Philip did not submit until 1200, when, interdict having been added to excommunication, he consented to a separation from Agnes. She died in July of the next year.

See the notes of Robert Davidsohn in *Philipp. II. August von Frankreich und Ingeborg* (Stuttgart, 1888). A genealogical notice is furnished by the *Chronicon* of the monk Alberic (Aubry) of Trois-Fontaines (Albericus Trium Fontium) in Pertz, *Scriptores*, vol. xxiii.

AGNEW, DAVID HAYES (1818-1892), American surgeon, was born in Lancaster county, Pa., on Nov. 24, 1818. He graduated from the medical department of the University of Pennsylvania in 1838, and a few years later set up in practice at Philadelphia and became a lecturer at the Philadelphia School of Anatomy. He was appointed surgeon at the Philadelphia hospital in 1854 and was the founder of its pathological museum. For 26 years (1863-89) he was connected with the medical faculty of the University of Pennsylvania, being elected professor of operative surgery in 1870 and professor of the principles and practice of surgery in 1871. From 1865 to 1884—except for a brief interval—he was a surgeon at the Pennsylvania hospital. During the American Civil War he was consulting surgeon in the Mower Army hospital, near Philadelphia, and acquired considerable reputation for his operations in cases of gun-shot wounds. He attended as operating surgeon when President Garfield was fatally wounded by the bullet of an assassin in 1881. He was the author of several works, the most important being *The Principles and Practice of Surgery* (1878-83). He died in Philadelphia on March 22, 1892.

AGNI, the fire god of the Hindus, second only to Indra in the Vedic mythology of India. He is invoked as "priest of sacrifice" in the first verse of the *Rig-Veda*, and, as messenger, between gods and men, sacrifices to him are upborne to the deities. On earth his parents are the two sticks of the fire drill, and every day he is reborn an immortal, living among men and supreme director of religious rites and duties. His form is however three-fold, fire on earth, lightning and the sun, and in art he is depicted as ruddy, with two faces, beneficent and malignant, three-legged (as in the fylfot, with seven arms). Later he was identified with Rūdra (*q.v.*). In modern India he has no professed sect, but is invoked in many ceremonies, and specially

affected by Agnihotri Brahmins who perform the "fire sacrifice" (*agnihotra*).

See A. A. Macdonell, *Vedic Mythology*, and F. Washburn Hopkins, *Epic Mythology* (1897 and 1915); J. N. Farquhar, *Outlines of the Religious Literature of India* and Mrs. Sinclair Stevenson, *Rites of the Twice-born* (1920).

AGNI, inhabitants of the Cold Coast and the French Ivory Coast between the Fanti territory and the Comoé river, south of the Abbron (*q.v.*) people. They are of the same origin and have the same physical, social and linguistic characteristics as the Baule.

AGNOETAE, a minority of adherents to the Monophysite movement who (contrary to the general tendency of that form of Christology) maintained that Christ as man was ignorant of many things (Mark xiii. 32; Luke ii. 25) (Gr. *ἀγνοέω*, "be ignorant of"). The doctrine was condemned by Gregory the Great. (See **MONOPHYSITES**.)

AGNOIOLOGY (the theory of ignorance). The term was used by J. F. Ferrier (*Institutes of Metaphysics*, 1854) as a set-off to *Epistemology* (theory of knowledge). The theory was intended to counter the sceptical contention that Absolute Being may be beyond human knowledge, that the human mind may be condemned to remain ignorant of it. Ferrier's contention is that man cannot be said to be ignorant of what cannot be known; he can only be said to be ignorant when he does not know what can be known. On such lines Ferrier concludes that, since Absolute Being must either be something that we know or something that we are ignorant of, it cannot be subject only or object only but a synthesis of both.

AGNOSTICISM. Whereas scepticism, as a technical term in philosophy, denotes varying degrees of doubt as to whether some or all of the psychological processes, purporting to yield knowledge, really do so, agnosticism rather asserts that, of certain kinds of objects or facts, we possess assured knowledge, while as to certain other kinds of alleged existents we have, and can have, none. The kinds of alleged objects, knowledge as to which the agnostic believes to be impossible, are such as are the primary concern of metaphysics and theology: God, the soul and its immortality, and—more generally speaking—the ultimate realities of which phenomenal things, such as the sciences study, are appearances. Of these phenomenal things, we have ever-increasing and irrefragable knowledge; as to the things *per se*, the ontal or noumenal existents, of which the "things" of common sense and science are the knowable shadows or appearances, we can never have knowledge pure and subjectively undefined. If we know that they are, we cannot know *what* they are; if we can assert their existence, we are ignorant as to their essence.

The name "agnosticism" was coined by Huxley about 1870 to distinguish this philosophical attitude from others, but the attitude had been professed before. It is, in fact, one of the issues of Kant's imposing theory of knowledge, and it had become, through the investigations of Sir W. Hamilton, Dean Mansel and Herbert Spencer, more sharply defined and more elaborately developed. Huxley, who was perhaps its most widely-known champion in the latter half of the 19th century, gave definiteness to its exposition by forcibly contrasting metaphysical and theological belief with scientific knowledge. We can now see that the controversial issue was confused, through failure at that time to realize that the word "knowledge" denotes not one sole psychological process and product, but several that are distinguishable; and also that what is called scientific knowledge is not quite so simple in its psychological structure, nor so logically "positive" in its nature, as the philosophically-inclined representatives of science in Huxley's day were wont to assume. The positivists who were led by the progress and prestige of physical science to regard science as constituted entirely by sense-data, linked together solely by relations such as could be read-off with the inevitableness and self-evidence of similarity, temporal sequence, etc., overlooked the fact, which had been clearly discerned by Hume, that we have no *logical* right to pass from our sporadic and evanescent sense-data, which yield evidence only as to here and now, to belief in a stable system of permanent things governed by law. The right is not a matter of logical neces-

sitation but of psychological inevitableness; not of logical certification but of pragmatic verification; not of logical certainty but of personal certitude or sanguine confidence. Thus science is not knowledge, in the strict sense of reading-off, supplemented by logical inference. Such knowledge, and indeed the phenomenal objects about which it claims to know, are constituted such by suppositions that, in the first instance, are read *into* the data. Thus "knowing" means, in science of the actual, something different both from the immediate "acquaintance" of sense-perception and from the "truth" that is yielded by pure sciences, such as mathematics, whose "objects" are ideas—such as the line without breadth—and not actual things. This is also the doctrine of Kant. But Kant held that the reading-in that is involved in scientific knowledge is *a priori* necessary, so that such knowledge is knowledge in the strictest sense; whereas the reading-in that is involved in metaphysics and theology is but tentative and humanly expedient. This hard line between what Kant called understanding and reason—we might say between knowledge and mere belief—is now seen to be psychologically arbitrary, not so hard as he thought, and indeed to be drawn at the wrong place. Hence the rigid separation, once wont to be alleged between science and philosophy, and, on the strength of which, metaphysics and theology were disparaged, is no longer possible. The agnostic can no longer have that certainty as to the foundations of his science, in virtue of which he asserted nescience as to the non-phenomenal. The difference between the knowledge which he asserted and the knowledge which he disclaimed is one of degree of verifiability, not of kind or of intrinsic constitution.

But agnosticism, which issues out of Kant's phenomenalism, is imbued with consequences of what may be said to be another oversight of Kant, perhaps still more significant in import. Kant tried to work with the supposition that, though facts compel us to assert the existence of things *per se*, we can know no more about them. His doctrine implies that we can only know the phenomenal. This is the teaching that was developed by Hamilton into the dogmas that we can have no knowledge of the absolute or of ultimate reality, and no absolute or pure knowledge of anything: all knowledge is but relative. As to its Kantian foundation, it seems obvious that if we must posit things *per se*, in order to account for our sense-data being forthcoming, so must relations between things *per se* be posited to account for the stable connections between sense-data, which science elaborates into laws of nature. Indeed, unless we create most of our data out of nothing or out of our subjective states, etc., there must be structure and detail in the ontal corresponding to that which we observe in the phenomenal. Appearance cannot be appearance of nothing. Hence, instead of the Kantian formula, that we only know phenomena, it is more correct to say that we know the noumenal through the phenomenal. Thus there is not absolute nescience as to the noumenal, as agnosticism would assert. The most that can be urged is that we do not see the noumenal, so to say, through plate glass, but through the irremovable spectacles of the mind, which make a difference to the noumenal object or phenomenalize it. It is at this point that Hamilton's doctrine of the relativity of knowledge applies. He would regard phenomenal knowledge of the noumenal as not knowledge at all, because, in having it, we are not identical with the objects known nor become acquainted with them as they are in themselves. Our knowledge falls short of the ideal standard, in that it is impure—which is what he chiefly means by "relative." But it may be doubted whether knowledge suffers in value on that account. There is no reason to assume that, in imaging the real, the phenomenon veils it or caricatures and misrepresents it; it may reveal it, and reveal its significance just as effectually as would seeing face to face. What matters is that phenomenal knowledge should be *relevant* to reality, not that it should mirror its naked structure. An ordnance map serves all purposes of the tourist, though it may not mirror the coloured landscape or the geological formations of the district; it is relevant, if but appearance and not a copy. There is point-to-point correspondence between the lines and contours on the map and the streams, roads, gradients, etc., of the country which

it represents. Our phenomenal knowledge may bear—nay, must bear—much the same sort of relation as this to the realities which manifest themselves in and through the sensible and phenomenal. It enables us to “find our way about” our world, to be on terms of understanding with it and it may minister as much to spiritual wisdom as to practical prudence; for all that it is but phenomenal. That “we see through a glass, darkly” may be our lot here; but it does not follow that we are wholly blind as to all that concerns our souls’ health. Thus it would appear that agnosticism is superfluously modest. Its demurrer to the philosopher’s claim that knowledge as to ultimate reality in general is inaccessible is not sustained. If it would refuse the name of knowledge to such cognition it would seem to be cherishing a conception of knowledge to which no actually forthcoming “knowing” corresponds. For science itself, wont to be taken as the paradigm of knowledge, is at bottom interpretative, constructive, ejective and partly symbolical. Its inductive method involves faith, for which there is reasonable, but not logical, justification. And knowledge as to the objects with which metaphysics and theology are concerned, is but a further extension of the same method and the same sustaining faith as science uses, applied to such facts as evince meaning or purpose and value or significance, as well as to those which yield laws as to physical structure and connections.

BIBLIOGRAPHY.—J. Ward, *Naturalism and Agnosticism*; R. Flint, *Agnosticism* (1903). (F. R. T.)

AGNUS DEI, the figure of a lamb bearing a cross, symbolizing the Saviour as the “Lamb of God.” The name is especially given in the Roman Church to waxen discs impressed with this figure and blessed by the pope. When first mentioned (c. 820) they were made of the remnants of the preceding year’s paschal candle. In modern times they are blessed on Easter Wednesday and distributed on the following Saturday, only in the first year of each pontificate and every seventh year after.

Agnus Dei is also the name for the invocation (based on John i. 29) *Agnus Dei, qui tollis peccata mundi, miserere nobis*, which appears to have been introduced into the Mass by Pope Sergius I. (687–701). It is there repeated thrice (the third time with *dona nobis pacem for miserere nobis*) between the Lord’s Prayer and the communion; it is also appended to many of the litanies. The legality of its use in English, under certain conditions, in the Anglican communion service was upheld by the judgment in the Lincoln case (1890).

For the various ceremonies in the blessing of the *Agnus Dei*, see A. Vacant, *Dict. de Théologie* (cols. 605–613).

AGOBARD (c. 779–840), Carolingian prelate and reformer, became coadjutor to Leidrad, archbishop of Lyons, in 813, and on the death of the latter succeeded him in the see (816). Deposed in 835 by the council of Thionville, he made his peace with the emperor and was reinstated in 837. Agobard occupies an important place in the Carolingian renaissance. He wrote extensively not only theological works but also political pamphlets and dissertations directed against popular superstitions. He denounced the trial by ordeal of fire and water, the belief in witchcraft, and the ascription of tempests to magic, maintained the Carolingian opposition to image-worship, but carried his logic farther and opposed the adoration of the saints. In his purely theological works Agobard was strictly orthodox, except that he denied the verbal inspiration of the Scriptures. Agobard was revered as a saint in Lyons, and although his canonization is disputed his life is given by the Bollandists, *Acta Sanctorum*, Jun. ii. 748.

BIBLIOGRAPHY.—Agobard’s works were lost until 1605, when a manuscript was discovered in Lyons and published by Papirius Masson, again by Baluze in 1666. For later editions see Potthast, *Bibliotheca Historica Medii Aevi*. The life of Agobard in Ebert’s *Geschichte der Litteratur des Mittelalters* (1880), is still one of the best to consult. For further indications see A. Molinier, *Sources de l’histoire de France*.

AGONALIA, in ancient Rome, festivals celebrated on Jan. 9, Mar. 17, May 21 and Dec. 11 in each year in honour of various divinities (Ovid, *Fasti*, i., 319–332). The word is derived either from *agonia*, “a victim,” or from *agonium*, “a festival,” but there is no certainty as to the etymology of the word.

AGONOTHETES, in ancient Greece, the president or superintendent of the sacred games. At first the person who instituted the games and defrayed the expenses was the Agonothetes. But in the public games, such as the Olympic and Pythian, these superintendents represented different States, or were chosen from the people in whose country the games were celebrated; thus at the Panathenaea at Athens ten *athlothetai* were elected for four years to superintend the various contests. They were variously called “regulators,” “arbitrators,” “judges of contests,” “stewards of the games” (at Athens), “rod-bearers” (from the rod or sceptre emblematic of their authority), but their functions were generally the same.

AGONY COLUMN, a term often applied to the column in newspapers devoted to personal advertisements, such as announcements of losses or bequests. As early a date as 1800 the “agony column” was a medium also for matrimonial advertisements. It is sometimes known as the personal column.

See Alice Clay, *The Agony Column of the “Times” 1800–1870* (1881).

AGORA, originally an assembly of the people of one of the Greek city States, called by the king or other authority to receive a decree or to discuss a policy. At an early period the word was used to describe the places where these meetings were held and in historic times any open space for general meetings, either official or commercial, was termed an agora. The agora of the historic Greek city was thus similar to the Roman forum or the mediaeval English market place. As the agora was the centre of the city life, it was surrounded by, or adjacent to the most important civic buildings, the prytaneum or official residence of the general, the basilica where the court sat, the *bouleuterion* or council hall, the thesaurus or treasury and the prison. As the market place, it had ranges of sheds or colonnades for shops; frequently the colonnades were divided into parts, each named after the particular merchandise sold therein.

After the Persian wars the architectural treatment of the agora became much more monumental and lavish colonnades were frequently added to the older agorae, such as the Stoa of Attalus in the agora at Athens (between 159 and 138 B.C.). Of these later agorae many fine examples exist in various states of preservation. That at Ephesus was a square court over 500 ft. on the side, connected with additional courts containing a gorgeous nymphaeum and the lavish Roman library. At Priene the agora was traversed by streets but arranged so that through traffic was carried below on a detour. The substructures of the hillside agorae at Aegaea and Alinda still remain almost complete. In these cases the agora on a high terrace had large storage warehouses below. The great terrace wall at Alinda, with its striking rusticated masonry and large Roman arched openings, is especially impressive. Most important of all, however, is the agora at Assus, of which extensive remains still exist in a good state of preservation, with enough fragments to enable a complete and definitive restoration. This, like the two foregoing, is a hillside agora, supported on massive terrace walls. Its main architectural feature is the great two-storey portico.

The forum at Pompeii, in plan, dates probably from the time of the Greek colony. It therefore forms a connecting link between the Greek agora and the Roman forum. With its surrounding colonnade, its basilica, the city temple at one end and the civic offices at the other, it gives a perfect picture of what the typical Greek agora was like. (For the agora at Athens see **ATHENS**.)

For a general discussion, see Cornish, *Dictionary of Greek and Roman Antiquities* (1898). The typical plan given is, however, absurd through its obvious misinterpretation of a passage in Pausanias in which he refers to colonnades separated by streets. Pausanias plainly refers to streets traversing the agora and thus dividing the enclosing colonnade into separate sections. See also S. H. Bacon and Robert Koldewey, *Expedition of the Archaeological Institute of America* (investigations at Assus in 1881–83, 1902–21); Anderson and Spiers, *Architecture of Ancient Greece*, new ed. by W. B. Dinsmoor (1927).

AGORACRITUS, a Parian and Athenian sculptor of the age of Pheidias, and said to have been his favourite pupil. His most noted work was the statue at Rhamnus of Nemesis, by some

attributed to Pheidias himself. Of this statue part of the head is in the British Museum; some fragments of the reliefs which adorned the pedestal are in the museum at Athens.

AGORANOMI. Magistrates in Greece, whose duties were similar to those of the aediles of Rome. In Athens there were ten, five of whom took charge of the city and five of the Peiræus. They maintained order in the markets, tested weights and measures, collected the harbour dues, and enforced the shipping regulations.

AGORDAT, a town of Eritrea, North-east Africa, on the route between Massawa and Kassala. It is connected by a railway, 194 miles long, with Massawa, via Asmara. At Agordat (Dec. 21, 1893) Italians under Colonel Arimondi defeated the followers of the khalifa. (See ERITREA and SUDAN; *History*.)

AGOSTINO and **AGNOLO** (or **ANGELO**) **DA SIENA**, Italian architects and sculptors in the first half of the 14th century. Della Valle and other commentators deny that they were brothers. They certainly studied together under Giovanni Pisano, and in 1317 were jointly appointed architects of their native town, for which they designed the Porto Romana, the church and convent of St. Francis, and other buildings. On the recommendation of Giotto (q.v.), they executed in 1330 the tomb of Bishop Guido Tarlati in the cathedral of Arezzo, which Giotto had designed. This monument was destroyed by the French under the duke of Anjou.

AGOSTINO or **AGOSTINI** (**AUGUSTINUS**), **PAOLO** (1593–1629), Italian musician, was born at Valerano, and studied under G. B. Nanini. He succeeded Ugolini as conductor of the pope's orchestra in St. Peter's. Among his compositions is an *Agnus Dei* for eight voices, once greatly admired.

AGOULT, MARIE CATHERINE SOPHIE DE FLAVIGNY, COMTESSE D' (1805–1876), French author, whose *nom de plume* was "Daniel Stern," was born at Frankfurt-on-Main on Dec. 31, 1805. Her father was a French officer who had served in the army of the emigrant princes, and her mother was the daughter of a Frankfurt banker. She was married in 1827 to the comte Charles d'Agoult. In Paris she gathered round her a brilliant society which included Alfred de Vigny, Sainte-Beuve, Ingres, Chopin, Meyerbeer, Heine and others. She was separated from her husband, and became the mistress of Franz Liszt. During her frequent travels in Switzerland, France and Italy she made the acquaintance of George Sand, and figures in the *Lettres d'un voyageur* as "Arabella." By Liszt she had three children—a son who died young; Blandine, who married Émile Ollivier; and Cosima, who married first Hans von Bülow and later Richard Wagner. The story of her breach with Liszt is told under a very slight disguise in her novel *Néïda* (1845). On her return to Paris in 1841 she began to write for the *Presse*, and later for the *Revue des deux Mondes* and the *Revue indépendante*. Mme. d'Agoult was an ardent apostle of the ideas of '48, and from this date her *salon*, which had been literary and artistic, took on a more political tone; revolutionists of various nationalities were welcomed by her, and she had an especial friendship and sympathy for Daniele Manin. In 1857 she produced a national drama, *Jeanne d'Arc*, which was translated into Italian and presented with success at Turin. The most important section of Daniel Stern's work is her political and historical essays: *Lettres républicaines* (1848), *Esquisses morales et politiques* (1849), *Histoire de la Révolution de 1848* (1850–1853), *Histoire des commencements de la République aux Pays-Bas* (1872). Mme. d'Agoult died in Paris March 5, 1876.

See Mme. d'Agoult, *Mes Souvenirs* (1806–33), 1877; J. Mazzini, *Lettres de Joseph Mazzini à Daniel Stern* (1872); A. Pommier, *Madame la comtesse d'Agoult* (Daniel Stern), 1876; A. Cu villier Fleury, *Portraits révolutionnaires*, vol. i. (1889); A. Ungherini, "Daniel Stern" in the *Revista repubblicana* (1880, No. 9); S. Rocheblave, *Une Amitié romanesque, George Sand et Madame d'Agoult* (1895); R. Bory, *Une Retraite romantique en Suisse; Liszt et la comtesse d'Agoult* (1923), with an appendix containing letters; Daniel Oliver, *Mémoires de la comtesse d'Agoult: 1833–54* (1926).

AGOUTI or **AGUTI** (a-gōō-tě), rodent (*Dasyprocta aguti*), of the size of a rabbit, common to Trinidad and Guiana, and classed in the family *Caviidae*. Agoutis are slender-limbed animals,

with five front and three hind toes (the first front toe very minute), and short tails. The hair is coarse and rough; the colour being rufous brown. In habits agoutis are nocturnal, dwelling in forests, where they conceal themselves during the day in hollow tree-trunks, or in burrows among roots. They take readily to water and swim well. Their food comprises leaves, roots, nuts and

THE AGOUTI, COMMON IN EASTERN SOUTH AMERICA, AND DESTRUCTIVE TO SUGAR CANE AND BANANA PLANTS

other fruits. They do much harm to plantations of sugar-cane and bananas.

AGRA, the headquarters of a district and division in the United Provinces, was for long periods the capital city of India. It stands on the Jumna which, though now at this point a mere trickle in the dry season, was formerly one of the chief arteries of commerce with the rest of India and at the same time a powerful frontier defence. Of the original Agra, which apparently lay on the left bank of the river, practically no traces remain. The present city on the right bank was the creation of the Mohammedan conquerors. The earlier dynasties fluctuated between Delhi and Agra as their centre of power; but it was at Agra that Sikander Lodi (A.D. 1500) set up his court, deeming it the strategic point for holding in check his turbulent vassals to the south. In 1526 the city was captured by Baber, the Koh-i-nur diamond being part of his booty. It was here that he decided to occupy India in permanence; here also that he died. It was his grandson Akbar who began to build the present fort (still by the people called Akbarabad), ruled India from within the walls, died in it, and was buried at Sikandra a few miles beyond the city gates. Agra fell from its pride of place when Aurangzeb moved to Delhi, and was never again the seat of monarchy. In the latter half of the 18th century, it was captured successively by the Jats, the Mahrattas, the Mohammedans and Scindhia; but it was finally taken by Lord Lake in 1803. After British rule was extended to upper India, it became the capital of the North-West provinces until at the close of the Mutiny the seat of that Government was transferred to Allahabad. The city is now a busy railway and commercial centre with cotton mills, gins and presses, flour mills and an important carpet industry. There are two large colleges and several other educational institutions, including a medical school for men and women; and the establishment of a university is under contemplation. Pop. in 1921, 185,532.

Although to travellers Agra is essentially the city of the Taj, it enshrines several other magnificent specimens of Mogul architecture, each perfect of its kind. The fort, with its lofty walls of red sandstone 1½ m. in circumference, contains at least two such gems. Separated from each other by the main block of the buildings of the imperial court, stand on the north the Pearl Mosque, built by Shah Jahan, and on the south the Jahangiri Mahal or palace built by Akbar; the former unequalled for the beauty and purity of its proportions, material and constructive design in simple white marble; the latter a perfect adaptation of stately solidity and commanding symmetry of the Hindu style. If we leave the fort and cross the river, we find another gem of its kind in the tomb of Itmad-ud-Daulah, father of Jahangir's empress. Its architecture is transitional between the virile conceptions of Akbar and the poetic richness of Shah Jahan; elegant, elaborate and scholarly, it was the first triumph of marble inlaid work in direct imitation of Persian pottery decoration. Five miles from Agra is Sikandra, where Akbar was buried, though his remains were desecrated and scattered by Jat freebooters in later years. His tomb is a noble building in a noble setting, and the marble sarcophagus on its roof is strikingly impressive in its simple dignity. Far exceeding all the others in glory is the Taj, the most beautiful mausoleum in the world. It was built by Shah Jahan for his empress, who died in A.D. 1631; and from one of her titles, Taj Mahal or Crown of the Palace, it takes the name by which it is most generally known outside India. Built of pure white marble, it stands on a vast marble terrace, crowned by a great dome in the centre and smaller domes at each of its corners. From the angles of the terrace rise

four slender minarets. Subservient and supplementary to the glory of the outline is the beauty of the ornamentation. "All the spandrels of the Taj," writes Fergusson. "all the angles and more important architectural details are heightened by being inlaid with precious stones such as agates, bloodstones, jaspers and the like. These are combined in wreaths, scrolls and frets as exquisite in design as they are beautiful in colour, and relieved by the pure white marble in which they are inlaid, they form the most beautiful and precious style of ornament ever adopted in architecture."

The architect of the Taj was Ustad Isa, variously described as a Byzantine Turk, and as a Persian from Shiraz. The artificers engaged during the 17 years of its construction came from all

parts of Asia and probably included a French goldsmith, Austin de Bordeaux.

The district of Agra has an area of 1,856 sq. miles. Its general appearance is that common to the Doab, a level plain intersected by watercourses with fringes of ravines. Its general elevation is estimated at from 650 to 700 ft. above the level of the sea. The district is intersected by the Jumna, and is also watered by the Agra canal. The principal crops are millets, pulses, barley, wheat, cotton and a little indigo. The population in 1921 was 924,155.

The division of Agra has an area of 8,545 sq. miles. In 1921 the population was 4,182,825. It comprises the five districts of Aligarh, Muttra, Agra, Mainpuri and Etah.

AGRA CANAL, primarily an irrigation project opened in 1874, but widely used for navigation. It is supplied with water from the Jumna river and beginning at Okla, 10 m. below Delhi it passes through the districts of Delhi, Gurgaon, Muttra and Agra as well as the Bharatpur state. It finally joins the Banganga river about 20 m. below Agra.

AGRAM: see ZAGREB.

AGRAPHA, the name given to certain utterances ascribed, with some degree of certainty, to Jesus, which have been preserved in documents other than the Gospels, e.g., Acts xx. 35; 1 Tim. v. 18; 1 Cor. vii. 10-12, and the Logia (q.v.) discovered in 1897 and 1903 at Oxyrhynchus.

BIBLIOGRAPHY.—See A. Resch, *Agrapha* (Leipzig, 1889); J. H. Ropes, *Die Sprüche Jesu* (Leipzig, 1896); and the article "Sayings" in J. Hastings's *Dictionary of Christ and the Gospels*.

AGRARIAN LAWS, law dealing with the disposal of the public land (*ager publicus*) of ancient Rome. No gratuitous disposition of state property could be made without the consent of the people. Hence many of the ordinances affecting the

public land were laws (*leges*) in the strictest sense of that word. It is, however, convenient to consider in this article all the regulations that were made for the administration of the public land by the executive authorities, as well as by the people during the republic, and by the commands of the emperor, which had the force of law during the principate.

Public land was the prize of conquest and was one of the means of defraying the expenses of state administration. For this purpose land was often leased on the condition of the payment of dues. But it was made to fulfil another purpose, the satisfaction of the individual needs of poorer citizens. To this end land was assigned, and on assignment ceased to be the property of the state. But it often happened that the state was not disinterested in such acts of assignment. It gained security and territorial control by planting garrisons in conquered country, and it relieved itself of the necessity of providing for its poorer classes by state-aid. The connection between agrarian legislation and colonization can be seen at once, and also the two aspects of colonization—the military and the social. These two objects were connected throughout the whole of the earlier period of Roman agrarian assignment. After the time of the Gracchi social motives continued to be operative when military precautions had ceased to be necessary. One of the motives which prompted infant Rome to war with her neighbours was the land-hunger of her citizens. This hunger she satisfied after conquest by annexing a portion of the enemy's territory. The amount thus confiscated varied. It was usually a third, but sometimes a half or even two-thirds, and after the fall of Capua in the Second Punic War the whole territory of the state was annexed. By the close of the 2nd century B.C. one-half of the land of Italy belonged to Rome whether in private ownership or as the property of the state. Annexation was carried on in the provinces on a smaller scale; but Rome retained as domain-land much of the territory of communities which had been destroyed (e.g., Carthage and Corinth), and the estates of former kings. This peculiar property of the Roman state in the provinces must be carefully distinguished from the general overlordship which Rome was supposed to hold over all provincial soil, expressed in the statement that provincials had only possession or usufruct of land.

Methods of Handling Public Land.—Such portions of the territories of conquered cities as were not claimed by Rome were left in the possession of these cities. If the city was a federate state (*civitas foederata*) this possession was guaranteed by a treaty; if it was a free city, the guarantee was made by charter; where Rome had marked out territory for assignment to her own citizens, but where, in or near the limits of the assignment, some of the land had been left in the hands of its former proprietors, such land was noted in the state registers as *redditus veteri possessori*.

The State dealt in two ways with such land as it retained. It alienated it, in exchange for a price or gratuitously; or it kept it as a source of revenue, whether on lease or on some system of remunerative occupation. The land might be sold for the benefit of the treasury. Typical instances of this treatment are furnished by the sale of some Campanian land during the Second Punic War. The censors may have directed the sale, but it was executed by the quaestors as the regular officials of the treasury. Hence such land was described as *ager quaestorius*. The land was sold in definitely marked out plots, and when this sale had been effected the lots fell under the absolute ownership of their purchasers.

The second mode of alienation was that by assignment. Lands thus assigned were known as *agri dati adsignati*. The gift on the part of the State was gratuitous, and ownership passed wholly to the assignee. The land so given was definitely surveyed, marked out, and registered. Such an assignment might take one of two possible forms. It might be the means of establishing a new "plantation" (*colonia*), with some independent organization of its own, or it might be the means of providing allotments for individuals who remained domiciled at Rome or in some already existing municipality. The amount granted to individuals in assignments of both types varied from time to time. It was reckoned in terms of the *iugerum*, which was approximately five-eighths of an English acre. The earliest and smallest assignment was two *iugera*:

14 *iugera* was the maximum amount granted before the time of Ti. Gracchus (133 B.C.), and it was held by representatives of the old school that seven *iugera* were as much as any frugal Roman should want. The division was carried out by commissions appointed by the people. The land which the State retained as *ager publicus* was always placed in the hands of individuals, who occupied it in some manner remunerative to the State. These individuals (*possessores*) were never regarded as owners of the land thus occupied. It remained the property of the State, was held without a contract (*precario*), and could be resumed by the State at will. But though the tenants had no claim against the State, their ownership could be defended against all other claimants; from an early date the praetor's possessory interdict was used to protect all occupiers, provided their tenure had not been acquired by force (*vi*), by seizure of land in its occupiers' absence (*clam*), or by mere permission of the previous holder to occupy (*precario alter ab altero*). Tenants of this type could transfer their land by inheritance, and the land was accepted as security by creditors. This kind of occupation, therefore, though clearly distinguished from ownership (*dominium*), was yet regarded as a perfectly secure form of tenure. All occupiers of public land paid dues to the State through a state contractor (*publicanus*). These dues varied in amount and in the method of their collection. We learn from Appian that the ordinary dues paid by occupiers of arable land in Italy were one-tenth of seed crops and one-fifth of plant produce. Owners who turned cattle or sheep on pasture land belonging to the state also paid fixed dues to the treasury. The occupiers of the Roman public land in Campania paid a large rent. The conditions of the tenure of the Roman public land in Africa are known to us from the *Lex Agraria* of 111 B.C. The *publicanus* is the middleman between the State and the *possessor* and purchases from the censor the right of collecting dues. The law places no restriction on bargaining between the censor and the *publicanus*, but enacts that no *possessor* or *pastor* shall ever be required by the *publicanus* to pay more than the amount prescribed by the censors of 115 B.C. These conditions may be regarded as typical for the occupation of public lands. When Cicero speaks of public land as let on lease (*locatus*) by the censor, he refers to the leasing of the taxes to a *publicanus* for a fixed period, and not to the letting of the land. This seems clear from a passage (*In Verr.* iii. 6, 12) where he speaks of land in Sicily which had been restored by Rome to former owners as being leased. The land itself could not be leased by Rome if it belonged not to Rome but to the Sicilian inhabitants; but the collection of the revenues due to Rome could be so leased to *publicani* (*q.v.*). The same explanation would apply to Cicero's statements that the Campanian land was let on lease by the censors. Cicero's repeated statement that the Campanian land was expressly exempted from the legislation of the Gracchi shows that there was not sufficient distinction between the Campanian tenure and that of other public land in Italy to make this definite exception by name superfluous. The Sempronian law could obviously not touch land which the State had leased to occupiers on the basis of a definite contract. It seems certain that in every case the *possessor* occupied *precario*, and that only in the bargain between the censor and the middleman was there room for contract. Thus the State was justified in the claim to resume public land which it made in many of the agrarian laws.

Survey of Agrarian Legislation.—The earliest agrarian measures of which we have any record are the distributions to poor citizens of land conquered in war, which later authorities attribute to Numa and Servius Tullius. Such assignments were a voluntary surrender on the king's part of his own portion of the spoils. The agrarian law of Spurius Cassius (486 B.C.) distributed *ager publicus* among the plebeians. Another agrarian law proposed by the tribune Lucius Icilius in 456 B.C. regulated the tenure of public land on the Aventine. In 376 B.C. the tribunes Licinius and Sextius introduced into their laws, for the promotion of the privileges of the *plebs*, a clause enacting that no more than 500 *iugera* of land should be occupied by a single cultivator; the law also enacted that only 100 cattle and 500 sheep might be turned by one owner on the public pastures. But it failed of its object because it did not provide any adequate machinery for the resumption by

the state of land held in excess of the prescribed amount, and was therefore easily evaded. The next agrarian law was a measure dealing with lands conquered from the Senones (*q.v.*) and Picentines. In 232 B.C. C. Flaminius, tribune of the *plebs*, proposed to resume these lands for the state, although they were already occupied by large landholders, and to distribute them in allotments to poor citizens. The measure met with much opposition from the richer classes, and did not gain the sanction of the senate; but C. Flaminius ignored constitutional usage and brought it direct before the council of the *plebs*, by which it was made law. In 133 B.C. the tribune Tiberius Gracchus (*q.v.*) re-enacted the earlier measure of Licinius and Sextius, with the additional provisions that each owner might occupy 250 *iugera* for each son, in addition to the original 500, and that a commission of three (*III. viri agris dandis adsignandis*) should be appointed to carry out the terms of the law. He also enacted that the land occupied in excess of the prescribed amount, and on that account resumed for the State by the land commission, should be distributed in inalienable lots to poor citizens. Subsequent modifications of those provisions which dealt with the powers of the land commission led to a re-enactment of the whole by C. Gracchus (*q.v.*), the brother of Tiberius, tribune in 123 B.C. But within 15 years from the tribunate of C. Gracchus the whole of his law had been rendered null by three further enactments. The first of these permitted the sale of land allotted under the law, which thus tended to return into the hands of its former occupiers as private property, which the State had no longer any right to resume. The second abolished the commission appointed to carry out the terms of the law, thus putting a stop to further resumption and distribution, and also transformed existing occupiers into owners of the land they occupied, paying only a small due to the treasury. The third abolished the payment. That law belonged to the year 111 B.C.

From that time forward a change came over land legislation. The ordinary public land in Italy, in the hands of occupiers, which had given rise to all the agrarian legislation between 376 and 111 B.C. had practically ceased to exist. The Campanian land still remained, but the same reasons which led to its exemption from the Gracchan legislation seem to have continued to protect its holders until 63 B.C. In the meantime several agrarian laws were passed which provided for the distribution of land placed in some other way at the disposal of the State. In 100 B.C. Apuleius Saturninus (*q.v.*) tribune, proposed the allotment of lands recently taken from the Cimbri in Gaul. This law was passed but eventually declared null by the senate, with the rest of Saturninus's laws. A more dangerous precedent was set by Sulla in his dictatorship (82–81 B.C.). He was the first to confiscate the lands of his political opponents and of communities which had resisted him and, treating them as *ager publicus*, assign them to his veterans as a prize. This example was followed by Octavian (Augustus) and Antony (M. Antonius) after their proscriptions in 43 B.C. A third method of providing land for distribution was that adopted by Servilius Rullus (*q.v.*) in 63 B.C. His bill enacted that land should be purchased in Italy with money gained by the sale of Roman territories abroad, and allotted to citizens. A commission of ten (*X. viri agris dandis adsignandis*), annually elected by nine out of the 35 tribes, was to carry out the terms of the law. Rullus also ventured to propose the distribution of the Campanian land which had hitherto been respected by all agrarian reformers. It was chiefly on this ground that Cicero in his three speeches on the Agrarian law succeeded in exciting such a general feeling against it that it was eventually withdrawn. In 60 B.C. the tribune L. Flavius brought forward a bill for the distribution of lands to Pompey's veterans. The Campanian land was certainly to be included in the distribution, and it is clear from Cicero that the bill in some way dealt violently with the rights of private owners. It also, however, enacted that land should be purchased by the State with the wealth which Pompey's conquests had brought into the treasury. The last proposal was supported by Cicero, but the bill seems to have been dropped, only to reappear in more moderate form in the following year. A consular bill, the *lex Iulia Campana*, was passed by Julius Caesar in 59 B.C., which provided for the settlement of Pompey's veterans on the Campanian land, and other lands pur-

chased by the state from private owners in Italy with the full consent of the latter. In its original form, the bill omitted all reference to the Campanian land, which seems to have been included by Caesar in the distribution only when the continued and unreasonable opposition of the senate had goaded him to extreme measures. A commission of twenty was to be appointed to carry out the law, from which Caesar himself was expressly excluded. This measure finally settled the question of the Campanian land, which now passed out of the category of *ager publicus*. The last agrarian law of the republic was that passed in 44 B.C. on the proposal of the consul M. Antonius. We have no detailed account of the measure, but it seems to have provided grants of land for veterans, and was to be administered by seven commissioners. The law was afterwards cancelled by decree of the senate.

AGRARIAN MOVEMENT: see *LAND TENURE: Economic and Agrarian Aspects*.

AGREDA, MARIA FERNANDEZ CORONEL, ABBESS OF, known in religion as Sor (Sister) Maria de Jesus (1602–1665), was born at Agreda, on the borders of Navarre and Aragon, on April 2, 1602. All her family were powerfully influenced by the ecstatic piety of Spain in that age. From childhood she experienced ecstasies and visions. When she was fifteen the whole family entered religion. Maria, her mother and sister established a Franciscan nunnery in the family house at Agreda, which, when Maria's reputation had extended, was replaced by the existing building. She began it with one hundred reals (one pound sterling) lent her by a devotee, and it was completed in fourteen years by voluntary gifts. Much against her own wish, we are told, she was appointed abbess at the age of 25. Though the rule required the abbess to be changed every three years, Maria remained the effective ruler of Agreda till her death. In the earlier part of her life, while the Franciscan, Francisco Andres de la Torre; was her confessor, she wrote an *Introduction to the History of the Most Blessed Virgin*. It was destroyed by the direction of another confessor. Later on, under the guidance of her Franciscan confessor, Andres de Fuen Mayor, she wrote *The Mystic City of God*. It is an extraordinary book, full of apocryphal history, visions, and scholasticism. In 1642 she sent to Philip IV. an account of a vision of a council of the infernal powers for the destruction of Catholicism and Spain. The king visited her when on his way to Aragon to suppress the rebellion of Catalonia. A long correspondence, which lasted till her death on March 29, 1665, was begun. The king folded a sheet of paper down the middle and wrote on the one side of the division. The answers were to be written on the other and the sheet returned. How far Maria was only the mouthpiece of the Franciscans must of course be a matter of doubt. Her correspondence was apparently suspended whenever her confessor was absent. The letters are in excellent Spanish, are curious reading, and are invaluable as illustrations for the second part of the reign of Philip IV.

The correspondence of Sor Maria with the king has been published in full by Don F. Silueta, *Cartas de la Venerable Madre Sor Maria de Agreda y del Señor Rey Don Felipe IV.* (1885). *The Mystic City of God* continued to be much in favour with supporters of the dogma of the Immaculate Conception. It appeared in Madrid in 1668, with a biographical introduction by Samaniego, has been often reprinted, and was translated into French and Italian. It was for a time reserved by the Index, both Spanish and Papal, but was taken off by the influence of the Franciscans and of Spain, the chief supporters of the Immaculate Conception. An account of Maria de Agreda will be found in the *Tracts* of Michael Geddes (1706), vol. ii., written by a competent critic and Anglican divine of the 18th century who detested "enthusiasm."

AGRÉMENTS (Ital. *abbellimenti*; Ger. *Manieren*; Eng. *ornaments*), in music, are supplementary notes, or embellishments, introduced for the purpose of enriching, elaborating or otherwise altering the effect of the phrase or melody to which they are applied. As employed in connection with the older types of music, alike vocal and instrumental, they assumed a large variety of forms (*acciaccatura*, *appoggiatura*, *arpeggio*, *mordent*, *shake*, *turn*,

and so on) which in course of time became definitely standardized and so formed an essential part of the music, although nominally left to the discretion of the performer and indicated, if at all, only by conventional signs.

AGRIANES, a warlike tribe anciently inhabiting Upper Macedonia, and part of what is now south-western Bulgaria. They provided some of the most active and dangerous of the troops of Alexander's army, distinguishing themselves at the Granicus, Issus and on the banks of the Jhelum.

AGRICOLA, GEORG (1490–1555), German scholar and man of science, known as "the father of mineralogy," was born at Glauchau in Saxony on March 24, 1490. The name Agricola is the Latinized form of the German Bauer. His early studies were in philology, but he took his degree in medicine in Italy. On his return to Germany he settled as practising physician in the Joachimstal, a centre of mining and smelting works, his object being partly "to fill in the gaps in the art of healing," partly to test what had been written about mineralogy by careful observation of ores and the methods of their treatment. *Bermannus, sive de re metallica dialogus*, the first attempt to reduce to scientific order the knowledge won by practical work, brought Agricola into notice. (This work was translated by Mr. and Mrs. Herbert Hoover.) In 1530 Prince Maurice of Saxony appointed him historiographer with an annual allowance, and he migrated to Chemnitz, the centre of the mining industry, in order to widen the range of his observations. His chief interest was in mineralogy; but he occupied himself also with medical, mathematical, theological, and historical subjects, his chief historical work being the *Dominatores Saxonici a prima origine ad hanc aetatem*, published at Freiberg. In 1544 he published the *De ortu et causis subterraneorum*, in which he laid the first foundations of a physical geology and criticized the theories of the ancients. In 1545 followed the *De natura eorum quae effluunt e terra*; in 1546 the *De veteribus et novis metallis*, a comprehensive account of the discovery and occurrence of minerals; in 1548 the *De animantibus subterraneis*; and in the two following years a number of smaller works on the metals. His most famous work, the *De re metallica, libri xii.*, was published in 1556, though apparently finished several years before, since the dedication to the elector and his brother is dated 1550. It is a complete and systematic treatise on mining and metallurgy, illustrated with many fine and interesting woodcuts and containing, in an appendix, the German equivalents for the technical terms used in the text. He died at Chemnitz on Nov. 21, 1555.

See article by Gümbel in *Allgem. Deutsche Biog.* (1875); F. A. Schmidt, *Georg Agricola's Bermannus mit Einleitung* (Freiberg, 1806).

AGRICOLA, GNAEUS IULIUS (A.D. 37–93), Roman general, father-in-law of the historian Tacitus, was born on June 13, A.D. 37 (according to others, 39) at Forum Iulii (Fréjus) in Gallia Narbonensis. His grandfathers were of equestrian rank; his father became a senator, but was put to death by Caligula. Agricola was brought up by his mother at Massilia. He entered the army and served (59) under Suetonius Paulinus in Britain. In 61 he returned to Rome, where he married Domitia Decidiana, a Roman lady of distinction. In 63 he was quaestor in Asia, in 65 tribune, in 68 praetor, and when Vespasian was proclaimed emperor, he immediately declared himself his supporter. In 70 he was appointed to the command of the 20th Legion in Britain, then stationed at Deva (Chester). On his return to Rome, at the end of three years, he was made censor, raised to the rank of patrician, and appointed governor of Aquitania (74–78). Appointed *consul suffectus* in the following year, he was admitted into the college of pontiffs and made governor of Britain. In the same year he betrothed his daughter to Tacitus.

Agricola spent at least seven years in Britain. After conquering the Ordovices in North Wales and the island of Mona (Anglesey), during the next two years he advanced to the Taüs (Tay; others read Tanaus, perhaps the north Tyne), and in his fourth campaign fortified the country between Clota and Bodotria (the firths of Clyde and Forth) as a protection against the attacks of the Caledonians. Having explored the coasts of Fife and Forfar, he gained a decisive victory over the Caledonians under Galgacus at the

Graupian hill. (See BRITAIN: Roman.) Between campaigns he busied himself in helping forward the Romanization of his province. But his successes had aroused the suspicion of Domitian. He was recalled to Rome, where he lived in retirement, refusing the proconsulship of Asia. He died in 93, poisoned, it was rumoured, by the emperor's orders.

See Tacitus, *Agricola*; Ulrich's *De Vita et Honoribus Agricolae* (1868); Dio Cassius, xxxix. 50, lxvi. 20; T. Mommsen, *Provinces of the Roman Empire* (Eng. trans., 1886), i. 183-184, 194.

AGRICOLA, JOHANNES (originally Schneider, then Schnitter) (1494-1566), German Protestant reformer, was born April 20, 1494 at Eisleben, whence he is sometimes called *Magister Islebius*. He studied at Wittenberg, where he met Luther. In 1519 he accompanied Luther to the great assembly of German divines at Leipzig, and acted as recording secretary. He taught and preached the Lutheran doctrine in Frankfurt, Eisleben and Wittenberg, but in 1536 an old controversy broke out more violently than ever. Agricola was the pioneer of the Antinomian heresy, which maintained that while the unregenerate were still under the Mosaic law, Christians were entirely free from it, being under the gospel alone. During the bitter controversy with Luther that followed, Agricola in 1540 left Wittenberg secretly for Berlin, where he addressed a letter to the elector of Saxony, which was generally interpreted as a recantation of his views. Luther, however, was not satisfied, and Agricola remained at Berlin, where Joachim II. of Brandenburg appointed him court preacher and general superintendent. With Julius von Pflug and Michael Helding, he prepared the Augsburg Interim of 1548. He endeavoured in vain to appease the Adiaphoristic controversy (see ADIAPHORISTS). He died during an epidemic of plague on Sept. 22, 1566.

BIBLIOGRAPHY.—See Cordes, *Joh. Agricola's Schriften möglichst verzeichnet* (Altona, 1817); *Life* by G. Kawerau (1881), who also wrote the notice in Hauck-Herzog, *Realencyk. für prot. Theol.*

AGRICOLA, RODOLPHUS (properly ROELOF HUYS-MANN) (1443-1485), Dutch scholar, was born at Baflo near Groningen, Aug. 23 1443. He was educated at Louvain, Paris, and at Ferrara, where he attended the lectures of the celebrated Theodorus Gaza (1400-78) on the Greek language. In 1482, on the invitation of Johann von Dalberg, bishop of Worms (1445-1503), he accepted a professorship at Heidelberg, and for three years delivered lectures there and at Worms on the literature of Greece and Rome. By his personal influence much more than by his writings he did much for the renaissance of learning in Germany; and Erasmus and other critics of the generation immediately succeeding his own are full of his praises. He died at Heidelberg on Oct. 28 1485. His principal work is *De inventione dialectica, libri iii.*, in which he attacks the scholastic philosophy of the day. His collected works were edited by Alard (Cologne, 1539).

See T. F. Tresling, *Vita et Merita Rudolphi Agricolae* (Groningen, 1830); v. Bezold, *R. Agricola* (München, 1884); and Ihm, *Der Humanist R. Agricola, sein Leben und seine Schriften* (Paderb., 1893).

AGRICULTURAL ARTICLES. Agriculture is treated in these pages under various headings, an enumeration of which will help the reader to consult any part of the subject.

For a general account of agriculture, reference should be made in the first place to the article AGRICULTURE: A General Survey, and to the sections on agriculture appended to the articles on the different nations.

As to the operations of agriculture, see the articles CULTIVATION; SOIL; SOWING; FERTILIZERS; DRAINAGE; PLANT BREEDING; ROTATION OF CROPS; DRY FARMING; ARABLE; WEED DESTRUCTION; REAPING; THRESHING; AGRICULTURAL MACHINERY AND IMPLEMENTS; ELECTRICAL POWER IN AGRICULTURE; TRACTORS; etc.

The business and organization of agriculture will be found treated under AGRICULTURAL CO-OPERATION; AGRICULTURAL CREDIT; AGRICULTURAL ECONOMICS; AGRICULTURAL EDUCATION; AGRICULTURAL INSURANCE; AGRICULTURAL ORGANIZATION, and AGRICULTURAL RESEARCH. Reference should also be made to the articles on ALLOTMENTS; SMALL HOLDINGS; FARM ORGANIZATION AND EQUIPMENT; FARM MANAGEMENT, and FARM VALUATION.

LAND TENURE is treated under that heading, and there is an article on FARM RENTS. The various institutions connected with agriculture are treated under the headings: INTERNATIONAL INSTITUTE OF AGRICULTURE; AGRICULTURE, CHAMBER OF; AGRICULTURAL SOCIETIES AND SHOWS; ALLOTMENTS ORGANIZATION SOCIETY.

For a discussion of farm relief legislation since 1928 in the United States see FEDERAL FARM BOARD.

For statistics, see AGRICULTURAL STATISTICS; AGRICULTURE, CENSUS OF, and AGRICULTURAL PRICES.

As to agricultural employment, the articles AGRICULTURAL LABOURER; AGRICULTURAL WAGES; AGRICULTURAL WAGES BOARD, and RURAL SOCIOLOGY should be consulted.

Coming to the products of agriculture, in addition to general articles entitled CEREALS and CROPS, each main product is given special treatment under its own heading. Thus, the cereals WHEAT, BARLEY, OATS, MAIZE are the subject of special articles. GRAIN PRODUCTION AND TRADE have lengthy treatment.

ROOT CROPS are given a heading, while TURNIP, POTATO, MANGOLD, etc., have separate articles.

There are also articles on GRASS AND GRASSLAND, HAY and LUCERNE.

As to animals and meat, articles may be consulted on CATTLE, SHEEP, PIG, BEEF, MUTTON, PORK, BACON AND HAM, in addition to the general account under MEAT. There are articles on FEEDING STUFFS and ENSILAGE.

As to dairy work, reference should be made to DAIRIES AND DAIRY FARMING (a general account), and to the articles BUTTER, CHEESE and MILK.

On special subjects, articles will be found under EGGS, FRUIT FARMING, FLOWER FARMING, FLAX, HOPS, BEET, BEE-KEEPING, POULTRY AND POULTRY FARMING.

Finally, the exceedingly important subject of agriculture in the tropics, upon which the livelihood and daily bread of a large section of the world's population may come to depend, will be found treated under the heading TROPICAL AGRICULTURE, while separate headings are provided for tropical and sub-tropical products such as TEA, COFFEE, COCOA, JUTE, RUBBER, GUTTA PERCHA, HEMP, TOBACCO, ARROWROOT, etc.

AGRICULTURAL BUSINESS METHODS: see FARM ORGANIZATION AND EQUIPMENT; FARM MANAGEMENT.

AGRICULTURAL CO-OPERATION. The development of agricultural co-operation has taken widely different courses in various countries according to their specific needs. The main difference to be observed is between countries which are primarily producers of agricultural commodities for export, and those which produce mainly for home consumption. In the former, the co-operative movement has chiefly concentrated upon the organization of marketing; in the latter—apart from the development of rural credit and insurance—mainly upon the purchase of farm requisites, or the formation of co-operative dairy, bacon or other producing societies. Although this broad distinction holds good, it is nevertheless true that practically all types of co-operation are to be found to a greater or lesser extent in the principal agricultural countries.

Co-operation in Great Britain.—Agricultural co-operation in Great Britain may be said to have begun with isolated experiments during the 19th century, but very little resulted from these early attempts. The Agricultural Organization Society in 1901 was the centre of the movement from its formation until it was wound up in 1924. During this period a considerable number of societies were established, as is shown by the fact that their number rose from 33 in 1901 to 1,558 in 1920, and the total membership from 517 to over 200,000.

The post-war period brought forth a considerable intensification of the efforts to promote co-operation amongst British farmers, and the Agricultural Organization Society was assisted by grants from the State. A number of new societies were formed between 1918 and 1924. Unfortunately these efforts met with only limited success, and the creation of new societies was largely offset by a considerable number of failures. This was due to several factors—to the rapid fall in agricultural prices which took place after the spring of 1920, to the fact that a large number of the

new societies were small and financially weak and were therefore unable to secure competent management, to the failure of many societies to adopt certain principles in co-operation which in other countries had proved to be essential, and to the lack of interest shown by farmers themselves.

Amongst agricultural co-operative societies in Great Britain the most successful have been the relatively large-scale societies concerned with the supply of farm requisites, a few dairy societies, and a certain number of others engaged in the sale of eggs, wool, fruit and vegetables, etc. A full description of the requisite societies may be found in the report on "The Co-operative Purchase of Agricultural Requisites" (Economic Series, No. 5) and of societies engaged in the marketing of agricultural produce in the report on "Co-operative Marketing of Agricultural Produce in England and Wales" (Economic Series, No. 1), both published by H. M. Stationery Office.

Mention should be made of the formation of the Agricultural Wholesale Society in 1918, which was an attempt to provide a central wholesale organization from which the local requisite societies could obtain their supplies; its relation to the latter was similar to that between the co-operative wholesale societies and the retail consumers' co-operative societies. Such central wholesale societies had for some years been an integral part of the agricultural co-operative organization in several European countries, as will be seen below. Although the turnover of the Agricultural Wholesale Society amounted to no less than £1,890,000 in 1919, with the sharp fall in prices which began in 1920, the society was involved in difficulties, and for this and other reasons it failed and was brought to an end in 1924. (*See AGRICULTURE.*)

In 1924 the total number of agricultural co-operative societies in Great Britain were 1,631 (including 52 societies connected with the fishing industry), having a total membership of 298,401.

Co-operation in Europe.—In western Europe, where the majority of countries are importers of food or are approximately self-supporting, the growth of co-operation has been mainly in the direction of developing rural credit societies (*see AGRICULTURAL CREDIT*) or of societies for the purchase of agricultural requisites, though often combining these functions with that of the sale of produce. But even here, Denmark, conducting a considerable export trade, has developed its marketing organizations on co-operative lines in addition to its highly organized system of supply societies; indeed it has been the model upon which many of the marketing organizations in the newer countries have been based.

Leadership in agricultural co-operation belongs to Germany and Denmark. Of the 38,000 agricultural co-operative societies in Germany in 1924, there were 19,000 rural banks, 4,700 purchase and sale societies, 3,500 dairies and 10,000 societies for other purposes, together with 98 "central" societies. In 1920 Denmark possessed more than 5,000 co-operative associations, including over 1,600 consumers' societies, 1,100 creameries, 40 bacon factories, besides a number of central associations, export associations and co-operative bodies for various minor purposes.

A general characteristic of the European co-operative movement is that both in its origin and subsequent development there has been a certain idealism which has given it a special vitality. Thus, in Denmark, the movement was associated with a moral educational revival accompanied with the development of the people's high schools; in Belgium the co-operative organization had a basis of religious and social culture; in Germany the birth of the co-operative credit movement was largely a question of the social regeneration of the rural population. In most of these cases it started with the clubbing together of a small number of villagers to carry out a common object, whether it was the purchase or sale of produce, or the provision of credit. But, although built up upon this small foundation, the movement has gradually assumed a different character through the consolidation of the small units into large federated organizations, the gradual centralization of control, and the development of many of the features of big-scale enterprise. Indeed, federation describes in a word the modern development of the co-operative movement in most agricultural countries.

The main divisions of the co-operative movement in Europe are supply, production, marketing, credit and insurance. Other minor, but important, branches, are the co-operative use of farm machinery, cattle breeding, the supply of electric light and power, the manufacture of potato meal and potato alcohol, forestry and fishing.

Supply Societies.—These have aimed at purchasing agricultural requisites in bulk at wholesale prices and delivering them to members at cost. They have been widely developed upon "Rochdale" principles, the goods being delivered to members at certain fixed prices and the profits of the societies being distributed amongst its members as a "dividend" in proportion to the gross amount of their purchases. This principle applies in many European countries, though an exception is to be found in France, where the profits of the "syndicats" go to the formation of a reserve fund which belongs to the members equally, irrespective of the amount of their purchases. The recent tendency in the development of these societies is to federate the local distributive societies to central wholesale societies on the general plan of the British distributive movement.

In Germany, the pioneer society in the movement towards wholesale federation was the Haas Society at Insterburg, founded in 1871. This example was subsequently followed by the rest of Germany, membership of the provincial wholesales being usually confined to the local distributive societies. The first permanently successful federation amongst consumers' stores in Denmark started in 1884 with the formation of the Co-operative Wholesale Society of Denmark amongst the societies on Zealand (Sjælland), for the supply of farm requisites as well as ordinary household requisites. Four years later a similar wholesale society was started in the Jutland Peninsula, and in 1896 these two were amalgamated into one organization—the Co-operative Wholesale Society of Denmark. Since then it has made remarkable growth, the number of consumers' societies which were members of the wholesale having risen from 310 in 1896 to 1,259 in 1910 and 1,805 in 1922. The Co-operative Wholesale Society is a member of the Scandinavian Co-operative Wholesale Society, which is a joint buying organization for the wholesale societies of Denmark, Norway and Sweden.

In Switzerland very similar progress has been made. The Verband-Ost-Schweizerischer-landwirtschaftlicher-Genossenschaften was formed as a central society. The business was divided into two departments—the agricultural, dealing with seeds, manures, cattle food, etc., and the store department, dealing with household requisites. The organization has also undertaken the sale of members' produce, though its supply side remains its more important function.

In France, the local, and more particularly the communal, "syndicats agricoles," have united in departmental unions, and these unions have formed the starting point of larger organizations—the "unions regionales." The growth of the movement in France may be judged from the fact that the number of syndicats rose from 39 in 1885 to 4,948 in 1910, and to 6,667 in 1914. In the latter year the total membership exceeded 1,000,000 persons.

Production Societies.—Probably the most successful branch of productive co-operation is to be found in the dairy societies existing in large numbers in all countries in which agricultural co-operation is firmly established. Leadership again belongs to Germany and Denmark, the former having as many as 3,491 co-operative dairies in 1924, while the latter had some 1,118 at the outbreak of the World War. Switzerland, France, Holland, Belgium and some of the countries of south-eastern Europe have also made considerable progress in recent years. Ireland, one of the most successful countries in developing co-operative creameries, had, in 1921, 336 of these societies. (*See CREAMERIES.*)

Mention should also be made of the bacon factories and egg and poultry societies, the former of which have been brought to a high degree of efficiency in Denmark. In 1922 there were 40 bacon factories, dealing with 2,215,000 pigs per annum. These are factories requiring a considerable amount of capital and provided with subsidiary plants for the disposal of by-products. They are usually financed by loans jointly and severally guaranteed by the

members, and receive the pigs from members under contracts binding them to supply their whole output for a period of years. The individual bacon factories are federated in the National Federation of Danish Co-operative Bacon Factories, with head offices in Copenhagen. One of the most remarkable achievements of this co-operative organization is the improvement of breed which it has enabled producers to bring about. A close study of the requirements of the British market (the principal export market) combined with scientific pig breeding under the supervision of the Government and the National Federation of Co-operative Bacon Factories, has led during the last 30 years to an improvement in quality, without parallel in other countries.

Marketing.—To Denmark also belongs the credit of co-operative marketing which has lately been developed on an enormous scale in the newer countries. The tendency is to establish strong central selling or export agencies of which local productive societies are members. The need for co-operation amongst the local co-operative societies gave the impulse towards the centralization of marketing, and the formation of provincial and ultimately national associations, but many difficulties were experienced before the structural development of the marketing organizations was complete. The turning point was reached when the principle of binding contracts for the supply of produce was adopted. Under this system the members of a local co-operative marketing association undertook to supply the whole of their produce to their society for a term of years. The term ranges from one to as many as 20 years. On this firm foundation it has been found possible to build up the modern organization which markets the greater part of Danish agricultural produce. The local units, having a democratic membership control, are usually federated to the central society on "commodity" lines, that is to say, the federation of local societies is usually concerned with one agricultural commodity or commodities of closely allied character. Members are paid for produce by an advance at the time of delivery followed by a distribution of the profits at certain intervals. The produce thus delivered is classified and graded at the headquarters of the association, and the initial payment is made on the basis of this classification. For the purpose of marketing, the produce is "pooled." These principles—contracts, commodity organization and pooling—form the basis upon which a great part of Danish co-operative marketing is conducted, and have been widely copied in America, Canada, Australia and elsewhere.

The benefits which agriculture has derived from the European co-operative system are many. By the centralization of purchase and of sale, considerable economies have been effected, not merely in consequence of the elimination of the middleman and of bulk handling of the produce, but by the removal of the powers of exploitation which buyers and sellers of agricultural commodities not infrequently exercised over unorganized farmers. In organized marketing, large-scale handling has enabled scientific grading and standardization to be carried out, which in turn has led to the production of standard grades of produce and standard breeds of live stock on the farms. This again, as in the case of bacon, has led to a general improvement in the quality of farm produce, and has greatly added to the competitive strength of the central export associations in foreign markets. Their products have earned a reputation for uniformity and sustained high quality against which unorganized farmers have found it increasingly difficult to compete.

Canadian Wheat Pools.—Canada affords some remarkable examples of the development of large scale co-operative marketing enterprise, of which the wheat organization is the most significant. The Saskatchewan Co-operative Elevator Company (which handled in 1922-23 about one-fifth of the grain produced in the province, amounting to over 40,000,000 bu.) originated in the widespread discontent which was felt by farmers at the growing powers of the elevator companies. In 1924 it owned 425 country elevators, and as development took place it was found necessary for the institution to own terminal elevators and "hospital" elevators for treating damaged grain, and it has at the present time over 6,500,000 bu. of capacity in terminal and hospital storage.

Alberta followed the lead of Saskatchewan by setting up the Alberta Farmers' Co-operative Elevator Company in 1913, and four years later this company was taken over by the United Grain Growers, Limited. Within recent years, the movement towards centralized marketing has undergone further important developments. For the purpose of selling, an organization known as the Saskatchewan Co-operative Wheat Producers, Limited, was formed, with headquarters at Regina. Members of the company, who already form a substantial proportion of the wheat growers in the province, enter into a five years' contract to sell the wheat through the company. Very similar arrangements have been made in Manitoba and Alberta, the respective organizations being the Manitoba Co-operative Wheat Producers, Ltd., with headquarters at Winnipeg, and the Alberta Co-operative Wheat Producers, Ltd., with headquarters at Calgary. To complete the system of centralization only one step remained, namely, to unite the three provincial pools into one organization. This step has now been taken. The Canadian Co-operative Wheat Producers, Ltd., with headquarters at Winnipeg, was formed as the central selling agency for the above three producers' pools, and operated for the first time in respect of the 1924-25 crop. It then represented more than 127,000 farmers. The handling of milk, butter and cheese, the marketing of wool, live stock, poultry and eggs, fruit and other produce by co-operative enterprise has also made considerable advance in Canada since the World War.

Australian Wheat Pools.—The co-operative wheat pools of Australia are an example of a somewhat different character, since they came into being as the result of direct State action in order to meet the abnormal conditions during the War. They have brought about a fundamental change in the system of marketing wheat in that country. The original scheme was compulsory. It was entered into by the Governments of the Commonwealth, the States of New South Wales, Victoria, South Australia and Western Australia for the purpose of realizing to the best advantage the wheat harvests of the respective States, and for making advances to farmers pending the realization. The scheme was first applied to the 1915-16 crop, and it was subsequently decided to deal with the succeeding crops on the same principle. This actually took place in respect of each crop up to that of 1920-21. The duty of realizing the crop was placed in the hands of the Australian Wheat Board, consisting of ministerial representatives of the Governments of the Commonwealth and the respective States, and one representative of the growers from each State.

In each State a local board or commission controlled the operations of the scheme within its area, and the local board effected all local sales, including sales to millers. Under arrangements with the Australian banks made by the Commonwealth and State Governments, advances were made to farmers upon delivery of their wheat at railway stations to the appointed representatives. The proceeds of the wheat sales were applied, as realized, in reduction of the bank over-drafts which had been used for the payment of advances and expenses. In 1922 the compulsory pooling of wheat was abandoned, but the principle of pooling the exportable surplus was continued on a voluntary basis under the respective State Governments. Under this scheme, as in the case of the compulsory scheme, each State ultimately receives, in respect of the grain actually shipped, the average net profit from the overseas realizations, which, after paying expenses, is distributed *pro rata* amongst the growers. This system of pooling remains in operation (though some doubt has been expressed as to its future), and the grain exported to the United Kingdom is distributed there through the Australian Wheat Pools Agency, consisting of two firms, which receive and market the whole of the wheat exported by the respective wheat pools (with the exception of Victoria, which sells independently) operating upon the British corn exchanges, mostly in London.

Mention must also be made of the rapid growth of agricultural co-operation in India, which has mainly taken place during the present century. Indian co-operation bears a much closer resemblance to European than to the American or Australian systems. As in Germany, it has been developed largely to provide credit (and insurance) facilities, and to a limited extent for the

purchase of requisites and the sale of produce. Its remarkable growth may be judged from the figures. The total number of co-operative societies in 1907 was 149; in 1914 it was 15,673; at the end of the War 26,465; and in 1922 it had reached 52,000. Of this total, 46,700 are agricultural societies, 3,600 are non-agricultural, 1,200 are supervising and guaranteeing unions, and 480 are central societies, including provincial and central banks, and banking unions. Of the agricultural societies all except 1,165 are credit societies. Production is represented by 302 societies, the remainder being organized for purchase and sale. (R. E.)

THE UNITED STATES

Farmers' Large-scale Co-operation.—In the spacious lands of the world more newly settled, we meet with different economic and social conditions. Great cities are fewer and wider apart. Farmlands extend over broad regions in which masses of cultivators possess a common interest in production of a particular kind. Britain in 1921 had fewer than 500,000 farms. The United States in 1920 included 6,500,000, and these are more specialized. Co-operation can gather together 17,000 Californian farmers interested in raisins, 67,000 in the Eastern States concentrating on milk, 500,000 in the Middle West dependent on exports of grain. Again, of the 6,500,000, nearly 4,000,000 were owned by the occupiers. The position is similar in Canada where a wheat production of 50,000,000 quarters means a mass interest different both in character and in volume from that associated with the 7,000,000 of Britain. So with the wool and wheat of Australia, the fruit of South Africa, the butter and cheese of New Zealand. Add that the farmers are of enterprising, immigrant quality, and nearer to fixed-income conditions than the money-seekers of new industries and commercial cities, and it becomes reasonable to expect forms of co-operation thriving amongst them on a scale comparable with that of consumers' co-operation in Europe.

In 1874 in the United States, the National Grange proposed "working together, buying together, selling together and, in general, acting together for our mutual protection and advancement," and the name of the American Society of Equity, of 1902, recalls that of the Rochdale Equitable pioneers. But it is the selling together which has most appealed to American and Dominion farmers. In the United States, especially aided since 1921 by the Co-operative Marketing Act passed in Texas in that year, and soon adopted in 36 States (in New York in 1924) grain, fruit and vegetables, milk, cheese, eggs, nuts, tobacco, cotton and wool are co-operatively sold. Associations under this law (other bodies may be simply joint-stock) are not to make profits for stockholders as such, but only for members as agricultural producers. Membership must be open to all the producers; interest on stock is not to exceed 8%; and selling for non-members is limited, while the definitive co-operative rule is laid down of no member possessing more than one vote. The solid basis of consumers' co-operation is potential custom. With farmers' co-operation it is the coming crop; and while the co-operative consumer is morally bound to give reasonable custom, the farmer must contract for the season or for a longer period up to five years. In return, instead of having to borrow on his crop or else wait for ready money until it arrives in full, he receives part-payments in advance; and finally he obtains a share in the business surplus in proportion to his contribution to the turnover. Failures are more numerous than in the more closely-organized movements of Western Europe, and bad management was the confessed reason in nearly 30% of the failures during 1900-23; but the very great majority of the associations are successful. And these not only help the grower commercially; they also mitigate the farmers' feeling that he feeds the world, yet is exploited in the very process.

American and Other Examples.—The New York Dairy-men's League is an example of success. The league, dating from 1921, is a non-profit (all profits to members on the Rochdale lines) and non-stock organization, the working capital being derived from membership fees guaranteed by contracts and sales. The league, the largest association of its kind in the world, collects

milk yielded by 750,000 cows, grazing at up to 400 miles from New York, has a complex pooling system, owns refrigerating plants and shops, has research and statistical departments, conducts great advertising campaigns, and employs 3,000 persons. In Canada the wheat pools of Alberta, Manitoba and Saskatchewan—representing 137,000 farmers—and their joint agency, the Canadian co-operative wheat producers, form another conspicuous example. In 1926, this selling agency handled 190,000,000 bushels of wheat, marketed or held back according to conditions. The pool movement exists also in the United States and in Australia (the English C.W.S. through its bank, assisting to finance the latter), and a joint-committee for these continental areas has existed since 1926. The prospect of a producers' restrictive monopoly might be feared, but the pool leaders deny even its possibility, the organizations tending rather to improve the crops both in quality and quantity.

These examples from North America sufficiently resemble those forms which are found in the Argentine, in Australasia and in South Africa, except that since 1921 the co-operative dairy farmers of New Zealand, without actually tying buyer or seller, have entered into a definite partnership with British co-operative consumers through the C.W.S. and the jointly-owned New Zealand Produce Association. The Overseas Farmers' Co-operative Federations of Australia have relations only less close with the same market. (A. W. McK.)

AGRICULTURAL CREDIT. The credit needed in agriculture is of two kinds. The first is long term credit, required to facilitate land purchase or the execution of improvements; the second is short term or personal credit, required to finance the growing, harvesting or marketing of crops, etc. Systems of agricultural credit as they exist to-day in various parts of the world may be roughly distinguished according to whether they are based on a co-operative principle or not. Co-operative credit has been successfully developed in Europe (with the marked exception of Great Britain) and in India. In most of the newer countries co-operative systems have been relatively unsuccessful, and other means of financing agriculture have had to be found.

Great Britain.—There are very few British institutions specifically engaged in providing credit for agriculture, the bulk of farm credit being furnished by the joint stock banks and tradespeople, insurance companies and private mortgages. In regard to long term credit, two institutions (the Farmers' Land Purchase Company and the Lands Improvement Company) have, however, sought to specialize in this business. The former has aimed at lending money on mortgage for land purchase, but its operations have been on a very restricted scale. The latter, founded in 1858 and operating under special acts of parliament, has lent upwards of £13,000,000 for the purpose of carrying out certain types of land improvement. Apart from these, farmers and landowners have mainly had to rely for long term loans on bank overdrafts secured by the deposit of title deeds and private mortgages. In regard to short term credit, for several years prior to the World

War attempts were made to establish co-operative credit societies in Great Britain on the Raiffeisen model (which had had such widespread success in Germany and other continental countries). In 1910 there were 31 co-operative credit societies in Great Britain with 663 members; during and after the War there was a substantial decline in their number and membership.

In 1922 the subject of credit was considered by a committee appointed by the Minister of Agriculture, and its report was published early in 1923. Its recommendations were adopted by the Government, and the Agricultural Credits act 1923 was passed in July of that year. The objects of this measure were: (1) to enable persons who bought their holdings during the currency of the Corn Production acts (April 5, 1917 to June 27, 1921) when prices were exceptionally high, to obtain mortgage loans from the State repayable within a maximum period of 60 years; (2) to establish co-operative credit societies with powers to borrow from the State. The latter were based on limited liability, each member being entitled to hold any number of £1 shares upon which 5s. had been paid up, and to borrow in proportion to his share holding. The credit societies could borrow from the State £1 for each share so held.

Under the first of the above provisions, mortgage loans were granted to the gross value of £5,000,000. Very little interest was, however, taken by farmers in the formation of co-operative credit societies, only nine societies being actually registered under the act, of which four never commenced operations. In view of the small response to this measure, State advances to credit societies were discontinued in March 1927. Subsequently, the Government stated its intention of introducing a bill dealing with this subject.

Germany.—Germany may be regarded as the birth place of co-operative credit in Europe. The typical organizations have been the *Landschaften* or Credit Unions (for long term credit) and the Raiffeisen banks (for short term credit). The former originated as far back as 1770, and gradually extended not only in Germany, but to Denmark, Hungary, Russia, Poland, Norway and elsewhere. The basic principle was the issue by the *Landschaft* of bonds based on estates mortgaged in its favour—the bonds being secured upon the collective guarantee of the members of the *Landschaft*. The borrower was paid not in cash but in bonds which he could realize on the market. He had the right to repay by annuity or by special instalments, or to cancel the loan by purchasing and tendering bonds. *Landschaften* bonds were regarded as first-class securities, and during the period 1910–14 were quoted on nearly equal terms with the loan bonds of the empire. The principle of the Raiffeisen banks, which were empowered both to make loans and to take deposits, was originally that loans were secured by the collective unlimited liability of all the members. Limited liability was, at a later date, adopted by a small number of these societies. In some cases they added to their credit business that of purchasing supplies for the members, such as seeds, fertilizers, coal, etc. Under Raiffeisen's personal guidance the local credit societies were affiliated to central loan banks, which subsequently received assistance from the State. The wonderful growth of these societies into a vast banking organization, without incurring any serious losses, is perhaps without parallel in the history of finance. In 1924, out of 38,000 registered agricultural co-operative societies in Germany over 19,500 were rural banks.

The post-War inflation in Germany, involved the whole credit organization in acute difficulties, and with the collapse of the paper mark, confidence was destroyed and depositors ceased to lend their money. For these reasons German agriculture found itself faced with an extreme shortage of capital, interest rates rose to a very high figure and farm mortgages became, for a period, unobtainable. After the stabilization of the currency and the introduction of the *rentenmark*, drastic reorganization of the credit machinery became necessary. A central institution of agricultural credit, the *Rentenbank-Kreditanstalt*, an off-shoot of the *Rentenbank*, was established, which operated through the previously existing credit institutions. Ultimately, with the aid of loans raised in the United States, the situation was considerably relieved and rates of interest substantially reduced.

France.—The conspicuous feature of agricultural credit in France is the State subsidy which it carries with it. Under the Méline act of 1894 all or part of the members of one or more agricultural *syndicat* could constitute a credit society, whose capital was obtained by subscription of members. The credit society became a *filiale* of the *syndicat*. A considerable growth of these societies took place with the assistance of a voluntary organization which prepared model rules. In 1897 it was made a condition of the renewal of the charter of the Bank of France that it would place at the disposal of the State without interest 40,000,000 francs, together with an annual share in the profits of the bank, for the assistance of agricultural credit. In 1899 regional banks were created, the members of which were the local credit societies, and the above subsidy enabled the regional banks to reduce their rate of interest to the credit societies, and consequently to provide cheap credit to farmers. The number of regional banks in 1921 was 69, with nearly 5,000 credit societies affiliated to them. The extension of the system to the provision of long term credit was made under Acts of 1910 and 1920, which permit a maximum loan of 40,000 francs to individuals to facilitate the acquisition and management of rural properties.

Canada.—In Canada credit unions have been more successful, and over 150 with a membership of more than 66,000 have been organized since 1906, mainly in Quebec and neighbouring provinces. By a number of acts the provinces of Canada have also sought to extend the facilities for short term credit to farmers. These include the Livestock Encouragement act 1917 of Alberta, under which persons may form an association and jointly apply to the Livestock Commissioners for a loan; the Livestock Purchase and Sale act 1913 of Saskatchewan; the Rural Credits act 1917 of Manitoba, and a similar act in Alberta, both designed to promote co-operative credit. Mention should also be made of the Ontario Farm Loan act and the Agricultural Development act passed by the Ontario Legislature in 1921—designed both to assist land settlement and to provide short term loans. As regards long term credit, legislation has been enacted by the separate provinces. Manitoba passed Manitoba Farm Loan act, which became effective in 1917, and was subsequently amended in 1919 and 1921. The act established the Manitoba Farm Loans Association, which serves as the lending agency between the provincial government and the farmers, and is governed by a board of five members including a Commissioner of Farm Loans. Loans are secured upon first mortgages on farm lands and are repayable by annual instalments in 30 years. Saskatchewan has passed legislation on similar lines (the Saskatchewan Farm Loan act 1917), and Alberta has followed the general lines of the Farm Loan act in the United States.

Australasia.—The development of agricultural credit has received and is still receiving a considerable amount of attention in Australia and New Zealand. In most States of Australia State credit institutions, such as State savings banks, make a speciality of providing agricultural credit. A number of acts have been passed in recent years dealing with the subject of rural credit, among which mention should be made of the Commonwealth Bank (Rural Credits) act 1925 making provision for financing producers' organizations in marketing their produce. An account of these measures is to be found in the Australian Year Book 1925. In New Zealand a Royal Commission on rural credit published a report in 1926 which was followed by two acts of parliament, the Rural Advances act 1926 and the Bank of New Zealand act 1926, both designed to assist the development of long term agricultural credit.

India.—The development of agricultural credit in India has mainly followed the European model, and has made consistently steady progress. The first act legalizing co-operative credit societies was passed in 1904. This act was replaced by an Act in 1912 which closely followed the English Friendly Societies act and permitted other forms of co-operation. The number of rural credit societies under this act exceeds 40,000 and these are mainly modelled on the Raiffeisen plan.

THE UNITED STATES

Since the middle of the last century the need for credit in American agriculture has broadened enormously. Primitive pioneer farming required but little capital. During the past seventy-five years, however, a veritable agricultural revolution has taken place. Transportation opened new markets, free lands disappeared and land values soared, farming with machinery became prevalent, hired labour in part replaced family labour, commercial fertilizers came into general use, and improved farming methods were widely adopted.

These changes necessitated larger working capital and farmers became heavy borrowers. The outstanding farm debt (1928) is estimated at more than \$12,250,000,000, carrying an annual interest charge of roughly \$772,000,000.

While the demand for rural credit was thus rapidly expanding, the development of farm credit facilities seriously lagged. Capital was inadequate and often difficult to obtain. This, coupled with serious periodic depressions in agriculture, created chronic discontent with rural credit conditions. After 1900, systematic effort was made to improve the situation. Commissions investigated European rural credit and helped crystallize sentiment in favour of a farm mortgage credit system, which was established under the Federal Farm Loan Act (1916). Although satisfactory provision for farm mortgage and short-time loans apparently had been made, the disastrous years after 1920 strengthened the belief that commercial banks alone could not meet all short-time credit needs of the farmers. As a result the Intermediate Credit System was established (1923). The rural credit system thus includes commercial and private agencies, supplemented with Government-owned or Government-supervised institutions.

Long-term Credit.—Farm mortgage credit for purchasing land or making permanent improvements is used more extensively by farmers than any other form of credit; perhaps two-thirds of the credit obligations of owner-operator farmers is of this type. The first year for which data are available (1910), the mortgage indebtedness of farmers was about \$3,598,985,000. By 1920 it was over \$7,857,000,000; by 1925 it was \$9,000,000,000. Almost 61% of this indebtedness in 1920 was carried by farmers in the East North-Central and West North-Central States, and over two-thirds was on owner-operated farms.

State and national banks have always been primary sources of both long and short-time rural credit. In 1924 loans for agricultural purposes amounted to about 14% of the total bank loans and discounts. In industrial States such loans are relatively small, amounting, in some States, to less than 1% of all bank loans (1924). In the agricultural States, agricultural loans predominate, amounting in some States to 75% of all bank loans and discounts. Bank farm mortgage loans increased from roughly \$740,000,000 in 1914 to \$1,450,000,000 in 1921.

Life insurance companies have been an important factor in the farm mortgage field during the past fifty years. Their farm loans, (principally in the better regions of the Central West and South), increased from \$694,000,000 (1914) to about \$2,000,000,000 in 1927. Insurance companies were responsive to farmers' needs during the recent depression.

Formerly funds for buying land were frequently obtained from neighbours or other individuals in the older sections. Farm mortgage companies, which sold farm mortgages to eastern investors, grew out of this situation. Much farm mortgage credit is advanced by former land-owners and private investors.

The Federal Farm Loan System.—Capital was formerly brought into deficit areas through banks or realty firms, and the practice developed of selling farm mortgage notes in their original form. Usually it was necessary to find a borrower who desired a mortgage of a given amount, and given period, and with definite

terms. An institution was needed through which farm mortgages could be standardized and held as collateral against which bonds could be marketed.

To meet this situation the Federal Land Bank System was established, partly on European models (1916), under the Federal Farm Loan Act. It provides for two types of credit institutions, the Federal Land Banks and the Joint Stock Land Banks, under the supervision of the Federal Farm Loan Board.

There are 12 Federal Land Banks with a paid-up capital of \$750,000. This capital, originally subscribed by the U.S. Treasury, has been largely retired by the borrowers. Loans are made through national farm loan associations, organized by ten or more farmers desiring loans totalling at least \$20,000. In 1928 there were 4,500 to 5,000 farm loan associations serving nearly every county. Each borrower must subscribe to the stock of the Federal Land Bank to the extent of 5% of his loan, and assumes a liability of twice the par value of his stock for losses sustained by the association. It had been intended that the Federal Farm Loan Banks should be co-operative, but the co-operative features did not develop as anticipated, and the Act was amended (1923) to maintain Government control over the System.

Federal Land Banks lend only to actual or prospective farmers.

The maximum loan was raised from \$10,000 to \$25,000. Loans average slightly over \$3,000 and are granted primarily to small farmers. Lands on which loans are made are appraised on their earning capacity. Appraisals have usually been conservatively made, which explains in part the growing popularity of the bonds issued by the System. Loans may be made up to 50% of the appraised value of the land, plus 20% of the insured permanent improvements. The term may extend from 5 to 40 years, at the option of the borrower; it is usually from 33 to 35 years. All loans are made on the amortization plan. Pre-payment privileges are allowed after 5 years. The funds are obtained through the sale of tax-exempt bonds secured by farm mortgages. Each bank may issue such bonds up to 20 times its unimpaired capital and surplus, and is jointly liable for the bonds of the other 11 banks. These bonds are not obligations of the Federal Government, but their supervision by the Federal Farm Loan Board and their tax-exempt feature create a market for them at low interest rates. American farmers are now obtaining farm mortgage credit at rates that compare favourably with those paid by other groups.

Since the organization of the Federal Land Banks 448,958 loans, aggregating \$1,365,060,822 have been closed. Net mortgage loans outstanding December 31, 1927, amounted to \$1,155,643,871.38. Loans are rather uniformly distributed throughout the country, and are made especially in regions where credit has been scarce and costly.

The Federal Farm Loan Act authorized the establishment of Joint Stock Land Banks, privately owned and operated under the Federal Farm Loan Board. They may be organized with a minimum capital of \$250,000. They operate much as do the Federal Land Banks, but they have special features which differentiate them from those banks. Each may operate in only two contiguous States. They may loan to farmers and to owners of land who are not farmers. Their loans are made direct, and not through associations. Borrowers need not purchase stock in the bank, nor is joint liability carried by the borrower. The Joint Stock Land Banks may loan up to \$50,000 to individual borrowers. Their funds are obtained through tax-exempt bonds, which may be issued up to 15 times the unimpaired capital and surplus of the bank, each being liable for its own bonds only.

Early growth of the Joint Stock Land Banks was relatively slow, but since 1921 their development has been rapid. Through liquidations or consolidations only 56 are now in operation out of 80 chartered. These 80 banks have loaned to 114,809 farmers, totalling \$790,304,647. Their net mortgage loans outstanding December 31, 1927, totalled \$609,476,969.56. In contrast with the Federal Land Banks, loans of the Joint Stock Land Bank are concentrated primarily in the best farming regions and are usually considerably larger than those of the Federal Land Banks.

The Federal and Joint Stock Land Banks are playing a vital part in the rural credit system. They have helped to channel funds from surplus to deficit areas and to reduce and equalize

interest rates. They have permitted refunding shorter time loans on terms more suitable to the farming business, and they have minimized foreclosures in times of depression. But there is room for improvement in the operation of the system. Lands are not always scientifically appraised on the basis of their earning capacity. There has been lack of adequate supervision, and practices have crept in, particularly in the administration of the Joint Stock Land Banks, which are not conducive to success. In the main, however, the Federal Farm Loan System has gone far to solve the farm mortgage credit problem.

In some States the permanent school or the teachers' retirement funds are used to make farm loans at low rates and on suitable terms; in others there are State Rural Credit systems patterned on the Federal Farm Loan System. In the main, State credit systems have not been successful; it is doubtful if there is a place for them in the Rural Credit System.

Terms and Conditions of Farm Mortgage Loans.—Additional charges enter into the cost of credit, but interest rates are used as the only available measure of changes in the cost of credit. The trend in interest rates on farm mortgage loans was gradually downward between 1850 and 1909, upward from 1910 to 1921 and then downward again. Significant variations in rates appear between institutions as well as sections. The Federal and Joint Stock Land Banks may not charge borrowers in excess of 6%. During the last few years the rates of Federal Land Banks have varied between 5 and 6% throughout the country. Rates on life insurance loans compare favourably with these rates in regions where they make most of their loans, and at times life insurance loan rates may be slightly lower, but interest rates on bank farm mortgage loans are usually somewhat higher. Even more significant are variations in rates between sections of the country. The level of rates in the East and Central West is much lower than in the South and West—a contrast even more marked in personal and collateral loans. These variations are due, in part, to differences in credit supply and demand, to risk resulting from geographic conditions, to differences in type of farming and in moral hazards, and to defects in the present commercial banking system.

Following the lead of the Federal and Joint Stock Land Banks, there has been a marked tendency for life insurance and farm mortgage companies to extend the term of their loans. State and national banks, however, continue to make farm mortgage loans for shorter periods. Use of the amortization plan of repayment has been gradually extended.

Short-term Credit.—Short-term credit is used to produce and market crops. It probably amounts to from 30 to 35% of the total farm credit. It is largely obtained from commercial banks, but large advances are made by local merchants, implement dealers, live stock and produce commission firms, canning factories, fertilizer companies, cotton factors, live stock loan companies and private lenders.

Short-term cash loans form by far the most important short-time farm credit. Commercial banks are the principal source of such credit. Short-time farm loans in 1920 totalled somewhat under \$4,000,000,000. Since then the volume of such loans apparently has declined. The cost of short-time loans varies from time to time and between sections. Decline in the cost of short-time bank loans has been most marked in regions where the level of rates formerly was abnormally high. Apparently, at least two-thirds of the short-time loans are made on personal security, although live stock, crops, warehouse receipts, stocks and bonds also serve as collateral.

Most complaint has been registered against the term for which banks have made their short-time loans; most of the loans have been made for six months or less. Such periods do not correspond to the needs of the farmers. Renewals are usually granted, and in good times this arrangement is mutually satisfactory to banker and borrower, but in times of distress the borrower is often placed in a precarious position. This complaint was the primary factor in the establishment of the Intermediate Credit System.

To strengthen State and national banks in the general credit structure, the Federal Reserve Act creating the Federal Reserve System was passed in 1913. The Federal Reserve System controls

a large reservoir of capital upon which banks can draw to provide funds for agriculture and industry. Credit is not advanced direct to farmers through the Federal Reserve Banks, but through member banks, which may rediscount their notes, drafts, or bills of exchange acquired from customers. The Act has special provisions favourable to agriculture. Paper issued for farm purposes was admitted for discount and the Federal Reserve Board, under which the System functions, has liberally defined such paper, and the maturity was extended to nine months. Provisions for discounting paper of co-operative marketing associations were also liberalized. Notes, with maturities up to nine months, are now eligible for discount, if the proceeds are advanced to association members for agricultural purposes or for financing the operations of the association. Special recognition is given bankers' acceptances drawn to finance agricultural operations. Those acceptances are eligible for discount with maturities up to six months, provided they are secured by warehouse receipts conveying title to readily marketable staples. The Federal Reserve System is thus an important channel through which banks may obtain additional funds to finance the short-time farm credit needs.

In the South much short-time credit is advanced by merchants, either on open account or on crop lien. In general it is costly, and is frequently a handicap to the unimpeded marketing of crops. Fruit and vegetable commission dealers and brokers advance much credit to growers. Until recently, live stock loan companies were active in financing the western live stock industry, but the crash in live stock prices ruined most of them. In some sections Credit Unions or associations have been formed to promote thrift among their members, but Credit Unions are not essentially rural institutions.

The Intermediate Credit System.—Collapse of farm prices in 1920 brought a crisis in rural credit conditions, with which commercial banks were unable to cope. Emergency credit proved necessary. Emergency seed loans were made by Federal or State Governments, and the War Finance Corporation was authorized to permit advances for agricultural purposes. Resort to emergency credit emphasized the inadequacy of the commercial-banking system.

The Intermediate Credit System was formed under the Agricultural Credit Act (1923) to provide production and marketing credit for periods longer than those ordinarily supplied by commercial banks. It was intended to supplement and strengthen the commercial banks and not to supersede them. There are twelve Intermediate Credit Banks with districts corresponding to those of the Federal Land Banks. Each has a capital stock of \$5,000,000 subscribed by the Federal Treasury. Funds with which to make advances are obtained from capital stock and sale of collateral trust debentures, which may be issued to ten times the unimpaired capital and surplus of each bank. The banks are jointly liable for all debentures issued. The debentures are tax-exempt and find a ready market. Advances are made either direct to Co-operative Marketing associations or on the security of warehouse receipts or shipping documents covering staple agricultural products, or in the form of discounts. The rate charged on direct loans to these associations may not exceed by more than one per cent the interest rate at which the last issue of debentures was sold. As the debentures sell well, the banks have been able to make direct advances to Co-operative Marketing associations at rates between 4½ and 5½%.

Federal Intermediate Credit Banks may discount for local banks, Live Stock Loan companies, and other credit agencies, agricultural paper maturing in from six months to three years. The discount rate may not exceed by more than one per cent the rate paid on the last debentures sold. On the other hand, institutions using the Intermediate Credit Banks may not charge a rate that exceeds the discount rate by more than 1½% except by special ruling of the Federal Farm Loan Board.

The Act provides for Agricultural Credit corporations in regions where established credit institutions do not provide the necessary facilities. Such corporations may be formed by any group of citizens under State laws, with a maximum paid-up capital stock of \$10,000. They may rediscount agricultural paper with the Intermediate Credit Bank up to ten times their capital and surplus.

Several types of credit corporations have been organized.

There is provision for National Agricultural Credits corporations with a minimum capital of \$250,000. These are privately operated competitors of the Federal Intermediate Credit Banks, and operate under the supervision of the Comptroller of the Currency. Few National Agricultural Credit corporations have been organized, partly because of the high initial capital and rigid reserve requirements.

The direct loans of the Intermediate Credit System outstanding Dec. 31, 1927, were \$31,990,596.65. The influence of such loans is not to be measured by their volume alone; availability of such funds for co-operatives has encouraged private banking institutions to advance more liberally to co-operatives. Rediscunts of the system as of the same date totalled \$43,923,940.42. Most of these advances were to Agricultural Credit corporations and Live Stock Loan companies.

The Intermediate Credit System has not been in existence long enough fully to demonstrate its place in our rural credit system. The best methods of organizing and operating Agricultural Credit corporations still remain to be found. While State and national banks do not yet use the system, experience probably will show how it may be used in handling their longer-term agricultural paper. The greatest influence of the system will probably be in regions now lacking adequate banking resources, and where the cost of credit is unduly high.

AGRICULTURAL ECONOMICS. From the earliest times the art of husbandry has been not only the preoccupation of those who practise it, but also the subject of innumerable treatises explaining its principles and suggesting methods for its improvement. Within the last century the application of the results of scientific investigation to the cultivation of the soil has been expounded with ever-increasing voluminousness. But the consideration of farming as a business has been only recently recognized as a subject for systematic study. Farming in many countries is a means of subsistence, and can only be described as a business in a limited sense, but commercial agriculture is yearly becoming more widespread and more important.

Agricultural economics may be defined as the special application of the general principles of economics to the special conditions of the production and sale of agricultural products. It comprises therefore the consideration of the factors of production, the cost of production, and the disposal of the produce. It is not concerned directly with the technique of farming but it assumes that experience, skill and energy in the use of the land will not suffice for commercial success without knowledge of the economic as well as the practical details of farm management. The subject of agricultural economics includes within its scope many subjects which are, so to speak, self-contained, such as farm accounts, farm valuations, and agricultural co-operation, which are considered under their separate headings.

In the United States, the systematic study of agricultural economics forms a part of the curriculum of State universities and agricultural colleges and of the larger endowed universities. A well equipped bureau of the U.S. Department of Agriculture has done admirable work in research and in expounding and popularizing the subject. Its work covers a wide range of subjects: Land problems; agricultural finance, including credit, insurance and taxation as they affect agriculture; farm management and cost of production; statistical and historical research on a wide range of subjects; co-operative marketing; foreign competition and demand, as affecting agriculture; and other subjects. The State agricultural experiment stations, supported by State and Federal funds, conduct research on various phases of agricultural economics. In 1925 Congress passed the Purnell Act, under which

Federal support to each State for agricultural research will reach the maximum of \$60,000 a year in 1929, in addition to the \$30,000 available under earlier acts of Congress. The Purnell Act specifies that a part of the funds shall be used for research in agricultural economics, home economics and rural sociology. Among the privately supported institutions conducting research in this field are: The Institute for Research in Land and Public Utility Economics (Northwestern university) established under the direction of Dr. Richard T. Ely, and the Food Research institute of Leland Stanford university. The field of research in agricultural economics in the U.S. may be divided into three general groups of problems: (1) Problems which may be dealt with mainly by individual effort. These include farm management, embodying the organization of the factors of production on the individual farm and the adjustment of farming according to changes in costs of production and in prices of farm products. (2) Problems that may be solved by joint effort of farmers acting through co-operative organizations or other associations. In 1926 Congress created the Division of Agricultural Co-operation in the Bureau of Agricultural Economics, to conduct research and to render services to farmers on all phases of co-operation. Legislation to remove legal obstacles to co-operative organizations, notably the Capper-Volstead Act, has been passed in recent years. (3) Economic problems of agriculture that may be dealt with by governmental policy expressed through laws and public institutions. This group includes agricultural credit, land policies, public expenditures and taxation as they affect agriculture, regulation of transportation systems in their relation to agriculture, tariff problems and other phases of public policy. In addition to these groups of problems, research is also concerned with the functions of private agencies in merchandising, transporting and processing farm products.

In Great Britain the subject was taken up by the agricultural department (Board of Agriculture and Fisheries), but with very limited resources, shortly before the war, and with assistance from the Development Fund, and from the University of Oxford an institute of agricultural economics was established at Oxford. Its activities were at first mainly directed to the improvement of farm accounts, especially by the adoption of the cost accounting system, but as further resources became available its scope was widened and it has made a number of important investigations into the economic conditions of different areas. At Cambridge, also, the farm economics branch of the department of agriculture of the university has, more recently, vigorously taken up the work. Throughout the country an agricultural economist is now a recognized and important member of the staff of all institutions which are concerned in the development of agricultural education.

Factors of Production.—The primary factors of agricultural production are land, labour and capital.

The utility of land for producing crops depends on soil, climate, situation and aspect. Nearly all kinds of soil are actually or potentially fertile, although over large areas the fertility is dormant by reason of the lack of some constituent essential to plant growth. The deficient constituent is frequently water, but in many cases it is some ingredient which may be identified by chemical analysis and conceivably supplied by man. Climate is in a large degree a matter of situation. The tropics and the temperate zone comprise all land suitable for productive use, but advantages of situation depend not only on latitude but also on altitude. By aspect is meant in a hilly country the relation of the land to the sun, as, for example, whether it lies on a northern or on a southern slope.

For the purpose of agricultural use the farmer must have exclusive control of the land. If he does not acquire its ownership the form and terms of tenure will materially affect the economic possibilities of his enterprise. From an economic point of view, holdings are of three classes: viz. (1) those which are occupied by persons who do not depend on them for their livelihood; (2) those which are cultivated for subsistence by the occupier and his family without extraneous labour (sometimes termed "family farms"); and (3) those on which hired labour is regularly employed. It is with the third class "commercial farms," that the subject of agricultural economics is mainly concerned.

In considering the capital employed in agricultural production, that which is invested in the acquisition of the land may be disregarded. In many new countries free grants of land are made to settlers. In countries where agriculture has been long established, the capital value of a holding includes its equipment as a farm and the proportion which represents the bare land may be comparatively small. The capital employed in working a farm in Great Britain, where holdings are more commonly rented than owned by the occupiers, is termed "tenant's capital." It consists of the amount invested in machinery, implements and other movable equipment of the farm, in the horses and other live stock, and in the seed, fertilizers and labour for growing crops. The amount varies greatly, but on an average farm in Great Britain it probably ranges from about £10 to £12 per acre. On specialized farms, such as those devoted to fruit or vegetables, the amount may be £40 or even more per acre.

Labour as a factor of production includes not only the manual work and skill of hired labourers but also that of the farmer, whether employing labourers or not (*see AGRICULTURAL LABOURER*), and animal and mechanical energy applied to the processes of the farm partly in supplement of, and partly in substitution for, human energy. Oxen are the most widely used animals for farm work, but in Great Britain they have been replaced by horses during the last 200 years, although they were still in use in some districts up to the latter part of the 19th century. In those countries, such as the United States and the Dominions, where systematic agriculture has been recently established, horses were from the first generally used. Mechanical labour includes not only motive power, such as steam or other engines, but also machines and implements such as thrashers, reapers, haymakers, ploughs, etc., which either economize human energy or enable it to be more effectively applied in the operations of the farm.

Costs of production may be divided into two classes, viz., fixed charges and current expenses. The ordinary tenant farmer regards rent as ranking foremost in his costs of production, but strictly speaking only that part of it which represents interest on capital spent in equipping the farm can be so described. The interest on capital expended on equipment, whether permanent or temporary, is a fixed charge and so also are rates and (where they exist) land-tax and tithe-rent charges. Current expenses include outlay on seed, fertilizers and feeding stuffs, fuel for engines and repairs. The payment of wages is a current expense, but it might also be described as a fixed charge, though of a variable amount. Where the occupier himself cultivates his holding it is evident that the remuneration of his labour is a fixed charge without which there would be no produce from the land. Where he employs labour his "wages of management," and such other wages as are necessary for production, may similarly be regarded as a fixed charge on the land. In all farming operations the turnover is slow, as compared with other forms of productive enterprise. This "economic lag" has been investigated on the basis of the accounts of two farms by Mr. Dampier Whetham. It was found to be greatest in the case of cattle, where the average "lag" was 18 months, and least in the case of poultry and eggs, where it was three months.

Disposal of Produce.—The simplest method by which the cultivator of the soil can dispose of its products is to consume them in his own household, but even in "subsistence" or "family" farming there is usually some surplus for sale. There are three methods by which farm products may be sold: viz., (1) by direct sale to the consumer, (2) through intermediaries, (3) by co-operative association. Direct sale is usually adopted by "small scale" producers and for "minor" products, such as eggs, poultry, fruit and vegetables, but "large scale" producers may also adopt the method by opening a shop in an adjacent town or establishing a "milk round." Direct sale of fat stock by farmers to butchers was very common in Great Britain, but it is now generally replaced by the auction system. The bulk of agricultural produce is sold through intermediaries. The commercial organization of the distribution of the main products is elaborate. Where the products are the subject of international trade, as in the case, notably, of wheat and meat, the system by which they are collected, shipped and distributed is remarkably efficient. But where

the producer, as in Great Britain, sells his products in his own country, the distributive system is, from his point of view, unsatisfactory. The difference between an export and an inland trade accounts in a large degree for the difference in the machinery of distribution. For an export trade collection of bulk consignments at fixed points for shipment is imperative. The producer has no other outlet except under these conditions. In an internal trade producers usually have a choice of alternative markets, and are not compelled to adopt a uniform method of sale. The result is that imported produce, with its highly efficient distributive organization, tends more and more to dominate the wholesale trade, and the home producer finds that his natural advantages of proximity to markets, and, generally, of superior quality, are not sufficient to enable him to maintain his position. The adoption by British farmers of a system of "orderly," or organized, marketing has been vigorously advocated (*see AGRICULTURAL CO-OPERATION*). The term "marketing" is now commonly used as synonymous with sale, but it perpetuates the fact that in old countries the sale of commodities, and particularly of food, was permissible only in duly constituted markets. Many of these remain, but in Great Britain they have long lost the monopoly which they once possessed, although market tolls and regulations still survive in many towns. For information on various American aspects and applications of this subject *see AGRICULTURE: Agriculture in the United States*. *See also AGRICULTURAL CREDIT and AGRICULTURAL INSURANCE*.

Hawthorne, *The Family Living from the Home* (1925); *Farm Living and Farm Life*, a symposium (Chicago, 1927). Bulletins and other publications by the United States Department of Agriculture and by the State experiment stations cover a wide range of topics in this field. *Journal of Farm Economics*, a quarterly published by the American Farm Economics Association, carries articles on various phases of the subject and reviews of books. (R. H. R.)

AGRICULTURAL EDUCATION. Though agriculture is the oldest and greatest of industries, agricultural education in any organized form is among the recent activities of modern states. In Great Britain, or at least in England and Wales, it may be said to go back only to 1890. It would be untrue, however, to say that before then nothing was done. Chairs of agriculture and rural economy were founded at Edinburgh in 1790 and at Oxford in 1796; the Royal Agricultural college at Cirencester was established in 1840. But agricultural education provided in universities or colleges was beyond the reach of the bulk of the agricultural population. Little or nothing was offered to the children of farmers, smallholders, and labourers until nearly the end of last century. In 1890, however, the Local Taxation (Customs and Excise) Act placed at the disposal of county councils a sum of money (popularly known as the "Whiskey Money," because it was derived from an increase of the taxation on spirits which was originally destined for another purpose), amounting roughly to £750,000 a year, and authorized them to apply it to purposes of technical instruction, including instruction in agriculture. From

1890 onwards there was a considerable, if slow, increase both of the higher education provided by university departments of agriculture and agricultural colleges, and of instruction provided by county councils. By 1912 the State was granting £19,000 a year for higher education, and the English and Welsh county councils were spending £70,000 a year on the more elementary instruction. The World War stopped the development of plans already prepared for further expansion on a relatively large scale.

Post-War Development.—The present system, though it follows pre-war lines in its organization, is largely the creation of the years since 1918. It falls into two main parts; the university departments of agriculture and agricultural colleges, whose distinctive mark is that they provide a long course, two years at least, usually three, leading to a diploma or degree; and the education provided by county councils, which is essentially an education of short courses intended for the boy or girl who is already working on the land and proposes to return to it.

Higher agricultural education in England and Wales (excluding veterinary education) is provided at 14 centres, of which seven are departments or schools of universities, and the other seven are agricultural colleges, each possessing its own governing body, and not forming an integral part of a university. Eleven of these institutions (all except the Royal Agricultural College at Cirencester and the two women's colleges at Swanley, in Kent, and Studley, in Warwickshire), discharge an important function outside the actual teaching of students. Each is an "Advisory centre" for a group of counties forming its "Province"; it is provided with specialists in the more important branches of science bearing on agriculture, such as chemistry and entomology, who supplement the more general advice provided for farmers by the technical staffs of county councils, and it acts as a unifying and co-ordinating influence for the experimental and advisory work of county councils. All the 14 institutions are recognized and aided by the State. The cost to the student varies considerably between the two Welsh colleges (Aberystwyth and Bangor) at one end of the scale and Oxford or Cambridge at the other end.

Education of a less elaborate character is provided by county councils; in some counties by means of a farm institute (a simpler and smaller agricultural college, usually possessing residential accommodation and a farm attached), in practically all counties through organized classes, held at no special institution, or through discussion clubs, evening lectures, and similar less systematic methods. In 1927 there were 16 farm institutes, four in Wales (including Monmouthshire) and the remainder in England, all but one supported and governed by county councils. On the average they can accommodate 40 students each; the fees for board, lodging, and tuition vary between 17s. 6d. a week for students coming from the county which supports a particular institute to £2. 10s. 0d. a week for other students. The main course at a farm institute is normally a six months' winter course in practical agriculture, extending from October to March, and designed for young people, from the age of 16 upwards, who have been working on the land and are going straight back to it. During the summer months the institute is used for courses in dairying, poultry keeping, and other special subjects. The great majority of county councils, however, do not possess farm institutes, but attempt to take agricultural education to the land-worker by such means as the "Organized day course" (a continuous course of instruction held at regular times, usually one day a week, in any town or village where there is a demand for it, and extending over several weeks or perhaps months), evening classes, travelling dairy schools, courses for instruction in manual processes (ploughing, hedging, ditching, milking, and the like), and lectures or demonstrations.

In 1925-26 the cost of the education provided by county councils in England and Wales was £312,000, of which the Government provided a fraction over two-thirds and county rates the remainder. One other activity deserves mention. In 1922 the Government started a scheme of scholarships in agriculture for the sons and daughters of agricultural workmen and of other rural workers in a similar economic position. Under this scheme approximately 100 scholarships are awarded every year, of which

the great majority are short-term scholarships to farm institutes. The cost is £20,000 a year.

In Scotland, agricultural education has followed a rather different course, though it started on the same lines. The organization is not divided between universities and colleges on the one side and county councils on the other; the colleges control and direct the whole system. Apart from the small sums received as fees, the whole cost is met by grants from the State, which in 1925-26 amounted to £75,000. But in the education given, as distinct from the organization for giving it, the Scottish system resembles the English. The three colleges in alliance with their respective universities provide long courses (three winter sessions) for the university degree or college diploma; they take the place of the English farm institutes by including in their curricula short courses for farming; and through the appointment of organizers resident in the counties they conduct extension work similar to that done in England and Wales by the staffs of county councils. Two special institutions should be mentioned: the Kilmarnock dairy school and the Craibstone School of Domestic Economy for Women, the former associated with the Glasgow college and the latter with Aberdeen.

Other Systems.—Broadly speaking, and with considerable variations due to differences of national character and environment, Continental systems tend to fall into the main divisions already enumerated, of two or three years at universities or agricultural colleges; in the second place, there are short courses of a few weeks or months in the dead season, or of a year at most, at a residential institution—sometimes a college, more usually a farm institute or farm school; thirdly, miscellaneous courses, lectures, and demonstrations given by peripatetic instructors who endeavour to bring technical education to the farmer's door, or at least to his town or village. But there are one or two features of foreign systems which ought to be mentioned, if only by way of contrast to the British system.

Of these the most striking is, perhaps, the large part taken in Germany, Denmark, Sweden, and in fact nearly all over the continent of Europe, by voluntary societies and associations; in Denmark, for instance, agricultural societies own and manage many of the Folk high schools and support many "agricultural counsellors"—experts who combine teaching, lecturing, and advisory functions. But the Folk high schools of Denmark are notable not merely as an example of voluntary effort; they are a great and successful attempt to add a finish to the education of the adult land-worker by giving him or her a six to nine months' course, not entirely agricultural and sometimes not agricultural at all, at a residential institution. In Belgium, a country of small-holders, there is a highly developed system of instruction for women and girls in a combination of practical agriculture and rural domestic economy; the system centres in the national institution at Laeken. In Sweden also (besides the usual agricultural colleges, agricultural schools, and farmers' sons' schools, the last providing a three months' theoretical course for young men, usually about the age of 22) there are something like 40 schools of agricultural economy for women.

Changes in the British System.—From 1924 or thereabouts two movements affecting agricultural education have gained prominence. The first is the movement for imparting into the ordinary subjects of instruction taught at rural elementary and secondary schools what is known as a "rural bias"—e.g., arithmetic may be taught through simple farm accounts, or geography with at least some reference to the physical characteristics of the district in which the school is situated. Provided it does not degenerate into a premature attempt at vocational training, there is everything to be said in favour of such a change.

The second change is a change of emphasis in the subjects usually taught in agricultural institutions and courses. Hitherto syllabuses of instruction have tended to be dominated by science, or rather sciences—chemistry, physics, botany. A school of thought has arisen which starts from the fact that the farmer is not only a grower of crops, a producer of eggs or milk, a breeder of stock, but also a manager of labour, a buyer of goods, and a seller of products—in the ordinary phrase, a business-man. There

is consequently a steady pressure towards modifying courses of instruction, particularly the short winter courses, by giving a larger place to such subjects as accounts (the foundation of business), the management of labour, and the elements of marketing technique. There can be little doubt that this side of agricultural education has been relatively neglected; but the teaching of management is not easy.

Defects in the British System.—But though these changes may be beneficial, the British system still reveals several notable defects. First, it is far too small, not, perhaps, for the demands which are actually made on it, but for the demands which ought to be made. In the second place, the larger part of the English and Welsh system—the part organized and directed by county councils—is “patchy.” There is no power to compel county councils to supply even the barest modicum of agricultural instruction, and accordingly the provision made for it in a county varies with the character and finances of the county council and its electorate. Thirdly, provision for the residential education of adults—one of the most marked and successful features of Continental systems—is noticeably absent. Lastly, provision for instruction in manual processes and in the handling of machinery, though not absent, is not so common as it should be.

Progress Being Made.—Some of these defects are being slowly remedied. In spite of financial exigencies, college and county education does progress and grow; and, best of all signs, authorities are agreed that in the last 20 or 30 years there has been a remarkable change of attitude on the part of the agricultural community. Farmers welcome the assistance of college and county staffs; and a first attempt has been made, through private enterprise, to provide at Avoncroft, near Evesham, an institution very similar to the Folk high school of Denmark for adult land-workers. If that experiment proves a success, it may be the beginning of a new era. Moreover, the education of women and girls has recently been investigated by a strong committee, who have surveyed the whole field; and the Ministry of Agriculture has put before county councils a detailed scheme for extending instruction in manual processes. In 1925–26 the number attending such instruction rose to 1,900—a number which, however small in itself, was at least an increase of 50% on the previous year.

BIBLIOGRAPHY.—Numerous papers on different aspects of the subject are scattered about in the *Journal of the Ministry of Agriculture*, the *Proceedings of the Royal Agricultural Society*, the *Proceedings of the British Association*, and similar volumes.

(1) *Reports of Committees.*—Committee on Agricultural Education in England and Wales, 1908 (Cmd. 4,206 of 1908: Stationery Office, London). Committee on Agricultural Education and Research in Scotland, 1924 (Stationery Office, Edinburgh). These two reports contain a general survey of the British and foreign systems.

(2) *Departmental Reports.*—Reports of the Intelligence department of the Ministry of Agriculture and Fisheries for the years 1919–21, 1921–24, and 1924–26. All three published by the Stationery Office, London. Annual Reports of the Board of Agriculture for Scotland (Report for 1926, Cmd. 2,854 of 1927, Stationery Office, Edinburgh). These reports give the facts and figures in detail. The first mentioned contains a statement of Government policy in agricultural education.

Leaflet No. 197 of the Ministry of Agriculture and Fisheries, *Agricultural Education in England and Wales*, gives a list of existing institutions, together with the courses provided, fees, and similar details. Board of Education Pamphlet No. 46, 1926, *Rural Life*, gives a survey of what has been done in England to adapt school courses to the needs of rural areas.

(3) *Other Papers.*—*Memorandum on the Reconstruction of Agricultural Education in England and Wales*, published by the Agricultural Education Association (1919). Sir A. D. Hall, “Agricultural Education 1890–1926,” in the *Scottish Journal of Agriculture*, vol. x. No. 2. pp. 135–143 (Stationery Office, Edinburgh). (H. E. D.)

IN THE UNITED STATES

Agricultural education in the United States finds its beginnings in the striving of individual land-owners toward higher levels of production. This created interest and discussion in agricultural communities, induced the making of tests, trials and observations, pointed to the advantages of concerted action, and slowly but steadily laid the foundation on which present-day educational machinery was built.

Agricultural Schools.—Among the early attempts to provide agricultural instruction in schools of less than college grade

the following may be noted: In 1821 the State legislature of Maine granted to Robert Hallowell Gardiner an annual appropriation of \$1,000 for the maintenance of an institute for agricultural and mechanic arts. The Gardiner Lyceum was opened at Gardiner, Me., in 1823. It employed a professor of agriculture, maintained a farm and offered short winter courses in agriculture. An agricultural school was founded at Derby, Conn., in 1826. So-called manual labour schools were established in New York State in the period 1825–40. They laid stress, in their curricula, on vocational training in agriculture and the industries. In 1845–50 several agricultural schools were founded, through private initiative, in New York and Connecticut. After the middle of the 19th century conditions became more propitious for the teaching of agriculture in elementary and secondary schools. A period of agitation was followed by the establishment of an agricultural high school at the University of Minnesota (1888). District and county agricultural schools were created a few years later, among them the agricultural schools in the nine congressional districts of Alabama. By 1898 there had been established ten agricultural high schools. In 1909, there were 60 separate agricultural high schools. Agricultural courses were then being offered in 346 other high schools. Several States, among them Massachusetts (1911), New York (1913), Pennsylvania (1913), New Jersey (1913) and Indiana (1913) had established definite systems of vocational agricultural education. It is estimated that in 1912–13 there were about 2,300 State agricultural schools, district agricultural schools, agricultural departments of high schools and ordinary schools that maintained systematic instruction in agriculture.

The Smith-Hughes Vocational Education Act (1917) provides Federal aid for vocational training, including the teaching of agriculture and home economics in secondary schools. Since the passage of this Act many vocational agricultural schools, as well as agricultural departments of general high schools, have been established in the several States. Of the 11,561 rural high schools, 3,339 or 29% maintained vocational agricultural departments in 1927. They had an enrolment of 129,032 students. In that year there was available for the support of vocational agricultural education nearly \$7,500,000, compared with about \$740,000 in 1918. Aside from these institutions, agriculture is being taught in some of the private high schools, in normal schools, and in special schools for negroes and Indians. It may be noted, further, that many States have special laws which concern the teaching of agriculture in elementary rural schools.

Agricultural Colleges.—Simeon de Witt, surveyor-general of New York, published, in 1819, a pamphlet entitled *Considerations on the Necessity of Establishing an Agricultural College, and Having More of the Children of Wealthy Citizens Educated for the Profession of Farming*. A State agricultural college was established in New York in 1853. The oldest surviving state agricultural college is that of Michigan (1857). Similar colleges were established in Pennsylvania and Maryland (1859) and the incorporation of agricultural colleges authorized in Iowa and Minnesota (1858). The Federal Land Grant Act (also called the first Morrill Act) was passed in 1862. It created a group of State institutions of higher learning, known as the land grant colleges and universities (*q.v.*). This legislation was far-reaching in its effects on the social and economic development of the country. The second Morrill Act (1890) and the Nelson amendment of the Morrill Act (1907) provided additional funds for the State colleges.

The State colleges and universities are intimately associated with the U.S. Department of Agriculture. This had its inception in the collection and distribution of seeds and plants by the Patent Office in 1839. The service was expanded to furnish information on various agricultural topics. In 1862 the Department of Agriculture was organized as such and in 1889 its head became a member of the President's cabinet. When the Hatch Act was passed (1887) funds were made available for the establishment of experiment stations as departments of the State colleges. Prior to that, State agricultural experiment stations had been established in Connecticut (1875), California (1877), North Carolina (1877), New York (1879 and 1882), New Jersey (1880), Ohio, Tennes-

see and Massachusetts (1882), Alabama and Wisconsin (1883), Nebraska (1884), and Michigan, Indiana, Kentucky, Maine and Minnesota (1885). A private sugar-planter's experiment station was established in Louisiana in 1885, and State stations in Louisiana, Vermont and New Hampshire in 1886.

In keeping with the provisions of the Hatch Act, an office of experiment stations was organized in the Department of Agriculture for the purpose of maintaining contracts with the stations. Subsequent legislation referred to as the Adams (1906) and Purnell (1925) Acts augmented the income of the stations, established better correlation of research on a regional and national basis and encouraged co-operation among the stations themselves and with the Department of Agriculture. The stations are primarily research institutions. As such they are maintaining many hundreds of research projects of direct significance to agriculture and the farm home, and creating a vast body of knowledge from which facts and generalizations are being drawn for the benefit of resident instruction and of extension teaching.

The Smith-Lever Act was passed in 1914. It represents a national scheme of extension teaching in agriculture and home economics and is the culmination of a long series of local, State, regional and national efforts to stimulate agricultural progress by bringing technical and general information to the farm and farm home. The antecedents of the Smith-Lever Act include the almanacs, agricultural journals and newspapers, agricultural societies, boards of agriculture, farmers' institutes and demonstrations and lectures by public-spirited individuals. The Act provides for county agents, home demonstration agents, club leaders and extension specialists. It makes the Department of Agriculture responsible for co-ordinating and supervising the extension activities in the several States.

The agricultural teaching, research and extension of the land grant colleges and universities is being generously supported by the local, State and Federal Governments. In 1928, the Federal Government was appropriating about \$7,000,000 for the support of agricultural extension, while the States, counties, farm organizations and individuals were expending for the same purpose about \$13,000,000.

See A. C. True, *Education and Research in Agriculture and Home Economics in the United States* (1922); C. B. Smith, *Co-operative Extension Work, 1924, with ten years' Review* (1926); Walter J. Greenleaf, "Land Grant Colleges," Bureau of Education Bulletin, No. 37 (1927). (J. G. L.)

AGRICULTURAL ENGINEERING is that specialized branch of engineering which deals with agriculture; it seeks scientifically to direct the forces and facts of nature to the advantage of the farmer.

The distinction between agricultural and the other branches of engineering may be illustrated by examples—irrigation and drainage, for instance. The agricultural engineer concedes to the civil engineer the problems incident to the extensive storage and arterial distribution of irrigation water, and to the design and construction of large community drainage outlets. The benefits of such works, however, are realized only to the extent that contact is made with individual farms. It is at this point that the agricultural engineer claims jurisdiction. In irrigation, the water made available to the farm must be economically distributed and applied with reference to the topography, the character of the soil and the crops to be irrigated. In drainage, ditches and underdrains must be planned with regard for the peculiarities of each field and of the use to be made of the land. Again, although the agricultural engineer does not ordinarily concern himself with the commercial design and the manufacture of farming implements, he does claim a share in securing not only the best use of such equipment as is at hand, but also better designed equipment.

Agricultural engineering is the outgrowth of a realization that many of the farmers' problems lie within the field of engineering and therefore should be attacked from that point of view. It is generally recognized that the marked advance in agriculture since 1850 has been due in large measure to improved engineering practice. Thus the development of farm-land from its primal state by clearing, the control of erosion by terraces, the disposal of surplus water and the acquiring and regulating of the water needed for

plant growth and for human and animal consumption, the erection of structures of all types, with their problems of light, heat, ventilation, etc., and the best use and design for the machinery and implements used in farm operations and transportation, as well as the sources of the power which operates them, are all problems for the agricultural engineer. This is common sense, and in the United States this view is generally accepted. In England and Continental Europe, however, the scope of agricultural engineering is less defined, the tendency being rather to give practical recognition to two distinct divisions of the science, dealing respectively with the mechanical phases (implements, machinery and power) and those of the soil (irrigation, drainage, erosion control, etc.).

In the United States in 1928 12 State agricultural colleges maintained courses leading to a degree in agricultural engineering, while several others, though they did not grant degrees, offered courses that constituted a virtual recognition of the science. Such German universities as are equipped to give instruction recognize agricultural engineering by offering a doctor's degree. Up to the present time agricultural engineering has been looked upon chiefly as one of the many agencies through which, by research and dissemination of information, governmental and educational institutions are striving to improve the condition of the farmer. One does not, therefore, often meet with the practising or consulting agricultural engineer. (See also articles on LAND RECLAMATION; ELECTRICAL POWER IN AGRICULTURE; DRAINAGE OF LAND; etc.)

BIBLIOGRAPHY.—The bibliography of agricultural engineering consists chiefly of the publications dealing with its various component subjects. See Bulletins of the U.S. Department of Agriculture and those of the State agricultural experiment stations and extension services; publications of the American Society of Agricultural Engineers (St. Joseph, Mich.); Committee on the Relation of Electricity to Agriculture (Chicago); Institute of Agricultural Engineering (Oxford university); the Royal Agricultural Society of England (London); Deutsche Kulturtechnische Gesellschaft (Breslau); Konferenz Schweizerischer beamter Kulturingenieure (Lucerne). See also G. S. Mitchell, *Handbook of Land Drainage* (1898); J. B. Davidson and L. W. Chase, *Farm Machinery and Farm Motors* (1908); P. McConnell, *Farm Equipment, Buildings and Machinery* (1910); C. G. Elliott, *Practical Farm Drainage* (1912); Sir Hanbury Brown, *Irrigation—its Principles and Practice as a Branch of Engineering* (1912); C. G. Elliott, *Engineering for Land Drainage* (1913); R. P. Teele, *Irrigation in the United States* (1915); B. A. Etchevery, *Use of Irrigation Water and Irrigation Practice* (1915); J. B. Davidson, *Agricultural Engineering* (St. Paul, 1917); H. C. Ramsower, *Equipment for the Farm and Farmstead* (Chicago, 1917); F. A. Wirt, *A Laboratory Manual in Farm Machinery* (1917); A. P. Davis and H. M. Wilson, *Irrigation Engineering* (1919); J. B. Bond, *Farm Implements and Machinery* (1923); F. N. G. Kranick, *Farm Equipment for Mechanical Power* (1923); John T. Stewart, *Engineering on the Farm* (Chicago, 1923); D. N. McHardy, *Modern Farm Machinery* (1924); G. W. Pickels, *Drainage and Flood Control Engineering* (1925); R. H. Smith, *Agricultural Mechanics* (1925). (H. H. B.)

AGRICULTURAL GANGS, groups of women, girls and boys organized by an independent gang-master, under whose supervision they execute agricultural piece-work for farmers in certain parts of England. The evils of this system were so great as to lead to the passing of the Agricultural Gangs Act 1867, forbidding the employment of any child under eight years old, and of any female under a male gang-master unless a female licensed to act as gang-mistress were also present. Gang-masters must be licensed by two justices, and may not hold a liquor licence. Later legislation made more stringent the regulations under which children are employed in agricultural gangs. By the Elementary Education Act 1876, repealing and re-enacting the principal provisions of the Agricultural (Children) Act of 1873, employment of all children under 11 was forbidden and restricted under 13. Now, by the Education act of 1921, it is forbidden under 12 and restricted under 14.

AGRICULTURAL INSURANCE. The risks against which farmers have to provide are those incurred in growing, harvesting and storing crops; animal diseases; condemnation of carcasses in slaughter-houses; and those risks commonly covered by ordinary life, accident and property insurance. The nature of the risks to which farming is exposed vary between one country and another according to its situation and climate. Thus losses from wind-storms are more common in North America than in many countries of Europe (it has been stated that between 1916

and 1923, 752 tornadoes occurred in the United States—an average of 94 annually); in Great Britain animal diseases, and in Scandinavia forest fires, are more important risks, while in Canada damage by hail causes heavy losses to farmers.

Insurance against these risks may be carried out either through ordinary joint-stock insurance companies, or through farmers' mutual insurance societies. Both methods are used, but the latter is held to have certain advantages. Local mutual insurance societies operating in a small area frequently cover the risk by re-insurance.

In Great Britain there is very little co-operative insurance. A number of joint-stock companies specialize in livestock insurance in addition to covering ordinary accident and fire risks. There appears, however, to be little inclination on the part of British farmers to take advantage of these facilities except in the case of pedigree cattle and other valuable stock. The number of registered mutual insurance societies has declined since 1913, but several unregistered cow and pig clubs exist for the insurance of their members' livestock. Under the Diseases of Animals Act 1894 compensation is payable by the State in case of animals slaughtered in consequence of foot and mouth disease, swine fever, and other diseases. In other countries agricultural insurance has made considerably more progress.

The insurance of crops after harvest is a relatively simple matter, and the risk (mainly a fire risk) is often covered by ordinary joint-stock insurance companies. The insurance of growing crops is a more specialized business. Under this head the most successful development is insurance against damage by hail. In the United States, 43 joint-stock fire insurance companies, 41 mutual companies and four State insurance departments carried hail risks estimated in 1919 at \$560,000,000. Since 1919 the amount of hail insurance written in the United States has declined. Total premiums received on hail insurance, which in 1919 amounted to \$28,000,000, had dropped by 1923 to \$18,000,000. In Canada, the Hail Insurance District of Alberta was formed under the Municipal Hail Insurance act of 1918, having in 1919 67 municipal districts. Hail taxes are paid by ratepayers to the municipal districts which in turn pay to the municipal board. The total risk borne by the Hail Insurance Board for the four years 1919-22 amounted to \$72,000,000. In Saskatchewan the Municipal Hail Insurance Association carried an insurance of about \$25,000,000 in 1921 and 1922.

Hail Insurance in Europe has been developed to a less degree, but organizations to cover this risk are to be found in Germany, Austria, Denmark, Switzerland, France, Spain, Italy and elsewhere. In France 29 mutual societies existed for this purpose in 1921, and Italy had 51 societies in 1922. Some progress has been made, particularly in the United States, in the provision of frost insurance.

Farmers in aggregate have large sums invested in livestock which is liable to suffer loss by disease and other causes. Insurance against these risks through mutual insurance societies or otherwise has made greater progress in certain European countries than elsewhere, although the United States has some 30 mutual livestock insurance companies. France provides perhaps the leading example of European livestock insurance; its development has depended partly on state subsidies. Out of the 14,896 subsidised co-operative insurance and re-insurance societies in France in 1921, over 10,000 were societies for the livestock insurance, and 78 for re-insurance.

Co-operative insurance in Germany has not made progress comparable with that of other forms of agricultural co-operation. Only a small fraction of the livestock in the country is covered by insurance. In certain States, notably Baden and Bavaria, cattle insurance has received State assistance. Insurance of carcasses against condemnation by the sanitary authorities has also been adopted on a small scale.

Fire insurance is almost universally undertaken by the ordinary joint-stock companies but in some countries, notably the United States, it has also been largely developed on a co-operative basis. Indeed mutual fire insurance is one of the most successful as well as the oldest co-operative services which have grown up in

that country, where, in 1926, there were about 2,000 farmers' mutual fire insurance companies carrying risks amounting to over \$10,000,000,000. At the close of 1926 well over half of the total farm property of the United States insurable against fire was insured in farmers' mutual companies.

See *International Review of Agricultural Economics*. (R. E.)

AGRICULTURAL LABOURER. An agricultural labourer is a person, male or female, employed by an occupier of agricultural land. In America and some other countries the term "hired man" is generally used. In Scotland the term "farm-servant" is equivalent to that of "agricultural labourer" in England where the alternative term "farm worker" has recently come also into common usage. Conditions of employment vary widely. The contract of service may be by the day, the week, the month, the half-year, or the year. Remuneration for services may be wholly in cash, or partly in cash and partly in kind. In Scotland, in the greater part of Wales and in the north of England the majority of agricultural labourers live in their employer's house or in quarters specially provided for them on the farm. They receive wages in addition and in England and Wales the amount which may be reckoned in respect of board and lodging as part payment of wages is fixed. Where the engagement is on such terms the contract of service is usually for a year, or, in some cases, for a half-year. Over the greater part of England the ordinary contract of service is by the week at a fixed cash wage. (*See AGRICULTURAL WAGES.*)

In addition to agricultural labourers permanently employed there are large numbers of men and women who are employed only for short periods to assist in particular operations, such as corn-harvesting, fruit-picking, hop-picking, etc. In countries such as Canada where wheat and other corn-crops are grown on an extensive scale it is usual to engage additional men for the period of harvest. In England a large number of men and women are engaged in the districts where hops are grown for picking the crop, and in some of the districts where fruit and vegetables are cultivated a similar practice prevails. Persons so employed are often not agricultural labourers in the strict sense but are in many cases townfolk unskilled in farm work.

Enumeration.—Returns collected by the Ministry of Agriculture, from all occupiers of agricultural holdings in England and Wales show that there were, in June, 1926, 794,899 agricultural labourers employed, of whom 654,361 were classified as "regular workers" and 140,538 as "casual workers." The term casual worker has a wide significance. It includes not only those employed on unskilled seasonal work for short periods but also large numbers whose chief occupation is farm work but who find employment in other occupations, such as roadmending, in the winter when the demand for labour on the farm is at its lowest.

Work on the farm is necessarily dependent on the time of year and the weather. It was formerly the practice to suspend men (to "stand them off" as the phrase ran) in wet weather. As labour became more mobile and migration from the villages became common, employment on farms tended to be more stable and every farmer aimed at keeping a permanent staff all the year round, engaging casual workers only in times of greatest pressure. The practice of "standing off" in wet weather was gradually discontinued, and, in effect, finally abolished by the Agricultural Wages Board established in 1917.

The "gang" system of organizing casual and seasonal labour was general in the last century but it gradually fell into disrepute. Under this system a number of men and women were collected by a gangmaster and travelled from farm to farm for seasonal operations. The gangmaster made a contract with the farmer to do certain work for a specified amount and divided the payment among the members of the gang. The system obviously lent itself to abuse by unscrupulous gangmasters while the association of men and women for considerable periods without fixed abodes and often without decent accommodation either by day or night led to scandal and disorder.

Classes.—The popular belief that the work of the agricultural labourer is "unskilled" is not justified by the facts. Adam Smith compared agricultural and industrial labour thus: "Many inferior

branches of country labour require much more skill and experience than the greater part of mechanic trades. The man who works upon brass and iron works with instruments and materials of which the temper is always the same, or very nearly the same. But the man who ploughs the ground with a team of horses or oxen works with instruments of which the health, strength and temper are very different on different occasions. The condition of the material which he works upon too is as variable as that of the instruments he works with, and both require to be managed with much judgment and discretion." The introduction also of numerous machines and implements in farm work calls for greater versatility and resourcefulness on the part of the farm worker to-day.

Those who are regarded as specially skilled in farm work, and are usually paid a higher wage than the ordinary labourer, are those who have charge of stock. Their additional remuneration is partly in respect of longer hours but it is also paid in consideration of their knowledge and experience and of the responsibility placed on them. Shepherds are generally the most highly paid men on a farm, and where the flocks are large the responsibility placed on them is great. During the lambing season they not only have to be in constant attendance day and night but they must possess some elementary knowledge of veterinary science. It is a common practice to give shepherds a bonus, in addition to their wages, on the number of lambs successfully reared by them.

Men who have charge of cattle are termed in various districts cattlemen, stockmen or cowmen. In Norfolk there are also classes known as bullock-tenders and sheep-tenders who receive generally the same rate of wages as cowmen. Men who have charge of horses are termed carters, waggoners, horsemen or teamsmen.

On the larger farms there is usually a foreman (termed in Scotland a grieve) who is responsible for the general oversight of the men and the organisation of labour. His position and emoluments vary according to the size of the farm, the number of men under him and the extent to which the employer himself takes an active part in the management of the farm.

Organization.—The combination of workers for the advancement of their economic interests and particularly for collective bargaining with their employers has taken comparatively little permanent hold of agricultural labourers in any country. In England, apart from a few spasmodic local efforts, the first organized attempt to establish an agricultural trade union was made in 1872 under the leadership of Joseph Arch. A National Agricultural Labourers' Union was formed which in a short time enrolled about 70,000 members. In the face of strenuous and organized opposition from farmers it soon collapsed and no serious attempt to revive it was made until the beginning of the present century. In 1911 the National Agricultural Labourers' and Rural Workers' Union was started and by the end of 1913 had a membership of nearly 12,000. The establishment of the Agricultural Wages Board and its district committees, in which organization agricultural labourers were given by act of parliament equal rights and representation with farmers, gave an impetus to the organization of farm-workers. In 1919 it was reckoned that about half the agricultural labourers were enrolled, but after 1921 the membership again rapidly diminished and in 1926 not more than about 6 per cent. retained their membership.

Agricultural labourers are not included in the Unemployment Insurance act. In 1926 a departmental committee recommended, by a majority of one, the establishment of a special system of unemployment insurance for agricultural labourers in England and Wales, but the recommendation was not adopted by the Government. (R. H. R.)

United States.—Over the United States as a whole there is less than one hired agricultural labourer per farm. The total number of farms is approximately $6\frac{1}{4}$ million, while the number of farm-labourers varies from about 3 million in January to at least 4 million in the cropping seasons. The January figure represents mainly the permanently employed—the class that makes agricultural labour its steady occupation.

The relatively small number of farm-labourers is due to the fact that the typical American farm is a family enterprise. Ord-

inarily the family is large. In some regions there is also considerable exchange of work among farmers on adjacent farms. The number of hired labourers is steadily though slowly diminishing, as the increasing knowledge of agricultural science and the perfection of agricultural machinery cause the production per man constantly to grow. At certain times of the year much casual labour is employed on farms, as for fruit picking and wheat harvesting. The extra labour employed in the latter amounts to approximately 100,000 men per season. In a country the size of the United States the wheat in various regions ripens at different times, and the labourers follow the harvest from place to place. They constitute a heterogeneous group, ranging from university students earning money in their vacations to unskilled, sometimes illiterate, labour from cities.

The extent to which labour is employed throughout the year varies with the region and the type of farming practised. Dairying and live stock husbandry, coupled with diversified cropping, make for a fairly uniform employment of labour at all seasons. On the other hand, the vast wheat farms of the Great Plains offer principally a seasonal demand for labour. Some of these farms are wholly uninhabited by human beings during most of the year. New England and New York have had for generations a tradition in favour of permanent employment of farm-labour, with a strong preference for keeping the same persons year after year. The tendency has been for the farmer to assume a patriarchal attitude toward his help. The unmarried farm-labourer used to occupy a real place in all the life of the farm family. In early days the comparatively high wages and low prices for land—when an acre could be purchased with a single day's labour—attracted a fairly high type of labour to the farms. With the increased price of land, the growth of opportunities in the cities, and increasing dislike of labourers for absolutism in their employers, the type of farm-labour has doubtless declined. There is also a tendency to depart from the custom of making the hired man practically a member of the family, although the old practice still prevails to a large extent, especially in the East.

The average prevailing farm wage rate for the United States on Jan. 1, 1928, was \$32.50 a month with board, and \$46.75 a month without board. The highest wage rates—about 50% above these figures—are found in the Western States, and the lowest—about 25% beneath these figures—in the South Central States. The wages of casual labour at rush seasons, of course, are much higher. A large proportion of farm-labourers are single men. These almost invariably receive board. Married men usually are supplied with a house or cabin and with some such perquisites as fuel, some food, use of horses and farm tools and garden space. Not infrequently a man and his wife are both employed on the farm—he at farm work, she in domestic matters. Hours of labour on the farm average considerably longer per day, at least throughout the cropping seasons, than in industrial life, although, except in harvest and similar rush times, there is freedom from the pressure characteristic of factory work.

American farm-labour is largely unorganized. The Industrial Workers of the World at one time had a considerable membership of casual farm as well as other labour, but the number is apparently diminishing. The Sheep Shearers' Union of North America, with headquarters at Butte, Mont., has branches in several States. It has no connection with any other union. A few scattered local organizations of farm-labourers have sprung up from time to time, but have developed only to a slight extent. Operating farmers generally are hostile to unions. (N. A. C.)

AGRICULTURAL MACHINERY AND IMPLEMENTS. At the dawn of history we find man practising the most elementary method of modifying soil conditions. He broke up the surface and prepared a seed bed, using for this purpose the most primitive of all cultivating devices, a digging implement in nature like a hoe. The seed was sown by hand and the husbandman either drove his domesticated animals over the land to cover the seed and consolidate the ground, or used a form of harrow or similar implement or a bundle of twigs for the purpose. In early times the principal crops were cereals or pulse and a fibre crop—flax. Harvesting was performed by means of a sickle, an early

example of which, found in the Fayum in Egypt, consists of a wooden rod fitted with flint blades; metal was employed later, and a bronze sickle of about 1000 B.C. is the counterpart of the modern sickle. The crops were carried to a threshing floor where the grain was trodden out by animals, crushed out by sledges or beaten out with flails. The corn was winnowed by casting it through the air with a spade or shovel and fanning or allowing the wind to separate the heavy grain from the lighter husks.

The greatest mechanical advance during these early days of agriculture was the evolution of the plough from the primitive hoe. This transition is very clearly seen in ancient Egypt. The advent of the plough enabled man to supplement his labour by animal power and is one of the great landmarks of agricultural progress. Mesopotamia furnishes evidence of the use of a primitive combined plough and drill, but it is doubtful whether the implement had any advantage over the customary methods; at all events it was lost to later civilization. By Roman times a primitive ridging plough had been evolved by the use of a device resembling the modern double mould board. When the single mould board was developed or when wheels were added to the plough is not definitely known. Pliny, the elder, who lived in the first century, mentions a wheel plough, but the use of such ploughs did not become general until much later. Pliny also reported the use in Gaul of a harvesting device, which was pushed by oxen, for heading or stripping the grain. But ancient civilizations did not make any considerable progress on the mechanical side of agriculture and such mechanical contrivances as were used disappeared with the barbarian invasions.

During the middle ages and until after the Renaissance the variety of implements at the disposal of the husbandman had advanced but little, though the roller was known but was not employed generally in agriculture. It must not, however, be supposed that there was absolute sameness or an uncritical acceptance of the implements handed down from previous generations. Fitzherbert's *Book of Husbandry*, printed in England in 1523, mentions the different types of plough used in different districts and attempts to give reasons for the differences in design. Fitzherbert appears to have realized that the design of the plough must be modified to reduce the draught in different kinds of soil. Hand tools had been perfected and often represent, even in small details, the hand tools in use to-day. By the year 1600 more elaborate implements were coming into use, and more than one book published in England about this time deals with the "new and admirable art of setting of corn." About 1730 Jethro Tull (*q.v.*), who is renowned for his horse-hoeing husbandry, developed a seed drill which was really workable, although its general adoption was hampered by Tull's advocacy of impracticable methods of cultivation.

In the eighteenth century there was a conscious and organized attempt to improve agricultural implements, and in England the Society of Arts, which had been founded in 1754, encouraged the movement by the offer of premiums. Ploughing matches were held in many parts of the country and attracted general support from farmers and their men. There were also competitions in the use of drills and horse-hoes. New methods and inventions were being applied to most farming operations, and new conditions were being created favourable for the great advance which followed.

The Steam Engine.—By the 19th century such a complexity had been introduced as to justify the use of the term "agricultural machinery." In agriculture, as in the manufacturing industry, the use first of water-power and then of steam had immensely stimulated the invention of machinery supplementing or replacing manual labour. A workable threshing machine was invented late in the 18th century and was gradually coming into use early in the 19th; it was driven by water or wind power, sometimes by horse labour, and later by steam. But it was not until the '30s of the 19th century that steam began to be applied at all extensively to agriculture. A system was then introduced whereby one or two engines were employed to draw multi-furrowed ploughs, by means of cables, backwards and forwards across the field, and after a good deal of experimentation the established system of steam-ploughing with a double-engined cable set was devised in the fif-

ties. Heavy implements such as the cultivator and mole plough were later added to the equipment of steam tackle; mechanical threshing became popular and steam-engines were also used to some extent to drive barn machinery. Nevertheless, for the most part the development of agricultural machinery upon the farm owes little directly to steam. The mowing machine and the self-binder, the tedder and swath-turner, the drill, the potato-digger, chaff-cutters and root-cutters, all have been developed in the first instance for horse or manual labour, though doubtless receiving a fresh stimulus from the general mechanization of industry applied to the farm and the still greater stimulus, in Britain as in America, arising from a shortage of cheap labour.

The Internal-combustion Engine.—In still more recent times an important practical contribution to the mechanization of the farm came from the discovery of the internal-combustion engine. Used first of all to drive stationary machinery, as chaff-cutters, root-cutters and corn-mills in the barn, in the second decade of the 20th century the internal-combustion engine also made headway as a source of power for field operations. Steam-engines, though widely used for traction on the road, suffered the disadvantage of being heavy for use on the land for the direct haulage of machinery and implements; it was not until the internal-combustion engine had been perfected that agricultural tractors made their appearance in any number.

This type of tractor has now an established position on the farm on both sides of the Atlantic; it supplies power for ploughing, cultivating and harvesting; it can both drive and haul the threshing-machine, and there can be no doubt it contains the promise of still further usefulness. The practice of mole-draining, for example, has been greatly stimulated not only in Britain but on the Continent of Europe by the invention of mole-ploughs that can be hauled by a suitable agricultural tractor. The cost of the work is substantially less than when performed by steam tackle and is far more expeditious than when performed by horses. The tractor has also rendered it easier for the farmer to undertake deep ploughing and subsoiling, which are very important for growing a crop such as sugar beet. Subsoiling had been looked on with disfavour because of the heavy strain imposed upon the teams and, when carried out at all, had been left in great measure to steam tackle. The application of the internal combustion engine has also enabled designers to produce machines of more moderate size and weight than formerly.

Another direction in which the internal-combustion engine is likely to prove its usefulness is in rotary tillage. This is a system which may ultimately replace ploughing and subsequent cultivating by a single operation. It has been advocated since the first half of the 19th century, and many attempts have been made to devise an effective machine, the best known being the Darby digger which inverted the soil by an action somewhat resembling that of the spade. The most promising machines make use of revolving tines for disintegrating the soil and the tines revolve in such a way as to assist the propulsion of the machine. The advantages and limitations of rotary tillage have still to be tried out. In a climate like that of Great Britain the combined effects of autumn or winter ploughing and frost may not be attainable by rotary tillage. Given suitable soil and climatic conditions, however, the potential advantages of preparing a seed-bed at one operation and on a considerable scale are obvious.

The internal-combustion engine thus enables operations to be efficiently performed which were beyond the resources of the ordinary farmer, or which were little more than ideas in the days of steam and horse labour. But this is not its only or perhaps its chief usefulness. It enables operations to be performed far more speedily with an equal labour force and is therefore an ally to the farmer in his struggle against adverse weather conditions. Obviously, if five or six acres can be ploughed in a day by a tractor where formerly a plough-team accounted for less than one acre, another factor than the unit cost of the ploughing, namely, that of speed or of the time conditions, has entered into the operations. Again, if 20 acres can be reaped in a day as against ten or 12 acres by two teams of horses, the same factor enters. Full advantage, however, cannot be taken of the tractor when the implements

and machines used with it are those designed and constructed for horse haulage; to obtain the full benefit implements expressly designed for tractor work must be employed.

In the cable system of ploughing and cultivating, the internal-combustion engine appears likely also to replace steam. The ease of handling oil fuel as compared with the difficulties often attending the transport of water and coal or wood must, it would seem, in the long run prove the decisive factor. The advent of the producer-gas plant for use with tractors and lorries is also likely to extend the use of the internal-combustion engine in countries where liquid fuel is scarce and suitable materials for producing gas are available. The possibilities of the production of power alcohol on a commercial scale must also be borne in mind when considering the future sources of energy for the farmer.

Electricity.—But a still newer source of power which has made its appearance upon the farm is electricity. Owing to the shortage of coal and oil fuel during the War period, a stimulus was given to the exploitation of water-power and electricity undertakings. Although employed at first principally for lighting, electricity, when it is available at low cost relatively to other forms of power, is gradually coming into use for driving stationary machinery on the farm. Its further use for cultivating the land has scarcely gone beyond the experimental stage as yet, although systems of cable ploughing in which electric motors are employed are actually in operation in several European countries. The principal difficulty is the transmission of current to every part of the farm where it may be needed, since equipment with transmission lines may involve serious expense.

Other Mechanical Progress.—The gradual mechanisation of the farm is apparent, however, not only in those branches of agriculture and methods of operations which are of long standing. As new crops are introduced or old crops revived, mechanical means are devised to deal with them. Each crop indeed demands its appropriate machines. A crop such as sugar beet, when introduced into a country where labour is dear, requires effective mechanical means for dealing with it at all its stages, but particularly for har-

COURTESY OF J. I. CASE THRESHING MACHINE COMPANY

A DISC-HARROW DRIVEN BY A GENERAL UTILITY TRACTOR TO WHICH A PLOUGH OR A SMALL GRAIN SEEDING DEVICE CAN ALSO BE HITCHED

vesting—the most arduous of the whole cycle of operations; consequently it is necessary to devise mechanical lifters and toppers as substitutes for the hand labour employed in countries where wages are low. Similarly with the flax crop; its revival in Britain has led to concentration on the problems of harvesting and the preparation of the fibre for the spinner. Machines for pulling the crop and for scutching (or dressing) the straw have been devised, and new mechanical processes have been advocated to supersede entirely the traditional hand methods.

Classification of Machinery.—Agricultural implements and machines are now very numerous and very diversified and may be considered under five main groups, namely: (1) *prime-movers*, i.e., engines of all kinds, tractors, water-wheels, windmills, etc.; (2) *cultivating machinery*, including ploughs of all kinds, rotary tillers,

harrows, hoes, scarifiers, rollers, manure distributors, drills, mole-ploughs, etc.; (3) *harvesting machinery*, including mowers, rakes, swath-turners, tedders, reapers, self-binders, threshing machines, elevators, potato lifters, beet toppers and lifters, crop drying plants, etc.; (4) *stationary or barn machinery*, including such food-preparing machines as cake-breakers, chaff cutters, grinding and crushing mills, root-cutters, etc.; (5) *dairy machinery*, including milking machines, separators, churns, butter workers, sterilizing and bottling machines, etc. In addition, there are a number of miscellaneous machines, including sprayers, sheep-shearing and horse-clipping machines.

Economics of Machinery.—From the development of such mechanical devices it does not, however, follow that every farmer can economically use machinery for all possible purposes. With his small acreage of grass and cereals the small-holder, for example, would probably not feel justified in purchasing any harvesting machinery, except a horse rake and a combined mower and reaper, whilst the farmer with a holding of 300 acres or so of mixed arable and pasture land would find it necessary to have a complete outfit of cultivating, harvesting and stationary machinery, besides many dairy appliances if milk production were also an important part of his enterprise. In suitable circumstances he would probably also find it desirable to supplement horse labour by one or more tractors and would probably thresh his own produce. But on very large arable farms, such as extend in some parts of the world to several thousands of acres, the range of agricultural machinery would include cable sets and possibly even trenching machines for excavating and grading drains and ditches.

The economic use of machinery in agriculture is dependent on a number of factors which vary from country to country, from district to district, and from one type and size of farm to another, but there is one principle common to all cases: a machine must do sufficient work to repay its capital outlay and working costs over a reasonable period. To meet this requirement the minimum amount of work must be available before any particular machine can be employed economically. The potato crop furnishes an excellent illustration. The cheapest way to lift a small plot of potatoes is by hand forking; the lifting of an area of an acre or so will repay the cost of a simple potato plough; while a larger area will justify the purchase of a potato-lifting machine. But the use of machinery depends also on other factors besides cheapness in comparison with other methods. Speed of work and ability to take advantage of favourable weather are factors which may influence considerably the adoption of mechanical devices, although it may be difficult for any system of farm costings to take cognisance of these advantages. Emphasis must at present be laid on the paucity of accurate knowledge regarding the cost of farming operations in general, though efforts have in recent years been made in Europe and America to analyse farm costs and to stimulate the adoption by farmers of some simplified system of cost accounting. The comparative cost of individual operations or units of work is, however, not sufficient; the problem from the farmer's point of view is rather the production of food units at a minimum cost, and the marketing of them either directly or by feeding to stock in such a way as to obtain a maximum return on the capital outlay involved.

Social Effects of Machinery.—It is sometimes supposed that the introduction of machinery has led to rural depopulation and will intensify it. But even in older countries machinery has more often than not been introduced because a labour supply of a particular kind has failed; for example, the falling-off of casual and migrant labour at harvest time due to a number of social causes has encouraged the widespread adoption of the self-binder. In newer countries the introduction of machinery has had the effect of populating waste areas, for the vast tracts of new land in the United States, Australia, Canada, etc., could not be farmed in present circumstances without the aid of machinery; the alternative would be timber production or stock raising.

The use of machinery also requires skilled workers, and the more widespread the use of machinery becomes in agriculture the more highly skilled will be the farmworkers. The mechanisation of agriculture also means that a higher wage can be paid because the unit

of production is enlarged, but as a corollary it also indicates larger farms or groups of small farms worked as one economic unit. The alternative is a system of peasant holdings with primitive methods; but the Western world is steadily moving away from the social conditions which made such a system possible.

UNITED STATES

As industry has developed and has built great cities, it has called man-labour from the country. This labour has been replaced by agricultural machinery and implements. The extent to which this has happened in the United States is indicated in fig. 1. Although the total population of the United States in 1927 was a little more than five times as great as in 1850, and although the acreage of improved farm land increased about $4\frac{1}{2}$ times during the same period, yet the number of agricultural workers in 1927 was a little less than three times the number in 1850. Seventy-five years ago the proportion of total population to agricultural workers was slightly over six to one. Better adaptation of crops to soils and climate, and increased yields per acre, are probably the main reasons why the acreage of improved farm land has not kept pace with the increase in total population. But had it not been for the introduction of machinery which increased the effectiveness of man-labour on the farm, an increasing number of acres to feed and help clothe a rapidly increasing population must have been accompanied by a much more nearly equal increase in agricultural workers.

Effect on Time, Man-labour and Production.—Since 1850, when the application of machinery to farming began in earnest, the average acres of improved land per agricultural worker in the United States increased steadily from 30.4 acres to 47.2 acres in 1920; and the value of agricultural implements and machinery per agricultural worker increased from \$40.77 in 1850 to over \$200 in 1925. The 13th annual report of the United States Department of Labor shows that the man-labour requirement to produce twenty bushels (one acre) of wheat by the hand methods of 1830 was 61 hours and 5 minutes, at a labour cost of \$4.00; by the machine methods of 1895, only 3 hours and 19 minutes, at a labour cost of \$1.12 were necessary to produce the same amount. By the hand methods of 1855 an acre of corn required nearly 39 hours of man-labour; in 1894 it required slightly over 15 hours with machinery. Using the estimates of the Department of Labor for nine important crops (barley, corn, cotton, hay, oats, potatoes, rice, rye, wheat) and comparing the machine methods of about 1895 with the hand methods of earlier times, H. W. Quaintance (*The Influence of Farm Machinery on Production and La-*

FIG. 1.—GRAPH SHOWING VARIATION IN POPULATION, IN AGRICULTURAL WORKERS AND IN ACREAGE OF IMPROVED FARM LANDS IN THE UNITED STATES

bour) states: "Taking the per cent of labour saved as indicating the average proportion of these crops due to the use of machinery, it appears that the quantity of products is almost five times as great, per unit of labour, as it formerly was." This suggests how machinery has freed labour from agriculture for service in industry and commerce. After an extensive study and presentation of data on 15 crops (barley, broom corn, corn, cotton, hay, oats, onions, peas, potatoes, rice, rye, sugar cane, sweet potatoes, tobacco, wheat) grown in the United States, the same author says: "Surely it will not be too much to say that during the last half of the 19th century the cost of production¹ of these crops was reduced by one half." That the influence of machinery on labour has continued since 1895 is evidenced by the fact that now it is not uncommon to hear of farmers in the United States and Canada who, by the most modern machine methods, produce wheat and corn with a man-labour requirement per acre of only two and six hours respectively.

Influence on Quality of Work and of Product.—As inferred previously, increased yields per acre, and improved quality of product, are due to a number of factors; but the importance of one of these is not to be overlooked here. The improved methods in farming made practicable by machinery have a marked influence on the quality of work done by the farmer, and on the quantity and quality of the product. By the use of better designed, better adapted and more effective soil working, grain grading, seeding and harvesting machinery, sounder seed is more evenly sown in a better seed bed; a larger yield is promised and a more uniform and cleaner product is marketed. Modern spraying equipment not only saves the fruit crop, but its use also means better quality; then modern sorting and packing machines grade the product to command the best market price. These are but a few of scores of illustrations; yet, that is not all. Up-to-date machinery in agriculture permits better utilization of products; for instance, the feed grinder, silage cutter and shredder have increased the feeding value of roughage, and the manure spreader permits better utilization of animal refuse to help maintain fertility and good tilth.

Other Effects.—Although the average acreage of improved land per farm in the United States has fluctuated somewhat since 1850, economists point out that in the north central states, in which machinery has been more widely applied to general farming than in other divisions, the improved land acreage per farm has steadily increased; likewise, the average number of crop acres per farm in these states has increased during the period for which data are available. In other sections of the country where general farming has been practised and where machinery has not been so widely adapted, not only are the tendencies just mentioned less apparent but, even at times, there is a marked tendency toward smaller farms. In Canada, the average acreage of improved land per farm has increased steadily from 59 acres in 1901 to 99 acres in 1912; during the same period agricultural implements and machinery increased approximately from six to ten per cent of the total value of all farm property. If the total investment in all farm property in the United States is considered, the increase since 1850 has been much greater in the agricultural divisions of the country in which machinery is widely used. The greatest item in the value of farm property is the value of the land itself; and land values are based somewhat upon earning capacity. Of course, the increase in value of all farm property may be due to several factors; but, the ability of machinery to cut down the cost of production and thereby increase net profit is not to be overlooked as having had and continuing to have an influence on land value.

By lessening the time necessary to perform farm work, machinery has assisted in shortening the working day. Also, it has changed the character of the work in a way that has important social bearing. In 1880 it was easier physically and more pleasant

¹Cost of production here is based on cost of labour and does not include differences in machine overhead between hand and machine methods. This discrepancy, if it seems such, is more than offset by the fact that labour by hand methods is figured at the rate of about 1850, while for machine methods it is computed on the basis of the higher wages current about 1895.

mentally to thresh grain with a threshing machine than to use the flail of 1820. Likewise, it is easier to-day to sit upon a combination harvester-thresher, guide the machine and control the power than it was to pitch bundles and straw in the days of 1880. In this sense, agricultural machinery is truly "labour saving" in that it has relieved farm work of much of the old, arduous, physical exertion so often characterized as drudgery, and demanded in its place greater skill and more intelligence on the part of the operator. The modern farmer whose business demands extensive use of agricultural machinery is just as busy, if not

BY COURTESY OF H. A. STROHMMEYER, JR.

MODERN THRESHING. A SPEEDIER AND EASIER OPERATION THAN IT WAS 50 YEARS AGO BEFORE ENGINE-DRIVEN MACHINES WERE KNOWN

busier, than his grandfather, but his work is more mental and less manual. Modern farming is a complex business requiring study, wise planning and careful execution. To be sure, the farmer of to-day works hard physically as well as mentally, but, by lessening the time requirement for various farm operations and by eliminating much of the old drudgery, farm machinery and household conveniences allow the farmer and his wife and children more time for reading, for thinking, for recreation and for self-improvement.

Classification.—Types, kinds and sizes of agricultural machinery and implements form a complex subject. Agricultural conditions into which machinery must fit vary widely between the one-mule farms of the cotton-belt and the great wheat ranches of Canada; the operation of a New England farm varies from that of a corn-belt farm, and the latter, in turn, is vastly different from the California fruit ranch. Differences in sizes of farms, in size of fields, in kinds of crops grown, and in the kind and size of power units most economical or practical—all cause variation in type and size of machine or implement. For a small field, one can buy a one-horse implement for a very few dollars, or, for a great plantation one may buy a special harvester which costs several thousand dollars. Because of the wide variation in soil types, the large manufacturer selling nationally finds it necessary to make over one hundred different shapes and kinds of mouldboards for ploughs in addition to the disc type of plough which is demanded in very hard, in very fluffy or in very sticky soils. Land values have some influence. Then, last but not least, the human equation enters; differences in peoples and in regional customs add complication. The farm labourer of low mental calibre and of little mechanical skill requires a smaller, simpler implement than the skilled operator who commands a 60-horsepower tractor hauling a combination of implements which performs two or three operations in one trip over the ground.

Space does not permit description of all kinds of agricultural machines and implements. Fortunately, however, the subject lends itself to classification according to the purpose of the machine. Most of the agricultural machines, implements and tools used by farmers in the United States and Canada may be classified according to purpose. The list includes only those items considered part of the business of raising or making agricultural products up to the moment those products are sold. It does not include the strictly household conveniences, devices and utilities which are becoming so widely adapted to assist the housewife

and to enable the farmer and his family to enjoy more the art of living.

Machines and Implements for the Reclamation, Maintenance or Improvement of Land: stump pullers, pilers; brush breakers, cutters, burners; open ditch, tile ditch and mole ditch machines; land drain cleaners; land levellers; terracing scrapers, graders; irrigation pumps, sprinklers, water controls, ditchers; sub-soilers; limestone crushers; lime and fertilizer distributors; manure loaders, spreaders; straw spreaders.

Machines and Implements for Seed-Bed Preparation: mouldboard and disc ploughs; drags; spike-tooth, spring-tooth, disc and special harrows; smoothers and pulverizers; plain, corrugated and bar rollers; surface and subsurface packers; clod crushers; special tillers; sweeps; listers; ridge busters; stalk cutters, shavers; cotton stalk choppers; stubble diggers, pulverizers; markers.

Machines and Implements for Seed Preparation: fanning mills; grain, pea, bean, cotton seed, peanut, flax, onion set, rice, potato and corn cleaners, graders and sorters; seed scarifiers; seed testers; seed stringers; seed driers; butters and tippers; potato cutters.

Machines and Implements for Seeding and Planting: broadcasters; grain, beet, grass and garden seed, bean, pea, corn, onion and rice drills; corn, cotton, beet, potato, pea, bean, onion and peanut planters; transplanters; seeders; markers; lister-planters; fertilizing attachments.

Machines and Implements for Cultivating: corn, beet, cotton, potato, sugar cane, vineyard, orchard and garden cultivators; celery; potato and tobacco hillers; drags; spike-tooth, spring-tooth and disc harrows; weeder; rotary hoes; ridgers; renovators; sweeps; root blockers; cotton scrapers, choppers; thinners.

Machines and Implements for Harvesting: mowers; tedders; "flop-over," dump and side delivery rakes; "bull" and sweep rakes; hay, shock, bundle and cane loaders; stackers; bunchers; windrowers; reapers; grain and corn binders; grain and corn headers; header-binders; combination harvester-threshers; corn, cotton, potato, peanut and fruit pickers; root and plant lifters; potato and peanut diggers; root toppers; bean, pea, beet, celery, grass seed and onion harvesters; field ensilage harvesters; seed and cotton strippers; sugar cane cutters, harvesters; corn and hemp cutters; grain and corn shockers; shock compressors, movers, sweeps; huskers; milking machines; wool clippers; tree fellers.

Machines for Preparing Products for Market: grain, pea, bean, peanut and rice threshers and cleaners; alfalfa, clover, almond, bean, pea, grain and rice hullers; grain, pea, bean, cotton seed, peanut, onion set, rice, potato, corn, berry and fruit cleaners, graders and sorters; cotton gins and presses; balers; produce washers; grain polishers; corn, peanut, rice and pop-corn shellers; vegetable bunchers; cream separators; milk emulsifiers, pasteurizers, sterilizers, coolers, aerators; churns; butter workers; bottling machines; cheese and lard presses; sugar, fruit, sorghum and syrup evaporators; honey extractors; berry and fruit crushers; cider and juice mills, presses,

A POWER DRIVEN SPRING-TOOTH HARROW, OPERATED BY ONE MAN AND EMPLOYED IN PREPARING AND CULTIVATING THE SEED BED

extractors; bleachers; pitters; parers; sugar cane and sorghum mills; hemp breakers and cleaners; saw mills; baggers; weighers.

Machines for Feed Preparation and Feeding: cutting boxes; ensilage and fodder cutters; feed mills, grinders, mealers; roughage mealers; feed mixers; shredders; root and vegetable cutters, pulpers; feed cookers; stock feeders; bone cutters; corn and cob crushers; silo packers.

Machines and Implements for Combating Crop Enemies: sprayers; dusters; field burners; stubble pulverizers; insect sweeps, catchers, traps; tobacco bed burners; seed treaters; smut cleaners; fumigators.

Machines, Implements and Conveyances for Transportation: automobiles; motor trucks; wagons; carriages; horse and hand carts; sleighs; bobs; stone boats; wheelbarrows; farm, wagon, log, lumber, header and sugar-cane gears; racks and barge boxes; hay carriers,

forks, slings; blowers; grain dumps, elevators; car loaders; feed and litter carriers.

Power, Light and Heat Generators: gas, petrol, paraffin, distillate, hot air and steam engines; steam and internal combustion tractors; boilers; windmills; turbines; water wheels; hydraulic rams; tread mills; power sweeps; electric motors, dynamos, generators; lighting plants; tank heaters.

Miscellaneous Machines, Implements and Tools: incubators and brooders; disc and knife grinders; pumps and pump jacks; hay

BEFORE THE ADVENT OF THE TRACTOR THE HORSE-DRAWN SPIKE-TOOTHED HARROW AS ABOVE WAS AN IMPLEMENT IN COMMON USE

knives and hooks; hand hoes, rakes, shovels, forks; corn, cane, tobacco and cabbage knives; pruning and grafting hooks, knives, shears and saws; fence stretchers; hog rubs; post hole augers; lifting jacks; animal pokes and leads; dehorner; horse and cattle clippers; grooming machines; milk and cream testers; utensil washers, sterilizers; scales; ladders; hand tools and machines for wood and iron work.

Historical Sketch.—Attempting to determine whether changes in agriculture were the cause or the result of the introduction and improvement of machinery is like trying to decide which came first—the hen or the egg. Undoubtedly, a change in agriculture at times caused sharp changes in agricultural machinery; at other times, advancement in agricultural machinery permitted, if not actually caused, marked changes in agriculture. The two are so interdependent that a historical sketch should review the status of machinery and implements in each of the five great periods in the history of American agriculture, as well as point out the high spots in the history of machinery itself.

During the colonial period (1607 to 1783), farming was on a self-sufficing basis; that is, the farmer made his own shelter, he and his family made much of what they wore, and, with the exception of some wheat, tobacco, rice and indigo, the farmer raised but little more than was required for his own family. The ground was spaded or hoed up, or it was ploughed with a crude, "bull" plough which carried a wooden mouldboard sometimes stripped with iron. Farmers who were fortunate enough to own these home-made ploughs often ploughed for others. If the seedbed was harrowed at all, a "peg tooth" harrow was used; this was a wooden frame with wooden spikes for teeth. Small grain was sown broadcast by hand; sometimes it was harrowed in or was trodden in by animals. The new crop was cut with a hand sickle, scythe or cradle, threshed with hand flail or by driving animals over it on a treading floor; then the grain was winnowed by casting it against a light wind. Corn was dropped, covered, cultivated and harvested entirely by hand. Wooden-wheeled carts were used; but evidently these were not as popular as one would suppose, because there is evidence that tobacco was placed in huge barrels which were rolled to the market point. Thus, with the exception of a great number of hand tools, crude forms of the plough, harrow and wagon were the only agricultural implements of the colonial period.

With only one or two notable exceptions the same conditions held and the same old implements were used throughout the second period (1783-1830) of agricultural history. This period was characterized by the beginnings of the public land policy and of expansion westward, and by the increasing importance of cotton in the South. Early in the 1790's the Ely cotton gin appeared; this made the removal of the seed from the cotton mechanically

possible and was a great boon to the young cotton industry. The influence of the cotton gin has been so far-reaching economically, commercially and socially that it is considered one of the high lights in the history of agricultural machinery.

About 1797 Newbold demonstrated his cast-iron plough. It was similar to the cast-iron ploughs which had been demonstrated shortly before in England. Records indicate that farmers feared detrimental effects from so much iron in contact with the soil, and evidently this first American cast plough was never repaired after its mouldboard became broken. Hence wooden ploughs, some of which carried wrought-iron cutting edges, continued well throughout the period. Between 1814 and 1820, however, Wood, evidently continuing the meditations of Thomas Jefferson on the mathematics and mechanics of the mouldboard, began to give the plough bottom scientific shape for better turning, pulverizing and for lighter draft. To secure these shapes Wood had to cast his ploughs, and he introduced the important feature of having parts of the plough renewable.

During the latter part of this period a cutting box to cut up roughage for feed, a cultivator for row crops, a horse rake and the Bailey mower appeared. The mower cut by means of a large circular blade which revolved against the grass evidently to imitate the cutting action of the old scythe blade. The cutting box, cultivator and rake ideas were perpetuated, but this device for mowing was not further developed. It is claimed that a few "chaff piler" or "ground hog" threshers were used as early as 1825; these rubbed the grain from the heads but did not separate it from the chaff or straw. These implements, although their use did not become general until later, are mentioned here to show that, as farming moved westward and larger or new tracts of land became available to the farmer, there began a real attempt to furnish machinery to supplant a growing shortage of labour.

At no time has American agriculture undergone such changes as during its third historical period (1830-1860), and at no time has agricultural machinery been so involved in a transitory period. At the beginning of this period the farmer produced first for himself and family; at the close he was raising crops chiefly to sell. As the new railroads opened up the interior, agricultural products were shipped into the East to be laid down on the

BY COURTESY OF THE J. I. CASE THRESHING MACHINE COMPANY

A LISTER WHICH THROWS UP A SLOPING RIDGE AND CUTS OFF THE SQUARE SHOULDER

seaboard in such quantities as to affect almost the entire world. The repeal of the Corn Laws in England, the rapid development of manufacturing both in England and America, the potato famine in Ireland and the settling of western lands by thousands of immigrants following the German revolution of 1848 all gave stimulus to American agriculture. Not only did breaking and cultivating the black lands of the Middle West present new problems in soil working implements, but also over the entire country farmers awoke to the pressing need of a cheaper, faster way of doing things. This led to an outstanding period of invention and to the real beginning of implement factories to supplant the country blacksmiths who for years had been supplying local patrons with crude implements fashioned largely after their own individual ideas.

The obstinate scouring qualities of the soils in the Mississippi valley led to the use of steel instead of iron strips to face the mouldboards of ploughs. In 1833 John Lane built the first steel mouldboard, using cross-cut saws for the purpose. John Deere starting in 1837, and William Parlin beginning in 1842, were other pioneers in the steel plough business of the Middle West. Much credit is due also to James Oliver who, beginning his experiments in 1853, greatly advanced the process of chilling cast plough parts, thus securing greater durability and improving the scouring qualities of this type of plough.

Early in the '30s the Manning, the Hussey and McCormick

patents brought out the idea of cutting grass and grain by a reciprocating knife passing through fingers or guards. It is this principle upon which modern mowers, binders, headers and combination harvester-threshers still operate.

Other patents and developments of note during the early part of this period related to corn shellers, fanning mills, grain drills, and to tread-powers and power-sweeps, whereby the power of horses or oxen could be utilized to drive the rotating parts of such stationary machines as threshers. In 1834 Pitts combined a "ground-hog" thresher and a fanning mill and thus started the development of the modern grain separator which threshes, cleans, weighs and bags the grain. Although they did not become popular until years afterward, nevertheless grain strippers and headers were patented during the twenty years prior to 1850.

By 1850 several factories had been established for the manufacture and sale of what were then improved and successful ploughs, harrows, grain drills, reapers, mowers, threshers, strippers and power-sweeps. Of course much work on the farm still had to be done by hand, and much improvement and many new devices were to appear after that date. But by that time the farming public was accepting mechanical devices so rapidly that 1850 is recorded by historians as the close of the period of "hand production" and the beginning of the machine era in American agriculture. The advent of machinery and implements placed farming on a commercial or production basis on which the farmer raised products to sell rather than simply to sustain himself and family. It is interesting to note that from 1850 to 1860 the number of establishments manufacturing agricultural machinery increased from 1,333 to 2,116.

From 1850 to 1860 patents appeared and development work was carried on on each of the following: force-feed devices in grain drills, stalk cutters, baling presses, two row corn planters, disc harrows, feed grinders and "straddle row" cultivators. Improvements continued on all classes of implements, especially on mowers, threshers and reapers. One of the most interesting developments concerned mechanical binding attachments made for and used to some extent on reapers. Most of these attachments used wire instead of twine; wire was costly and objectionable in the straw, and one step—that of elevating the grain and getting it automatically into good binding position—was lacking. At the time that the wire binding attachments were being developed, the Marsh brothers, about 1856, conceived the idea that two men, standing on a special platform at one side of the reaper, could bind the grain by hand providing it was elevated from the platform of the reaper and delivered to them on a binding table which they faced. Although the Marsh harvester of 1858 was originally designed to facilitate hand binding, nevertheless it is very important historically because it so materially solved the problem of grain delivery. It supplied the step just referred to as lacking with the early wire binding attachments, and became the foundation for the later binding machines which were simply to substitute automatic binding and tying devices for the two men that stood on the first Marsh harvester.

The fourth period in the history of American agriculture extends from 1860 to 1887. It was characterized by remarkable expansion, a chief cause of which was the passage of the Homestead Acts. The disbanding of the armies of the Civil War sent men and mules back to the land, and, machinery being available, many sought the agricultural opportunities of the far west which was about to be opened up by the completion of the trans-continental railroads. The perfection of the twine binder and the introduction of the roller process for flour manufacture also stimulated agricultural expansion.

The drain of the Civil War on farm labour forced farmers to the use of more and more machinery. During the war mowers came into very general use, and early in the period there was much done to perfect horse rakes which, as an accompaniment to the mower, could displace more labour in the haying process. This was to be followed soon, in 1872, by the development of hay forks, slings and carriers by which hay could be moved from the wagon to the mow or to the stack by horse power rather than by hand. Thus the production of hay had become mechanical

save for one step—that of loading. This gap began to be closed in 1874 when the mechanical hay loader appeared; the implement was considerably improved about 1880 and came into use about 1885. Although they had been patented years previously, two-wheeled sulky and gang ploughs did not appear in good quantities until about 1870. In 1868 John Lane, Jr., patented soft-centre steel for plough bottoms. About the same time disc harrow manufacture began in earnest.

The first automatic grain binder—that is, the first harvester of the Marsh type to carry an automatic bundle forming, compressing and tying attachment—appeared in 1870, and was known as the Locke machine. At last the tedious process of binding

BY COURTESY OF THE INTERNATIONAL HARVESTER COMPANY
THE MCCORMICK TWINE BINDER OF 1881. ONE OF THE FIRST HARVESTING MACHINES FOR THE AUTOMATIC BINDING OF WHEAT

sheaves by hand was doomed, and the importance of this development in history of agriculture can hardly be overestimated. Attachments using twine as the binding material, and some using wire, followed quickly. About 1878 the famous tying device known as the Appleby knotter appeared. It has become the standard tying mechanism of nearly all modern grain, rice and corn binders. Thus, the grain binder was the result of 40 years of struggle in which some men lost fortunes while others became prosperous. The grain binder is the product of no one man; it is the culmination of many ideas, only the fittest of which could survive.

Although combination harvesters and threshers had been thought of as early as 1826, it was not until about 1875 that the "combine" came into use, and then it appeared in the vast wheat fields of the Pacific coast states. These were large machines, drawn by from 12 to 30 horses, cutting a swath of grain from 16 to 24 ft. wide, and threshing, cleaning and sacking the grain in one trip over the field.

In 1875, largely through the activities of the Haworth brothers, automatic check-rowers for planting corn became practical. The dropping mechanism in these machines was operated by regularly spaced buttons on a wire stretched across the field, instead of by an extra man on the planter. Thus one man, and the previous operation of marking off the field, were eliminated from the planting process. In 1876 manure spreaders of the wagon type were developed to the practical stage. About the same time ensilage cutters, or silo fillers, and disc ploughs appeared, the latter, however, did not become commercially practicable until about 1890. Although stationary steam engines, and steam engines on trucks which could be hauled from place to place, had been used previously, the self-propelled steam traction engine did not appear in agriculture until about 1880. This was the forerunner of the modern tractor. In 1884 three-wheeled sulky and gang ploughs were developed; these were of high-lift design and the prototype of the modern riding plough used so extensively in both the United States and Canada. About 1885 a combination machine for husking corn and shredding the stalk made its appearance.

The fifth period in American agriculture, 1887 to the present time, began with the practical exhaustion of those public lands in the United States which could be converted easily and cheaply into quick producing farms. Since 1887 agriculture has been settling down to more intensive cultivation accompanied by improvement in farms and the subsequent rise in land values. (The same tendency is in evidence in Canada, though there the cor-

IMPROVED FARM MACHINERY USED IN THE UNITED STATES

1. Large tractor ploughing outfit of the northwest
2. Combination disc harrow, spike tooth harrow and grain drill preparing the soil and sowing grain in one operation
3. Four row corn planter hook-up on the University of Wisconsin experimental farm in 1926
4. General purpose tractor with a four row cultivator attachment, which cultivates 40 acres a day
5. Corn binder used on large farms in Middle Western States
6. Latest form of cotton picking machine, which has reduced marketing costs
7. Hay mower drawn by tractor
8. Side delivery hay rake which has improved the feed and speeded up hay harvesting
9. Modern hay loader, which simplifies and hastens hay loading

responding periods are from ten to twenty years later.) Obviously, attempts to intensify and diversify agriculture involved machinery and implements in no small way. Increasing land values must sooner or later force a greater return per acre; this is possible by increasing the production per acre or by lessening the cost of production, either one of which involves machinery and power.

The period opened with many of the most fundamental types of agricultural machinery well established. Minor improvements continued in all classes of implements. Sled corn harvesters, corn binders, and side delivery rakes to facilitate loading hay with hay loaders, came in early in the period. These were great labour savers. Inasmuch as one man with three horses on a two-row cultivator can cultivate 90% more acreage per day than one man with a single-row machine, it was only natural that attention should be given the two-row cultivators which began to appear early in the '90s. About 1890 the Babcock device and system was developed for determining the butterfat content of milk and cream. The Babcock test helps the farmer cull the unprofitable cows from his herd. Cream separators appeared about 1890, and a great labour saver—the milking machine—came into use about 1910.

Among the early attempts to adapt the internal combustion engine to farm work no efforts stand out more prominently than those of Hart and Parr, two young men who developed very satisfactory, stationary, gasoline (petrol) engines as early as 1896. A little later they conceived the idea of mounting a gasoline engine on a truck, and gearing the two together so that the combined unit would propel itself. In 1902 these men built such a machine and proved that the gasoline engine could be used for haulage purposes. A new industry—the great modern tractor industry—was born. Manufacture began almost immediately by several companies, and within nine years a large number of tractors were ploughing, harrowing, seeding and threshing in those regions of the United States and Canada where the farms and fields were large. These early tractors were large, heavy and somewhat crude. Being able to develop 30, 40 and sometimes 50 horse power at the draw bar, they pulled six, eight, ten and twelve-bottom ploughs, or large combinations of soil preparation and seeding implements. One single ploughing outfit, consisting of three large tractors pulling a 50-bottom plough, once demonstrated its ability to plough an acre of ground in 4½ minutes. The advent of the large tractor called for ploughs of size not known before, but manufacturers were quick to respond with the big, multiple-bottom gang ploughs of the independent lift type in which each bottom or each pair of bottoms raised and lowered independently of those adjacent. Larger, heavier disc harrows, and wider grain drills also were developed for the new "brute."

The tractor had demonstrated its ability to get work done quickly with a minimum of human labour, and, in farming, getting work done when weather, crop or soil is right is a decided advantage. The old heavy tractors, however, required considerable outlay in cash, and they were too unwieldy for practical use except in large fields. About 1910 the power farming idea had so thoroughly gripped agriculture that suddenly a demand for small tractors developed from farmers on smaller tracts, and many of the old manufacturers, together with a great number of new tractor concerns, began bringing out smaller tractors. This tendency to cut the size, power, weight and price continued until the light tractor of 8-16 and 10-20 horse power came onto the market about 1916 and brought with it the light, two-wheeled tractor plough which was quite an innovation in plough design. The light tractor and light plough, selling at prices which made their use economical on small farms, introduced power farming onto thousands of farms in both the United States and Canada which could not have enjoyed its advantages had not smaller, cheaper units been made available. Likewise, small sizes of grain threshers, of ensilage cutters and of feed grinders became popular because the presence of the small tractor on the farm enabled the farmer to perform these respective operations himself instead of having to depend upon the custom outfit which previously had passed from farm to farm doing belt work for hire.

Another major development in the current period of agriculture

is the mechanical corn picker. Such a machine was talked of in 1851; some were built and successfully operated about 1910, but not until about 1920 did it really start to take its place in the corn belt. Likewise, rotary hoes, for rapid corn cultivation, were in 1928 just beginning to become popular, although they had been on the market for 20 years. A new machine of importance to the sugar cane industry is the mechanical harvester which cuts, strips and bunches the cane in one operation. This is a big, expensive machine, but, when finally perfected, it will be a great labour saver.

Present Position.—Inasmuch as we are now in the midst of tendencies and developments in agricultural machinery which promise far reaching effects, it is well to consider the period since 1925 separately. Thus far the farm tractor has functioned well for ploughing, harrowing, seeding small grains and for belt work. The conventional type of tractor, however, has not been so well adapted to mowing and raking hay, or to planting and cultivating row crops. In such work not so much power is required; quick guiding and short turning are necessary, and the implement elements which perform the work must be so placed that the operator can readily see their action and easily manipulate them. What agriculture needed was a light tractor, perhaps of special form, which, in addition to ploughing, harrowing and doing belt work, could serve as a base for the quick attachment and detachment of such implement elements as an eight-foot cutter bar for mowing, a rake, hoppers for planting four rows of seed at once and cultivator rigs for cultivating those rows. Since 1925, general-purpose tractors of this type have proved successful and are becoming very popular. They are bound to have considerable influence in several kinds of farming and probably will cause rather marked changes in implement design. Another tractor development of importance is the power take-off, a device and system by which the tractor can drive directly the working parts of the grain binder, corn picker or combination harvester-thresher.

To-day the farmer of 200 acres can have his 15-30 horsepower, conventional type tractor for the heavy field and belt work; then he can resort to his general-purpose tractor for the lighter field and row crop jobs. The farmer of a tract too small to support two tractors can use his general purpose tractor for all tractor jobs. Either of these farmers can have a motor truck to haul

BY COURTESY OF THE J. I. CASE THRESHING MACHINE COMPANY

THE MODERN TWO BOTTOM TRACTOR-PLOUGH. FOR USE ON SMALL FARMS, DEVELOPED FROM THE BULKY 8 AND 12 BOTTOM TRACTOR-PLOUGHES THAT REVOLUTIONIZED THE FARMING INDUSTRY IN 1902

his produce to market, and both are sure to have an automobile. Thus, except in the poorer agricultural regions and in extremely hilly country, the slower methods by horses have received a severe setback.

The old process of loading manure by hand may give way soon to the mechanical manure loader now being developed. Mechanical shockers are on the market; they promise relief in the back-breaking task of shocking grain after the grain binder. Another development, however, threatens the grain binder. Since 1925 it has been found that combination harvester-threshers can be used successfully for small grain and soy-beans grown in humid regions, and several of these machines have been sold in the north central states, in western Canada, and even to a few large farms in the

eastern states. The appearance of this great labour saver in the smaller wheat fields of the upper Mississippi valley has been somewhat of a sensation. There, of course, smaller machines are used, the ten and twelve foot size now being most popular. The use of the "combine" means a saving of approximately 20 cents a bushel in the cost of raising wheat. The combination harvester-thresher is introducing another machine, the windrow-harvester, as an accompaniment to the "combine" in territories where uncertain weather, uneven ripening or the presence of a heavy growth of weeds require that the cut grain lay in the windrow a few days previous to threshing. The windrow-harvester, tractor drawn and tractor driven, cuts a wide swath of grain high, and lays it in a windrow on top of the stubble. After the material has cured, the "combine" is used to pick up and thresh the windrows.

From the standpoint of cost of production, a mechanical means of picking cotton has been needed and sought for many years. Not until quite recently, however, have efforts to produce a practical device been successful enough to promise early relief. One type of cotton picker consists of a number of revolving spindles which pluck the cotton by wrapping it about them as they turn; the spindles then recede to a cleaning chamber where the cotton is removed ingeniously, and the spindles automatically return to come in contact again with the plant. The action is continuous as the machine straddles the row. Such pickers, although they are not quite to the manufacturing stage, seem very promising for territories where uneven ripening necessitates several pickings. Where killing frosts occur before picking time, as in north-western Texas, manufacturers are now marketing cotton strippers. These strip the cotton from the plant, and are much simpler and cheaper than the typical, mechanical picker. This method of harvesting has become practical only since improvements in ginning machinery have made it possible for the ginner to handle the great amount of trash and bolls which the stripper gathers. Since 1925, renewed attention has also been given to the application of electricity to agriculture. For this see ELECTRICAL POWER IN AGRICULTURE. As to the farm home, one need only liken the application of electricity there to that in the most modern city dwelling.

From this brief historical sketch we see that through the introduction of agricultural machinery and implements the muscular exertion of farm work was slowly shifted from man to beasts of burden. These in turn have been displaced by mechanical power units and by more machinery until to-day, comparatively speaking, agriculture seems well mechanized. The same is true in all industry; but the benefits of the transition in farming are especially significant because in agriculture there is more primary horsepower involved than in all manufacturing and mining combined. With the cheap fertile lands of the United States and Canada largely utilized, with fertility being depleted, with the population increasing rapidly, more intensive agriculture that will increase production per acre seems sure to come. But, again, this involves machinery in no small way if increased production is to be had without marked increase in costs. If the farmer is to maintain his standard of living, and at the same time successfully meet competition in the world's markets, he must pay increasing attention to the many phases of agricultural machinery and implements.

Manufacturing.—As indicated in the following table, taken from United States census reports, the value of machinery and implements on farms has increased rapidly until to-day it aggregates a large investment. It is to be noted, too, that capital used in the manufacture of agricultural machinery indicates an extensive industry.

Between 1900 and 1910, several large combinations of manufacturers were effected in order to pool interests, to secure "full lines" of merchandise, and to lessen the expense of development and sales work. This introduced a new era in the manufacture and sale of farm equipment. The manufacturer's problem to-day is not one of new developments alone. The merchandising of farm machinery and simplification of types are also vexing problems, and in these the manufacturer is handicapped by the farmer

Census year	Value of machinery and implements on farms in the United States	Manufacture of Agricultural Machinery		
		Number of establishments engaged in	Capital invested in	Value of manufactured products including goods exported
1850	\$ 151,587,638	1333	\$ 3,564,202	\$ 6,842,611

himself. Developing and introducing a new device calls for peculiar talent and is often a greater task than simply patenting the idea. In addition to commending the thousands of inventors who contributed to the development of agricultural machinery, much credit is due also to such men as McCormick, Deering, Osborne, Wood, Deere, Parlin, Emmerson, Noyes, Brown, Adams, Steward, Oliver and a score of others, the pioneers in manufacture. It was to the vision, persistence, and the business, organizing and manufacturing ability of such men that the industry owed its foundation.

AGRICULTURAL ORGANIZATION. In most countries a growing realization of the weakness of the isolated farmer as a marketing unit and, again, of the dominance of industrial and commercial interests in modern legislation has prompted the formation of farmers' organizations, in order to secure more adequate consideration of the position and needs of agriculture. The conditions of food scarcity brought about by the World War stimulated this movement. (See AGRICULTURE.) Governments were obliged to deal collectively with the primary food producers, who on their side were forced into combinations to secure that the necessary regulations neither impeded production nor imposed an impossible burden on the farmers. Combinations for marketing are dealt with elsewhere (see AGRICULTURAL CO-OPERATION); the organizations here to be considered aim at uniting the farming community in order to influence legislation.

Further, since it has become clear that the status of the food producer can with difficulty be determined within the nation itself, considerable effort has been given to the formation of international associations which might be able to secure common action in the interests of agriculture. It is recognized that as regards the great staple articles of food, wheat and the other cereals, meat and dairy products, a common world price tends to be set, determined by the incidence of the exportable surpluses from the countries producing more than they consume, upon the chief open markets, e.g., Great Britain. For example, the United States produces a certain excess of wheat beyond its requirements, which has to be exported chiefly to Europe. The price the American farmer will receive will be forced down by competition to the price obtainable in Europe less freight and commission. This is, to take an analogy, the pressure generated by internal competition to sell, at which the safety-valve blows off. The coincidence of other surpluses upon the European market or weakness in purchasing power there tends to lower the price; conversely the growth of a new demand, as from China and Japan, will enhance the price.

The tendency of commerce is generally to bring the run of prices of agricultural products, the output of which fluctuates from causes beyond control, continually down to the level caused by a surplus anywhere, a level which is on the average undesirably close to or even below the cost of production. Hence a general depression of the agricultural interest all over the world and an increasing tendency on the part of farmers to seek more remunerative occupation in industry or commerce. This is the justification for the attempts to create some international organization of farmers, however remote and impracticable common action may seem.

National Organization.—Examples of the type of national organization which aims at influencing legislation are the National Farmers' Union of Great Britain, the Farm Bureaus Federation and The Grange in the United States, and the Union Suisse des Paysans, but parallel organizations exist now in most countries.

The National Farmers' Union was only founded in 1908 and grew comparatively slowly until 1917, when it became necessary for agriculturists to have one organization to deal with the Government on behalf of the farmers engaged in the campaign for the increase of food production. It is organized on a basis of county branches, each of which makes an allotted contribution to the central body; only men actually engaged in farming are accepted as members. By 1927 the membership had reached 130,000, farming an area of some 12,500,000 acres. A similar Society exists in Scotland.

One of the most notable organizations in Europe from the point of view of the influence it has been able to exert is the Union Suisse des Paysans of which Dr. E. Laur is the director.

Its membership includes nearly all the farmers in Switzerland, though the only figure available, 402,000, is the sum of the membership of all the affiliated societies, and the same individual may be a member of several of these simultaneously. It enjoys a subscription income of upwards of 100,000 francs a year. The oldest of the organizations in the United States is The Grange, or Patrons of Husbandry, which was founded in 1868 for educational and social purposes. Later it became active in political life and in organizing marketing agencies.

More recently the Federation of Farm Bureaus grew up among the Farm Bureaus which were initiated for educational purposes by the County Agricultural Agents. It is now a widespread and active organization, exercising considerable influence both as regards marketing and legislation.

International Organization.—The International Institute of Agriculture, the original conception of which was due to the late David Lubin, though it took shape on the initiation of the present king of Italy, began operations in 1910. Its constitution is determined by treaty between the contributing States, and it is governed by a president and a permanent committee acting as the executive authority to carry out the instructions given by an assembly representative of the constituent States, sitting every two years in Rome, where the Institute has its permanent home. The representatives at the assembly and on the permanent committee are nominated by the respective governments; thus the Institute is essentially a governmental organization, in which agricultural associations as such have no part. The work of the Institute has always been of a technical character. It prepares an annual summary of the agricultural statistics of all countries and a digest of agricultural legislation; it also issues bulletins at regular intervals which abstract the papers appearing in the technical publications of the world on economic and scientific subjects connected with agriculture. The Institute also convenes from time to time international conferences on particular questions. In order to obtain an expression of international agricultural opinion that shall be independent of governments the Institute has formed an association of representatives of agricultural associations of all countries, and the first meeting of this body was held in Nov. 1927. The associations to be invited to send representatives are, however, nominated by the governments of the respective countries. It has been urged that the international body which is to express the considered opinion of agriculturists must be independent of all governmental control or direction, especially as regards the nomination of representatives or associations to be represented.

To this end the Commission Internationale d'Agriculture, a body founded in 1891, of which the chief task was the organization of the successive International Congresses of Agriculture, has been reconstituted to consist of representatives of agricultural associations (not exceeding six for each country) and of co-opted members of distinction in agriculture, which latter may take part in the discussions but not vote. While the Commission meets twice a year in Paris, the resolutions that are to be communicated to governments are reserved for discussion at a conference to be held every second year in connection with the International Congress of Agriculture, of which conference only the elected representatives of the associations are members.

On the formation of this Commission, which held its first meeting in Rome in 1927, various other proposals for the establishment of an international association of agriculturists, e.g., that initiated by Dr. Laur of Switzerland, were dropped. Eighty associations from 22 different countries including all the European States except Great Britain and Italy, have adhered, and the Commission has entered into relations with the League of Nations and the International Institute of Agriculture at Rome. The Commission may be regarded as possessing the best title to express the considered opinion of the agriculturists of the world, and it may be hoped that it will also be accepted as the Conference of Associations working with the International Institute at Rome.

(A. D. H.)

AGRICULTURAL PRICES. In the early stages of English agriculture the mass of producers were content to satisfy

their own wants and were practically indifferent to outside trade. Later, however, the need arose for some machinery for bringing buyers and sellers into touch, and this was met by the institution of fairs and markets held at fixed places and periods. These in the first instance no doubt arose spontaneously, but it speedily became apparent that the holding of a fair or market in a town could be made a source of profit to the burgesses, or if there were no sufficiently powerful organized community, to the lord of the manor. Thus arose a system of tolls on goods exposed for sale in the market. The Crown, exercising its authority as overlord, saw at once an opportunity of revenue and claimed and exercised the right to forbid the holding of a fair or market except under royal charter, which was granted on terms. Tolls and regulations of the market would tend to raise the price level, but the effect could only have been slight.

A more serious effect on agricultural prices was caused by legislation against the practices of badgering, forestalling, engrossing and regrating, which was passed in the early part of the 16th century and did not disappear from the statute book until late in the 18th century. The purpose of this legislation in restraint of trade was to protect the consumer from trade practices which were presumed to raise artificially the price of food. A "badger" was a dealer in food who bought in one place and sold in another. He was licensed for a year and was under recognisances against forestalling, engrossing and regrating. "Forestalling" was purchasing food on the way to market with intent to sell it at a higher price; "engrossing" was attempting to control—in modern phraseology to "corner"—the market by buying up all the food for the purpose of exacting higher prices; "regrating" was the resale of food previously bought in the same market.

The State for many centuries intervened directly in the regulation of the price of wheat and bread. From the Norman conquest to the reign of Henry VI. the exportation of wheat was prohibited, although in earlier times it had been common. Importation was unchecked, although there is no record of it until the 14th century. In 1436 an act was passed authorizing the exportation of wheat whenever the price did not exceed 6s. 8d. per quarter and in 1463 the exportation of corn was forbidden until the price exceeded that at which exportation ceased. Thereafter a succession of enactments were passed some giving a bounty on exports, others imposing a duty on imports, or adopting both methods under limitations of prices. In 1774 an act was passed permitting imports at a nominal duty of 6d. per quarter when the price reached 48s. and forbidding exports unless the price was below 44s. when a bounty of 5s. per quarter was given on exports in British ships.

Up to this time legislation had for its main object the interests of consumers while attempting also to have regard to the interests of producers, and also to encourage shipping. In 1791 the first of a series of acts was passed which, with increasing stringency, aimed mainly at protecting the interests of home wheat-growers, which continued until the repeal of the Corn Laws in 1846.

In the 13th century the Assize of Bread was established, by which the duty was imposed on justices of the peace of adjusting the weight, quality and price of bread to the current prices of wheat. The system was modified in detail from time to time, but continued in force until 1822 in London and until 1836 in the provinces.

Modern Methods.—In later times the establishment of great markets in the large centres of population did much to fix prices on the basis of general and not of local supplies. Many of the markets developed from local to national importance by reason largely of their position in relation to means of communication. Covent Garden is a notable instance. It was originally a place where growers of fruit and vegetables in the vicinity of London could dispose of their produce direct to retailers and consumers. The convergence in the metropolis of the main lines of railway made it a national distributing centre, serving, through various channels, all parts of Great Britain, and "Covent Garden prices" became the standard of values throughout the country.

The organization of commercial price-fixing on a national basis had, however, scarcely been completed when a new factor was interposed which speedily changed the basis on which price-levels

of some of the principal foodstuffs rested. Imported wheat, meat, cheese, butter and other kinds of agricultural produce were sent to the British markets in ever-increasing quantities. As they increased in bulk and improved in quality their influence became so great that prices in the wholesale markets were fixed on an international rather than on a national basis.

The most prominent instance of this modern development is to be found in the wheat trade, where imported grain, forming as it does about four-fifths of the whole supply, dominates British prices and determines the value at any given time, of British wheat.

Price-fixing arrangements in the wheat trade are highly organized. World's prices are practically settled at four great markets, viz., Chicago, Winnipeg, Liverpool and London, and so well adjusted and sensitive is the mechanism that fluctuations in one are immediately reflected in the others.

The question of the effect on prices of the system under which the world's wheat trade is carried on is debatable and has been, in fact, hotly debated. It has been contended that speculation in "futures" depresses the level of prices and thus injures farmers, and, on the other hand, that it raises the level and thus injures consumers. The subject has been investigated closely, and it appears, by comparison with the price records of other commodities, that, on the whole, the organized "futures" market tends to maintain a more stable level of prices, notwithstanding occasional fluctuations caused by gambling operators.

The "stabilization" of agricultural prices is advocated in some quarters, but no intelligible scheme has been produced which does not imply State control and an acceptance by the taxpayers of the risks of State trading.

Yearly, or seasonal, fluctuations of agricultural prices are, as already indicated, occasioned mainly by variations in the weather, but there are also cyclical changes which are the result of monetary causes. Periods of low prices react not only on agricultural products but on all other commodities, and a consideration of them requires a wider outlook than that presented by one branch of production.

Price Records.—Of the price of British wheat there are consecutive and fairly comparable records for nearly 300 years.

The average prices per quarter for each decennium since 1647 are as follow:—

	s.	d.		s.	d.
1647-56	52	8	1787-96	54	4
1657-66	51	4	1797-1806	76	9
1667-76	42	4	1807-16	91	0
1677-86	42	2	1817-26	67	0
1687-96	43	2	1827-36	56	1
1697-1706	40	1	1837-46	58	7
1707-16	47	7	1847-56	55	4
1717-26	36	3	1857-66	48	6
1727-36	35	8	1867-76	54	3
1737-46	32	10	1877-86	42	3
1747-56	34	9	1887-96	29	2
1757-66	40	9	1897-1906	28	5
1767-76	49	9	1907-16	37	6
1777-86	44	5	1917-26	61	10

The highest price for any single cereal year was 126s. 6d. in 1812, and the lowest 22s. 10d. in 1894. The highest price in the last decennium was 80s. 10d. in 1920, and the lowest 42s. 2d. in 1923.

Systematic records of food prices were begun by Sauerbeck in 1846 and the series is continued in the *Statist*. Similar records have since been started by the *Economist* and the Board of Trade. In 1904 the British Board (now the Ministry) of Agriculture began to collect and publish weekly a market report which includes prices of all agricultural products.

By the method of index numbers these records enable the changes in the prices of agricultural products to be compared with those in the prices of commodities generally. There was a fall in prices generally between the periods 1871-75 and 1894-98 which averaged 40%. In the period from 1894-98 to 1910-14 there was an average rise in the prices of all commodities of 33%. The changes in the prices of British agricultural products in these two periods are indicated in the table given overleaf:

	1871-75 to 1894-98	1894-98 to 1910-14
	Fall per cent.	Rise per cent.
Wheat	51	22
Barley	39	13
Oats	38	19
Potatoes	39	10
Pork	23	23
Beef	29	26
Bacon	25	29
Mutton	25	20
Butter	25	25

After 1914 prices of agricultural products, as of other commodities, rose rapidly under war conditions. Taking the period 1911-13 as the base, the average percentage rise in each year is shown below, the rise in the price of feeding stuffs and fertilizers being also given:

Year	Agricultural products	Feeding stuffs	Fertilizers
1915	27	37	15
1916	60	87	56
1917	101	174	96
1918	132	187	111
1919	158	168	115
1920	192	173	159
1921	119	81	120
1922	69	46	47
1923	57	36	23
1924	61	54	19
1925	59	52	14
1926	51	25	13

(R. H. R.)

United States.—The great rise in commodity prices caused by the World War and the consequent post-war decline had grave economic consequences throughout the world. One of the distinguishing features of that international price upheaval is that during the period of rising prices, agricultural prices advanced more, whereas during the period of falling prices they declined more than did other prices. The nature of this post-war price disparity can be well illustrated with the price changes that took place in the United States, where the effect of agricultural price depression was not limited to the business depression of 1921 and 1922 but continued as a political factor for several years thereafter.

According to the indexes of the U.S. Bureau of Labor Statistics, commodity prices reached a peak in 1920. In that year, they were, in general, on the average about 130% higher than during the pre-war five-year period, 1910-14. Agricultural prices were about 121% higher and non-agricultural or industrial prices about 141% higher.

Prices received by farmers at their local farm markets had also advanced in line with the advance in agricultural prices at the central markets. Then came the great price decline of 1920-21. The unequal effect of that price decline can be seen in the indexes for 1921. All wholesale prices taken together dropped 80 points, non-agricultural prices dropped 74, but agricultural prices dropped 88 points and prices received by farmers 89 points. Because of this greater decline in agricultural prices, the general depression of 1920-21 became an agricultural depression of longer duration.

The sudden deflation in the value of the farmers' products affected all sections of the agricultural industry. Land values were high, many had purchased farms at high prices, burdened themselves with heavy mortgages and expected the high prices of 1920 to continue. On practically all farm-land taxes had more than doubled, and other expenses of production, such as wages and machinery, had also risen. When in 1921 prices crumpled to half or less of those prevailing in 1920, the necessity of meeting the fixed high interest and rent charges, as well as the high production costs, left very little, if anything, of income available for living expenses. Furthermore, the higher prices of goods

bought by farmers (as shown by the index of non-agricultural prices) reduced the buying power of the farmer still more. The low and inadequate farm incomes of 1921 and 1922 naturally also hurt those undertakings dependent on agriculture, such as country banks, country stores, fertilizer and implement agencies. As a result of many causes, partly domestic, partly foreign, agricultural prices did not recover materially in 1922. Since then, first one farm commodity, then another, has, usually as a result of reduced production, recovered temporarily, but in the main agricultural prices have remained nearer the pre-war prices than did the non-agricultural prices throughout the period 1921-27. About this agricultural and non-agricultural price disparity has centred much of the discussion of farm relief. The removal of that disparity by raising the level of agricultural prices to that of industrial prices and creating a greater degree of stability in agricultural prices has been the object of practically all proposals for farm relief, particularly the McNary-Haugen plan which has been before the U.S. Congress in several modifications for four years; twice passed by both Houses and twice vetoed by the President.

Briefly described, the McNary-Haugen plan of farm relief provided for the establishment of a Federal Farm Board with power so to buy and sell surplus farm products of the United States as to raise the domestic prices received by producers. The cost of operating the plan and any losses sustained in the sale abroad at prices lower than in the United States would be met by a fee known as an "equalization fee" collected at the central markets from mills, packers, etc., on all units of a commodity that entered commerce. In that way all producers would contribute alike to the cost of the plan, and all would share alike in the benefits of the difference between the advance in domestic prices and the fee collected, the advantage arising from the fact that far more would be sold in the domestic markets at higher prices than would be sold at lower prices abroad.

In its early form, as voted down by Congress in 1924, the McNary-Haugen plan aimed to equalize agricultural and other prices by setting up a Federal agency to handle the surplus production of crops which were held to be responsible for maintaining agricultural prices on a low level. The general level of all commodity prices, which was then approximately about 150% of the pre-war level, was to be used as a standard. The operations in Government buying and selling were to aim toward raising individual farm commodity prices to the general wholesale level of all other commodities. This price-ratio scheme was dropped in favour of a plan to make the tariff effective, the emphasis of the latter growing out of the belief among farm leaders that the stability of non-agricultural prices was the result of protective measures enjoyed by other groups, such as existing tariffs on non-farm products, immigration-restriction law, aiming among other things to maintain high wage standards, and the Federal Reserve system aiming toward stability in finance and commerce.

The emphasis on "making the tariff effective for agriculture" was not maintained in the later forms of the McNary-Haugen plan because a tariff could protect only those farm products of which the domestic production was below domestic requirements. In the case of commodities such as cotton and tobacco, the major part of which the United States exports, tariff protection could not raise prices to a higher level or prevent annual fluctuations.

Originally the McNary-Haugen proposal found most of its support in the west central farm sections of the United States where grain and livestock prices remained low until the summer of 1924. Other sections of the country, such as the dairying and the southern cotton producing areas, gave it little support. Prices for their products were either not particularly low or were actually high, as was the case with cotton. But in 1926 a record cotton crop created a cotton-price depression as serious as that of 1921, which had the effect of bringing southern farm leaders to the support of the McNary-Haugen plan. This wider support, which may be said to have grown out of the low grain and hog prices up to 1924 and out of low cotton prices of 1926-1927, resulted in the passage of the McNary-Haugen bill in the spring

of 1927. Vetoed by the President, it was again passed by both Houses of Congress in 1928, and again vetoed on the grounds of impracticability, unconstitutionality and class legislation. See **FEDERAL FARM BOARD.** (L. H. B.)

AGRICULTURAL PRODUCTION: see **AGRICULTURE**, **CENSUS OF**, and the various products, **WHEAT**, **BEEF**, etc.

AGRICULTURAL RESEARCH. In its modern aspects agricultural research began with the series of field experiments started by Jean Baptiste Joseph Dieudonne Boussingault about 1834 on his farm at Bechelbronn, in Alsace. He had already made a name as an adventurous traveller in South America, but at the age of 32 he settled down to field experiments which he carried on until Alsace passed into the hands of the Germans. Unfortunately the farm was not preserved, and in consequence this first experimental station has long ceased to exist.

The scientific foundations had already been laid by the de Saussures, Jean Senebier, and other plant physiologists of the Geneva school and elsewhere, and considerable information had been gained by Sir Humphry Davy; but these results could not be interpreted in field terms without field experiments. Boussingault used quantitative methods; he weighed and analysed the manures applied and the crops obtained and at the end of the rotation drew up a balance sheet showing how far the manures had satisfied the needs of the crops, and how far other sources of supply, air, rain, and soil, had been drawn upon. This method, patiently and carefully applied, solved the problem of the feeding of crops, and it remains the basis of all modern field work. The facts gathered by this and other methods were reduced to order by Justus von Liebig in 1840 and subsequent years in his brilliant generalizations on plant nutrition and crop production.

In 1843 J. B. Lawes and J. H. Gilbert started their experiments at Rothamsted, which are still carried on, so that Rothamsted remains the oldest agricultural station in the world. These experiments led almost immediately to the discovery of artificial fertilizers, the effects of which on the soils of Britain were so striking that similar experiments were soon made in most countries where conditions were sufficiently settled. Although the results were not always as clear and definite as in Great Britain, the experiments opened the way to new knowledge of soils, crops, and animals; in the United States, where water supply is often the limiting factor in crop production, they led to important developments in soil physics; in France, to George Villes' important contributions on the use of fertilizers; in Russia, to far-reaching studies of soil morphology.

Soil bacteriology (*q.v.*) began in France as the result of an investigation by J. T. Schloessing and C. A. Müntz; further fields were opened up by P. E. M. Berthelot. Striking advances were made by Sergei Winogradsky, who introduced new conceptions and more precise methods, raising the subject to the rank of a science. Animal nutrition was studied first by Lawes and Gilbert at Rothamsted and then considerably developed in Germany. Right up to the time of the World War there was continuous expansion; agricultural colleges and experiment stations were founded in almost every civilized country, and notable contributions to agricultural science were being made not only in the larger but in the smaller countries, Holland, Denmark, Switzerland, Sweden and others.

Since the War there have been many and striking developments. Although impoverished, the European countries have maintained and even extended their organizations for agricultural research, and in every country except one or two in south-eastern Europe there are experiment stations owned and financed by the State; frequently also others financed by agricultural societies. Indeed, the belief of the modern farmer in agricultural education and research is one of the most hopeful features of the times.

The British Empire.—For many years the great self-governing Dominions have had their own agricultural research stations which have made notable contributions to agricultural science. The Canadian workers have achieved much in the production of new varieties of wheat, the farming of dry lands, and the development of agricultural machinery.

The Guelph Agricultural college had been founded in 1873 but

it grew only slowly and in 1883 it had only nine graduates. Then came the awakening of Canada to the need of agricultural research. In 1884 a select committee was appointed by the Canadian parliament to study agricultural conditions and this committee recommended the establishment of an experimental farm. In 1887 this was done, and the farm was started near Ottawa under the direction of William Saunders. It has since grown out of all recognition and has now become one of the foremost agricultural experiment stations in the world. Branch farms were established in different parts of the Dominion, some of which, such as Indian Head (Sask.) and Lethbridge (Alta.), have by reason of their special conditions been able to carry out researches which could only with difficulty have been achieved elsewhere. The present director of the Ottawa station is E. S. Archibald, who succeeded J. H. Grisdale, the second director, in 1916.

Australia has, in Farrar's wheats and many field experiments, done much for arable farming and the solving of pastoral problems; still more recently the setting up, at Adelaide, of the Waite Agricultural Research Institute in 1923 under Dr. Richardson, and of the Department of Scientific and Industrial Research under Dr. Julius, have opened up great possibilities of future development. In New Zealand the Cawthron Institute was established at Nelson in 1915; South Africa has probably the largest and best veterinary research station in the world at Onderspoort under Dr. P. J. Du Toit. In India the large experiment station at Pusa was started in 1903 by the aid of a generous gift by Mr. Phipps, an American. In other tropical regions there have been very great developments. The Imperial College of Tropical Agriculture was founded in 1924 at Trinidad to give the training which could not be provided at home. The research institute originally founded by the Germans at Amani in Tanganyika has been restarted since the World War under the directorship of Dr. Nowell. The Wellcome Tropical Research Laboratories at Khartum are maintaining and extending their studies of soils and micro-organisms, important in tropical conditions, and each of the African territories has its own agricultural officers. Perhaps even more significant, the growers are organizing and financing their own experiment stations on broad and generous lines that augur well for the future: the Rubber Research Institute of Malaya, inaugurated in 1926; the Tea Research Institute of Ceylon, inaugurated somewhat earlier, are examples. Altogether the progress of agricultural research in the empire in the post-War period has exceeded the most sanguine expectations.

Until recently, each of the separate parts of the empire conducted its own researches independently of the rest. In Oct. 1927, however, an imperial agricultural research conference was called for the first time and the first steps were taken towards co-operation and co-ordination so far as this might be possible. It was decided to set up bureaux in Great Britain, for soil at Rothamsted, animal nutrition at the Rowett Research Institute, Aberdeen, and animal health in London; also correspondence centres for plant genetics at Cambridge and Aberystwyth, fruit at East Malling, animal genetics at Edinburgh and agricultural parasitology in London; these are in addition to the already established bureaux for entomology and mycology; while a further object that they have is to keep in touch with all agricultural research workers in the empire, provide information, and generally give any further help in their power.

Great Britain.—In 1909, parliament set up the development fund at the instance of Mr. Lloyd George and assigned a capital sum of £2,000,000 for rural development, including agricultural education and research. The commissioners adopted a novel method of organization of research which has fully justified itself. Instead of setting up one or two large stations to deal with the whole body of agricultural science they made grants to certain existing institutions, each of which was to become responsible for one or more sections of agriculture. Of these institutions the chief are:—

Soils, plant nutrition, and plant pathology.

Animal nutrition.

Rothamsted experimental station.
Cambridge university.
Rowett Research Institute,
Aberdeen.

Plant physiology.	Imperial College of Science and Technology, London.
Plant breeding.	Cambridge university. University college, Aberystwyth. Scottish plant breeding station, Edinburgh.
Fruit.	Long Ashton, Bristol. East Malling, Kent.
Glasshouse industry.	Cheshunt, Herts.
Animal breeding.	Edinburgh university.
Dairying.	Reading university.
Animal pathology.	Cambridge university. Royal Veterinary college, London. Scottish Animal Diseases Research Association.
Agricultural parasitology.	London School of Hygiene and Tropical Medicine.
Agricultural economics.	Oxford university.
Agricultural engineering.	Oxford university.

The amounts expended on agricultural research in Great Britain have increased continuously since 1909, the original development fund having been substantially increased when the Corn Production Act was repealed and the State commitments were commuted by the grant of £1,000,000 which, at the request of the farmers themselves, was devoted to agricultural research and education. In 1926 the grants amounted to £329,705, including £60,000 advisory, £9,231 rural industry, and £23,700 Scottish grants. The total research grant for England and Wales was therefore £236,774. Besides the State funds, grants are periodically made to institutions by the agricultural societies.

The United States.—Agricultural research began early in the United States. On Feb. 26, 1791, there was held at the senate chamber, New York, "a meeting of a respectable number of citizens" which established a society for "the investigation of agriculture, manufacture, and arts, with such subjects of enquiry as may tend to explain or elucidate their principles." In 1842 a successor, the New York State Agricultural Society, began the publication of a series of reports, some of which, dealing with the design of the plough, are among the best that have yet been written on the subject. Faith in agricultural education in the United States was so great that even during the anxious days of the Civil War Senator Justin S. Morrill, of Vermont, was able to persuade the legislature to adopt the Act which bears his name, and which was signed by Abraham Lincoln on July 2, 1862; this established in each State a college of agriculture and mechanical arts that often developed in conjunction with a State university. Information regarding the agricultural colleges in the United States and their work will be found in the article AGRICULTURE IN THE U.S.A.: *Experiment Stations*.

The Federal Department of Agriculture, created by an Act of Congress and signed by President Lincoln in 1862, is the most extensive agricultural research agency ever established, its work covering every field of agriculture and rural life affairs. Through its Office of Experiment Stations it has general supervision of the State Experiment Stations, with which it carries on a large number of co-operative investigations. Its great research bureaus expend over ten million dollars a year in fundamental investigations in addition to about the same amount expended by the Experiment Stations, making a total annual expenditure for research of over twenty million dollars. Recent estimates of financial returns for these expenditures published by the United States Department of Agriculture show that each dollar thus expended yields an annual return of over five hundred dollars. This explains in part the increasing support given to this type of work. There are also a certain number of private establishments. Some of these have become merged in the State institutions, such as the experiment station at Storrs, Conn., which, founded as an agricultural school, became a college and then, through the activity of one of its most distinguished members, Atwater, an important centre of research. Of the newer institutions which still retain their indi-

viduality perhaps the most notable is the Boyce-Thompson, founded in 1924.

Enormous sums of public money are expended in the United States on agricultural research. In 1925 and 1926 the amounts included:

	1925	1926
Federal Funds	\$10,000,000.	\$10,300,000.
Hatch, Adams and (in 1926) Purnell Acts	1,440,000.	2,400,000.
State appropriations	5,827,871.	6,000,000.
	\$17,267,871.	\$18,700,000.

In 1927 the total spent was \$21,000,000.

Some of the experiment stations are in receipt of large total incomes: in 1925 Ohio received \$736,164 and California \$665,861. But great as these sums are, they represent only six cents per acre per annum of the cultivated land in the United States and thus they are relatively not much greater than the expenditure in Great Britain, which represents four cents per acre; per \$1,000 of farm produce obtained each year the United States spends on research \$2.50 while Great Britain spends \$1.40.

France.—To France, as already described, belongs the honour of having begun the first field experiments. The college of agriculture at Grignon, founded in 1827, continues its activities. George Villes' experiments from 1848 to 1863 were made at Vincennes; Grandeau's at the Station Agronomique de l'Est founded at Nancy in 1871 and still associated with soil investigations. The experiment station at Montpellier is associated with vine investigations and with the soil studies of Delage and Lagatu. The chief organization in Paris is the Institut Agronomique; but the Institut Pasteur, although not an agricultural body, carries on researches in plant physiology and microbiology of great importance to agriculture, supplemented by the work at its sub-station at Brie-Comte Robert. It is hoped at an early date to develop a great national institute for agricultural science near Paris.

Germany.—Although the agricultural college of Hohenheim was founded as far back as 1817, there was no experiment station till 1851, when one was started at Möchern in Saxony under Emil Wolff. Others were set up later; at Munich in 1857, where much work was done on soils, and at Popplesdorf, where there had been an agricultural high school since 1847. There was a rapid expansion after the federation of the German States in 1871; in 1861 there had been only nine stations, but by 1881 there were at least 53. Most of these were attached to universities and under close Government control; they were also charged with certain responsibilities in regard to control of fertilizers, feeding stuffs, seeds, etc. Some, however, were under the agricultural societies. In 1888 the association of experiment stations was formed for the purpose of securing uniformity in methods of investigation and inspection of these various articles.

By 1914 the German experiment stations had much further increased, both in number and in size, and had attained great repute all over the world. There has, however, been some change in subject matter; much more attention is now devoted to fertilizers in consequence of the enormous strides in the output of synthetic nitrogenous compounds. Among the larger State institutions are those at Halle for animal nutrition, agricultural chemistry and microbiology; at Königsberg i. Pr., Bonn-Popplesdorf; Landsberg (Warthe) for soils, plant nutrition, animal husbandry, and plant pathology; at Bremen and Landsberg for moor culture; at Breslau, Hohenheim and Göttingen for agricultural chemistry and bacteriology; at Berlin and Leipzig (Möckern) for many branches of agricultural science. In addition to these, there are great private institutions owned respectively by the nitrogen syndicate, the potash syndicate and the superphosphate manufacturers' association.

Russia.—The Russian experiment stations have been completely reorganized since the revolution. Those best known to the outside world devote much of their time to soils; those deserving mention are:

Perm	University biological Station
Voronezh	Agricultural institute
Gorki (White Russia)	Agricultural academy

Leningrad.	Dokuchaiev Institute of Soil Science. State Institute of Experimental Agronomy.
Moscow.	Scientific Institute of Fertilisers.
Kazan.	Forestry and Agricultural Institute.
Saratov.	Institut für Landwirtschaft und Melioration.
Ukraine.	
Kiev	Forestry and Agricultural Institute.
Odessa.	Agricultural Institute.

Holland.—Of the smaller countries Holland deserves special mention because of the admirable research work carried out in Dutch East Indies at Buitenzorg in Java, the experimental gardens and station of which are models of efficiency and activity. The results are published in *The Bulletin of the Botanical Garden*. In Holland itself there are several well-known stations, the largest of which is at Wageningen, known, among many other things, for the work of Quanjér on plant pathology, Hissink on soil, and others.

Italy.—Italy possesses agricultural stations at Rome, Pisa, Turin, Portici, and elsewhere: the scientific results are published in *Le Stazioni sperimentali agrarie Italiane*.

Denmark.—Serious agricultural research began in Denmark after the termination, in 1864, of the war with Germany. The Danes sought, in the words of one of their distinguished statesmen, "to gain within their borders what they had lost without," and they proceeded to intensify their agriculture, developing a system which has become the admiration of Europe. One of the first stations to be set up was the veterinary and agricultural high school in Copenhagen, which from 1860 onwards published a series of admirable reports on the feeding of farm animals. As it expanded it covered other subjects of agricultural importance. Since the war agricultural research has developed considerably in Denmark. The method has been to set up a number of stations, each dealing with specific subjects; at the same time to establish field experiment stations in various parts of the country, all these being directly under the State. The veterinary college remains the centre for animal husbandry, forestry, and horticulture; it is, however, primarily a teaching institution. The more important of the newer research stations, which may be regarded as offshoots from Copenhagen, are at Lyngby and Hillerød, North Seeland.

Practical Results of Research.—The chief characteristic of the work of the experiment stations in recent years has been the tendency to joint investigation. Not only have stations in the same country combined to carry out a programme of work, but even stations of different countries. In the western United States and Canada there is a combined programme of investigation on wheat rust. In Europe the chief soil investigators have co-operated with those of Great Britain in devising uniform methods of soil examination and soil mapping, under the aegis of the International Society of Soil Science. The International Institute of Agriculture at Rome has brought together the investigators concerned with fertilizers, with the view of drawing up uniform methods of studying the action of these substances on the plant and on the soil.

Much of the knowledge recently gained at the experiment stations can be appreciated only in relation to the whole subject with which it is concerned, and is therefore dealt with under the proper headings. Some of the outstanding results are, however, referred to here. In the study of soils the most important advance has been in the knowledge of the changes taking place when salts are added to the soil. In principle the changes are simple, being merely the usual exchange of bases and acids; the consequences of these changes, however, are often far-reaching and they have been found to explain many of the phenomena of acidity and alkalinity, and also the deterioration of irrigated land. These phenomena were always taken to be quite independent, but now they seem to be closely related. With fuller knowledge of the causes the possibility is opened up of designing effective methods of treatment. A better knowledge of soil biology is opening up a new chapter in the field of soil formation and fertility.

Great progress is being made in the field of soil amendments and fertilizers, especially as regards the use of concentrated fertilizers.

Another striking development has been the recognition of the Russian work, which has been slowly developing during the last 40 or 50 years. This had been published in Russian and only briefly summarized in western languages, so that it remained inaccessible to western European and American students. In 1909 Dr. Glinka expounded some of this work to the European soil investigators assembled at the soil conference in Hungary, and in 1922 Dr. Waksman, at the request of the United States department of agriculture, translated many of the Russian papers into English. Soil workers then found a great mass of knowledge in regard to classification of soils, which was new to them. The basis of the Russian classification is that the soil type is largely determined by the environmental conditions; indeed it can be predicted once these are known. The recognition of this dependence has revealed the close relationship between climatic and orographical factors with soil type, which knowledge promises greatly to simplify the work of the soil surveyor.

Great advances are being made in the study of diseases of animals and plants, especially those carried by insects and mites, such as the tick fever, discovered by Theobald Smith of the U.S. Department of Agriculture, and the mosaic or virus diseases carried by plant lice and leaf hoppers.

In plant breeding efforts have been directed largely to the production of disease resistant varieties, disease playing an increasingly important part in limiting crop production. Rust in wheat still baffles the investigators, and, worse still, new diseases brought into the different countries sometimes spread with considerable rapidity and do much damage before resistant varieties can be found. The problem of immunity has been much studied but no satisfactory explanation is yet found, while the cause of the virus diseases remains as elusive as ever. In Canada a search is continually being made for new varieties of wheat with short growing periods more suitable to the short seasons of the northern parts. There has been a steady pushing up of the northern boundary of the wheat growing area, and no one now would venture to set definite limits to it. In crop production the most striking development has been the manufacture of synthetic nitrogen fertilizers, which is now so firmly established along broad lines as finally to remove the fear of world starvation expressed in Sir W. Crook's famous address to the British Association in 1898.

In animal husbandry there have been steady developments in the prevention of animal disease, the subject now being regarded as in a great part a matter of hygiene and nutrition. The discovery of vitamins is opening up new fields of nutrition in relation to growth and health of men and animals. Great attention has been paid to the mineral nutrients, lack of which has been found responsible for serious diseases in Africa and elsewhere. Deficiency of phosphorus is one of the most serious, but deficiency of calcium and possibly of iodine is also responsible for animal disease. Fortunately, the remedy can be found as soon as the causes can be diagnosed. Considerable progress has been made in the treatment of diseases by various sera. In dairying, great strides have been made in the production of clean milk.

In every country in the civilized world the economic situation in agriculture has been profoundly altered by the great advances made in our knowledge of the effect of temperature on agricultural produce. Research laboratories have been set up particularly for studying the effects of low temperatures, and refrigeration is steadily being reduced to an exact science. In the United States, particularly in the U.S. Department of Agriculture and the State Experiment Stations, much attention is now being given to economic and sociological research in reference to agriculture and rural life.

(E. J. R.)

AGRICULTURAL REVOLUTION, THE, a term indicating that period in history which witnessed the transition of English methods of farming from mediaeval to modern conditions. During the 18th century increasing knowledge and new inventions revolutionized both agriculture and stockbreeding. At the same

time the rapid growth of enclosures vastly improved the conditions under which farming was carried on. But it increased the resources of the great landowner to the extinction of the yeoman farmer, and thus an essentially progressive movement in agriculture brought much misery in its train. The expenses incurred by the enclosure movement, the subsequent rise in the value of land, reductions in agricultural establishments, the protective system of the corn laws, and the supplementing of wages from the rates (Speenhamland system [*q.v.*] 1795) raised prices, lowered wages and depressed a large section of the agricultural population to the level of paupers. (*Cf. INDUSTRIAL REVOLUTION.*) See also AGRICULTURE; COMMONS; CORN LAWS.

AGRICULTURAL SOCIETIES AND SHOWS. In British agricultural history there is no parallel to the enthusiasm which spread through the country during the last quarter of the 18th century. It spread downwards from George III., "Farmer George," who himself contributed to Young's monthly publication, *Annals of Agriculture*, started in 1784. The politicians, including Fox and Burke, the great landowners, such as the duke of Bedford and "Coke of Norfolk," all shared in the zeal and were excited by farming topics and busy with farming experiments. One of the results was the founding of the Board of Agriculture by Pitt in 1793. But the board was preceded by the birth of a number of local associations in different parts of the country. Among the earliest and more important were the Bath and West of England Society, founded in 1777; the Highland Society in 1784, and the Smithfield Club in 1798; and before the end of the century very many of the counties had founded organizations of one sort or another for the promotion of the art and craft of agriculture.

The chief activity of the greater societies was the holding of an annual agricultural show; and the annals of many such shows begin in the year of the society's foundation. But in this respect the board did not at once follow the example of the societies, and its popularity waned as agriculture became depressed. It was indeed dissolved in 1822, but in the year before its temporary extinction it held, at Aldridge's repository, the first national agricultural show. It was modelled on the many local shows, of which the oldest had already a history of 44 years. But the agricultural show, such as we know it to-day, may be dated from the formation of the Royal Agricultural Society at a later date.

The Royal Agricultural Society.—This society was founded in 1838 and received its charter in 1840, the year from which most critics date the rise of modern scientific farming, as fostered by the researches of Liebig and his British successors Gilbert and Lawes. The first show under its auspices was held at Oxford under the presidency of Lord Spencer. It was various in range and of considerable extent, though small in comparison with the shows of to-day. There were six classes only for cattle, three for sheep, one for horses, and one for pigs. The section for implements was considerable, and prizes were also given for essays on agricultural subjects, for skill in ploughing, and for the best farm in Oxfordshire. Since that day the scope of this show, as that of most others, has increased; and its form has been closely imitated in the British empire overseas and in foreign countries. Few contrasts in Britain surprise foreign visitors more than the magnitude and excellence of its agricultural shows, which are celebrated in a country that is regarded as overwhelmingly industrial, and are indeed superior to any in the world.

The great additions to the scope of agricultural shows in the 20th century were made, not only with the idea of promoting agricultural science, but also to increase the spectacular attractions, and so provide funds for the proper objects of the society. The modern royal show, which continues for five days, may occupy as much as 100 acres of land, and the machinery, much of it seen "in motion," is alone a great feature. Besides classes for almost all breeds of stock and of poultry, and in addition to forestry, educational and scientific sections, it contains pavilions or tents for the display of rural crafts, and for the work of the women's institutes. A flower show, usually both large and elaborate, is housed in a series of great marquees. A working dairy is seen in action several times a day. Lectures and demonstrations of many sorts are given at intervals, and every afternoon, except on the

opening day when the bulk of the judging is done, horse jumping and harness competitions are held in a spacious ring and draw large crowds.

The royal show has always been peripatetic, except for the years 1903, 1904, 1905, when it was brought to Park Royal, on the north of London, with disastrous results to its finances. The prevailing principle in the selection of sites is to visit populous districts more or less alternately with purely agricultural centres; and except when the weather has been unfavourable, it has generally been found that the money made at the crowded centres enables the society to bear the losses sustained in more strictly agricultural areas.

Several local shows are comparable with the royal, though rather smaller and of shorter duration. But similar variety of exhibit is seen in the shows of the Highland Society, of the Bath and West of England, the Welsh national show, the "Royal Counties," the "Three Counties" and indeed many of the larger county shows, notably in Lancashire, Yorkshire, Cornwall, Oxford, and Suffolk. Many of these, as well as the royal, attract large numbers of foreign buyers, especially from South America.

The history of most of these shows and societies was a history of progress, with some oscillations, till the years of depression in agriculture following the great prosperity of 1918 and 1919. It began to appear at this time that the shows were too many, and perhaps too elaborate. Though many societies remained abundantly prosperous—and such shows as those of the Suffolk, Lincolnshire, and Cornish societies were never better than in 1927, the year of the 150th anniversary of the earliest, a movement for the amalgamation of local and county shows now began as a result of the unsatisfactory agricultural conditions and a shrinking of many farmers and landowners from the expense of exhibiting. Though some contraction may be inevitable, yet the breed societies, more in Britain than in other countries, show no sign of degeneration, and are the backbone of the agricultural show. Elsewhere two of the largest agricultural shows in the world are held annually at Buenos Aires and in Sydney, New South Wales. Both have a generic likeness to the English shows and enjoy the same popularity.

Although as already recounted, the Royal Agricultural Society of England was nearly ruined by the experiment of holding its show in London, the great fat-stock shows, held in November and December, and the dairy show, held in London in October, have flourished progressively under urban conditions. Especially since dairying took the lead over corn-growing as the chief department of British farming following the World War, the annual dairy show has become a remarkable epitome of the science of dairying as of the quality of the dairy breeds of cattle. Of the winter fat stock shows the three that attract the best fat stock are held at Norwich, Birmingham, and the Agricultural Hall at Islington in North London. The Smithfield Club, which is responsible for the London show, was founded as the Smithfield Cattle and Sheep Society as early as 1798, and has always emphasized at its shows its original object to promote the supply and breeding of the best meat.

(W. B. T.)

IN THE UNITED STATES

Agricultural Societies.—Educational advancement in agriculture has been marked by undertakings common to many localities. Agricultural societies came into being in the late 18th and early 19th centuries. The New York Society for the promotion of useful arts, though not confined to agriculture, was founded in 1766. The New Jersey society for promoting agriculture, commerce and arts was in existence in 1781. The Philadelphia society for promoting agriculture was established in 1785. In the following years the number of local, county and State agricultural societies increased rapidly and played an important part in initiating systematic instruction in agriculture. In 1792 the New York society published a volume of its transactions, and the Massachusetts society issued bulletins on agricultural topics. The holding of fairs in Cambridge was suggested to the Massachusetts society in 1801. In 1807, Elkanah Watson exhibited two merino sheep in the public square of Pittsfield, Massachusetts. This may well

mark the beginning of cattle shows. enterprises of no mean educational value.

The South Carolina agricultural society, organized in 1785, bought, in that year, a tract of land on which experiments were to be conducted. In 1792 the New York agricultural society provided funds to the trustees of Columbia college for the endowment of a professorship in natural history, chemistry and agriculture. The Philadelphia society received, in 1794, recommendations from one of its committees that the legislature of the State be requested to support agricultural education in schools and colleges. A grant of \$500 was made by the Massachusetts society in 1801 for the establishment of a professorship of natural history at Harvard college.

The Columbian agricultural society was founded at Washington in 1809. It was the forerunner of the U.S. Agricultural society, organized in 1852 at a convention of delegates from 12 State agricultural societies. During 1817-25 the allotment of State funds to county and local societies encouraged their extension. In 1819, State aid was provided in New York and Massachusetts. The latter State offered \$200 annually to every society raising and investing a fund of \$1,000. For larger investments the subventions reached a maximum of \$600. In the same year the legislature of New York appropriated \$10,000 a year for four years "for the promotion of agriculture and family domestic manufactures." The climax of rural organization was reached in 1820-25. Most of the country agricultural societies disintegrated in the following 25 years, largely as a result of the withdrawal of State aid. On the other hand, the State agricultural societies continued to flourish. By means of meetings, conventions, farmers' institutes, fairs, exhibits, demonstrations, bulletins and reports they exerted a profound influence on farm practices and served as important educational agencies. Later, many of them became State boards of agriculture and, later still, State departments of agriculture. As a national group they have developed common policies that directly affect educational and regulatory activities in the several States. (X.)

Agricultural Shows.—Fairs and exhibitions have been an integral part of American country life for more than a century and have played an important part in the progress of agriculture. In the early colonial days it was the practice of the farmers at the close of the harvest season to take their farm products and fattened live stock to the village and display them there on the commons, primarily for sale or trade; but often such exhibitions were also motivated by a sense of pride and a desire to show the neighbours what had been accomplished in the way of producing a particularly fine specimen of animal or farm product. These occasions naturally developed into gala days for the community because of the opportunity they afforded rural people from widely separated districts to meet for recreation and social contact, and because the finish of the harvest found the people in a festival mood. From post-harvest sales and gala days of early times it was a natural step to the fair as it is known to-day, with its exhibits of fruits, vegetables, grain and live stock competing for prizes and ribbons, and the horse races, ball games, fireworks and other amusement features added to help carry the expense of the event.

The first permanent fair association in the United States grew out of a cattle show inaugurated in Pittsfield, Mass., in 1810. By 1860 the agricultural fair was an established institution, practically every State and county of agricultural importance holding an exhibition in the autumn after harvest. Then came a time, about 1900, when amusement features, such as horse racing, outweighed the agricultural exhibits in importance, and the time of holding the fairs was determined more by the convenience of the racing circuit than by the agricultural factors. Fairs as agricultural institutions suffered and many counties abandoned them. More recently, however, there has been a revival of the business of exhibiting agricultural products, and the county fair is once more assuming its original object. State fairs are now permanently established and in general well-managed and prosperous institutions, giving sufficient attention alike to education, recreation and entertainment features to insure a well-balanced programme

and continued success. To-day there are county fairs, district fairs, State fairs, regional fairs including two or more States and national and international expositions of world-wide fame.

The first great show of more than local importance, known as the American Fat-Stock show, was established in 1878 by the Illinois State board of agriculture and was held annually in Chicago from that time until 1897. It was the outgrowth of the desire of a number of cattle breeders and feeders, as well as men interested in horses and swine, to stage a show in keeping with the progress of the purebred live stock industry. The show was patterned after the famous Smithfield Club show in England and flourished for many years until political influence and inadequate support caused its failure in 1897. Three years later, the present International Live Stock Exposition was organized. It held its first show in Dec. 1900, at the Union Stock Yards in Chicago. It was founded largely through the efforts of a group of admirers of purebred animals which included such famous live stock men as Robert B. Ogilvie, Mortimer Levering, William E. Skinner, Alvin H. Sanders, John Clay and John Spoor. Profiting by the experience of the old Fat-Stock show, the new organization laid plans for a great educational institution free from political favoritism. Following closely the ideals of the founders, succeeding directors have made the International the leading exponent of a great movement for the improvement of live stock and crops in America. The International has been held annually in Chicago ever since its organization, except in 1914 and 1915, when it was omitted on account of the presence of foot-and-mouth disease in the United States. Staged usually during the last week in November and the first few days in December, a time when all other fairs and shows have been completed, the International draws the year's prize-winning draft horses, beef-cattle, swine, grain and hay exhibits and numerous other farm products from all over the United States and Canada. The organization owns its own grounds, covering 500 paved acres. Joined to the many barns and other buildings housing the show stock is the amphitheatre, seating 5,000 visitors and enclosing a tan-bark arena 600ft. long. Here the finest live stock in America have paraded annually for a quarter of a century before the eyes of leading judges of North and South America and Great Britain. Standards have been set by this show. Year by year this institution has continued to expand until every phase of American agriculture is now embraced within its scope. While the display of breeding and fat live stock is still the cornerstone of the exposition, many educational and entertainment features have been added from time to time. The evening horse shows, including ponies, hunters and jumpers, saddle and light harness horses, have won world fame for the quality of the entries. The various State colleges have long been exhibitors of some of the finest live stock in all classes and the annual live stock judging contest for agricultural college students is of far-reaching importance as an educational feature. Within the last decade 1,000 or more farm boys and girls have attended the International annually as a reward for achievement in club-work in agriculture and homemaking. Classes for baby beeves raised and fitted for show by these young farmers have formed one of the new and important attractions, and the live stock judging contest, open to champion junior judging teams from every State, is another innovation. Interest in feeding, fitting and showing live stock is encouraged by a large class of awards for herdsmen, caretakers and other helpers.

While the International is the live stock classic of the year, there are other shows of great importance to the regions in which they are held. The exhibits at such shows are often on a par with those at the International, although they draw from a much more limited territory. Such shows as the American Royal Live Stock Show held annually at Kansas City, Mo., the Pacific International Live Stock Exposition at Portland, Ore., the Southwest Exposition and Fat Stock show at Ft. Worth, Tex., and the National Western Stock show at Denver, Colo., are important shows held prior to the International. From these it draws many of the winning animals. The great show of the East is the Eastern States Exposition held annually at Springfield, Mass., since its organization in 1916. Dairy cattle are the big feature of this show, although

there are always excellent classes of all breeds of beef-cattle, sheep, swine, light horses, hunters, jumpers and ponies.

The National Dairy Show is primarily a show for the advancement of the dairy industry, although some classes are held for horses. Its live stock exhibit consists of 1,000 or more of the finest dairy cattle of all breeds in America. It is by no means limited to the live stock end of the industry. Machinery and equipment for the creamery, the distributing plant and every other phase of dairy manufacture, form a large part of the attraction and add to the educational value of the show. The show was first held in 1906 in the Chicago Coliseum. The success of this first venture resulted in the organization of the National Dairy Association and the continued success of the show ever since. It is a much travelled show, having been held in Chicago, Ill.; Columbus, O.; Springfield, Mass.; Milwaukee, Wis.; Detroit, Mich.; Indianapolis, Ind.; St. Paul, Minn. and Memphis, Tenn. Another important dairy show is the Dairy Cattle Congress held annually at Waterloo, Ia. The National Swine Show is the leading show in the world of breeding swine and is devoted exclusively to this branch of the live stock industry. While in point of numbers it is often exceeded by some of the larger State fairs, no other swine show draws so many champions of the various breeds from all parts of the continent. It was organized by the National Swine Growers' Association primarily as a breed-promotion institution, holding its first show in 1916 at Omaha, Neb. It has also travelled, having at different times been held in Cedar Rapids, Ia., and Des Moines, Ia. In 1921 it moved to Peoria, Ill., where the association now owns its buildings and grounds.

Poultry shows have been held in the United States for more than 50 years. Thousands of shows of varying sizes are held annually, small towns and communities having their local shows and many State fairs having poultry exhibits also. Large State shows are held later in the season and are followed by regional or international shows. The leading poultry show is the Madison Square Garden Poultry Show at New York city, where it has been a regular event since 1870. Thousands of birds are exhibited in individual cages designed to show them to advantage. Pigeons, bantams, and every other variety and breed of feathered domestic fowl are included. The Boston Show was the first large poultry show in the United States, having been started in 1865. It is well balanced and in some respects is better than the Madison Square Garden show. Other poultry shows of nation wide interest are held in Chicago and Kansas City.

There is scarcely a branch of the agricultural industry that does not have some show of more or less national scope. Special shows are held by rabbit breeders and fanciers, by kennel clubs and by organizations interested in bees and in song birds. There are shows exclusively for horses of certain breeds, for fruits and vegetables and for flowers. The Society of American Florists and Ornamental Horticulturists holds the National Flower Show at a different place each year. The International Flower Show is held annually in the Grand Central Palace, New York city. The American Orchid Society holds a large show, usually every other year, at Madison Square Garden. Countless other flower societies exhibit their new products in various local and regional shows. Obviously all these exhibits are of immense value to specialists as well as amateur breeders and growers in making progress in their profession.

Canada.—Approximately 500 fairs are held annually in Canada, most of them provincial or local. The most important is the Canadian National Exhibition at Toronto, Ont. Held usually in September, this show includes exhibits from practically every branch of agriculture and allied industries and emphasizes educational features. Of the 2,368 fairs held in 1927 in North America, with a total attendance of 39,468,000, none exceeded the Canadian National with its 1,870,000 visitors. No other North American fair owns buildings and grounds of greater value; its valuation is \$13,500,000, while that of its nearest competitor, the Ohio State Fair at Columbus, O., is \$5,000,000.

Another fair of note is the Royal Agricultural Winter Fair, patterned after the Royal Agricultural Show in England. It was first held in 1922 in the new coliseum on the grounds of the

Canadian National and has since grown rapidly. It is held annually in Toronto, usually in December, and limits its exhibits to live stock, grain and hay and other farm products. It draws its entries from the best herds and flocks and fields of Canada, the United States and other countries. Dominion honours for live stock are awarded here.

Other agricultural fairs of note are the Central Canada Exhibition, held annually at Ottawa, Ont.; the Calgary Exhibition and Stampede at Calgary, Alta.; the Old Winter Fair at Guelph, Ont.; the Provincial Exhibition, New Westminster, B.C.; the Quebec Provincial Exposition, Quebec, P.Q.; the Provincial Exhibition, Regina, Sask.; and the Great Eastern Exhibition, Sherbrooke, Province of Quebec.

South America holds many local or regional fairs and expositions every autumn, but the principal one is the Argentinian *Exposición Nacional de Ganadería*, usually called the Palermo show. This exposition ranks with the leading live stock shows of the world. It was inaugurated in 1875, with but 18 head of horned cattle by the Argentine Rural society (founded in 1866). Its early progress was irregular and in some years no shows were held because of financial and other difficulties. With the growth of the live stock industry in Argentina and other South American countries it finally became established and is now held annually in the autumn at Buenos Aires, where the society owns grounds and buildings near the fashionable Palermo suburb. The Palermo show is principally a beef-cattle show. There are often from 1,000 to 1,800 head of Shorthorn bulls in the show rings. The Shorthorn classification is perhaps the most elaborate show-ring exhibit to be found in any live stock show in the world, there being as many as 29 classes, in which the animals range from junior yearlings to 3-year-olds. The great number of classes is due to the separation of the animals into groups differing in age by from 15 to 30 days, whereas in other countries most show classes are from 4 to 8 months apart in age. Another unique feature is the compulsory auction of practically all animals exhibited, the purchaser paying a selling commission of 6%. The commission rate is doubled if the owner buys back his own exhibit. The auctioning of the grand champion bull is the outstanding attraction and has become an event in the social season. A week or ten days is often required to complete the auction after the closing of the show. Besides shorthorns, other breeds are shown in great numbers and in good quality, as are horses of both light and draft breeds, sheep, swine, poultry and other agricultural exhibits. Dairy cattle are also an important feature of interest. The exhibition grounds are beautiful and in perfect condition and the buildings are elaborately designed and well arranged around the show rings to permit all judging to be done in the open.

Two other important live stock shows in South America, both of which are held in Uruguay, are the National Live Stock and Poultry Exposition at Montevideo, and the Live Stock and Poultry Exposition at Salto. The exposition at Montevideo is under the management of the Rural Society of Uruguay and is largely a cattle show, but there are usually good classes of sheep, swine, dairy cattle and horses. The Salto show is principally a cattle show, the Hereford breed predominating. Many ranchmen from southern Brazil go to this show to buy their breeding stock.

(L. S. R.)

AGRICULTURAL STATISTICS. The collection of statistics relating to the use and output of agricultural land is a comparatively modern institution. It is only within the last half century that the duty of a government to obtain such information has been generally recognized. During that period, thanks largely to the influence of the International Statistical Institute, and of the International Agricultural Institute, the systematic collection of agricultural statistics has been undertaken in most countries, although there are still some which lag behind.

In England it might be claimed that the first agricultural statistics were those collected in the 11th century in Domesday Book, which included a record of the use of all land then under cultivation. But it was not until the 19th century that the State undertook, as an ordinary function of administration, the annual collection of statistical information about agriculture. Attempts

were previously made by private enterprise to ascertain facts, the most famous being that of Gregory King in 1688. He estimated the total area of England and Wales at 39,000,000 acres, which proved to be somewhat exaggerated when actual measurements became available. He further estimated the area of arable land at 9,000,000 acres, of pastures and meadows at 12,000,000 acres. In 1827 another estimate was submitted to a select committee of the House of Commons by W. Couling, who based his calculations on personal investigations made between 1796 and 1816, and again in 1824-27, in the course of which he claimed to have travelled 50,000 miles. His estimates covered the whole of the British Isles, in which he reckoned there were 19,000,000 acres of arable land and 27,000,000 acres of pasture and meadow. In England and Wales he estimated the arable area at 11,000,000 acres and pasture and meadow at 17,000,000 acres. Spasmodic attempts were made from time to time in different parts of the country to collect agricultural statistics. In 1831 the magistrates of Norfolk instituted an enquiry for that county, and a little later the Board of Trade endeavoured to obtain, experimentally, particulars of the agriculture of Bedfordshire. In 1854 the Highland and Agricultural Society of Scotland established a system of agricultural statistics for Scotland, the cost being borne by the Government. This continued for three years; it was discontinued then in consequence of the withdrawal by the Treasury of financial support. In 1855 a committee of the House of Lords reported in favour of uniform and compulsory returns and in 1864 a resolution was passed by the House of Commons demanding the immediate establishment of a national system of agricultural statistics. No legislation was passed but the Board of Trade gave effect to the wish of Parliament and established a system of annual returns from every occupier of agricultural land of the acreage of crops and number of live stock on each holding. The returns were first obtained in 1866, and in 1884 they were supplemented by the collection of estimates of the year's yield of the principal crops. The responsibility for the collection of all agricultural statistics was transferred from the Board of Trade to the Board of Agriculture soon after its establishment in 1889.

The most systematic attempt to provide agricultural statistics by private enterprise was that made by Lawes and Gilbert in their calculations of the production and consumption of wheat in the British Isles. These were started in 1852 and continued annually until official estimates of the yield of wheat and other crops were begun 32 years later. The method they adopted was to ascertain the average yield per acre of five experimental plots at Rothamsted on which wheat was (and is) grown continuously year after year. Each of the plots was very differently manured and one was always unmanured. The yields, of course, varied widely and it was assumed that these variations would on the whole represent the differences in the produce of crops grown under widely differing conditions throughout the country. In the absence of any satisfactory system these estimates were generally accepted as fairly trustworthy for a series of years, and for comparing the results of one harvest with another.

Systems of Collection.—Much discussion has taken place among statisticians and economists as to the best system of collecting agricultural statistics. In practice the question is settled in most countries mainly on administrative and financial grounds without much regard to a theoretical ideal. For ascertaining the area of every agricultural holding and of the crops grown thereon, and for enumerating the farm live stock the distribution to every occupier of a schedule, analogous to a census schedule, is generally agreed to be desirable. This was the system adopted for the British Isles in 1866, and is still in force, although the schedule of enquiry has been gradually made more elaborate and comprehensive. The schedules are distributed by post through the local crop reporters who are also responsible for their collection. The returns are made on June 4 in each year. In some countries, where a similar system is adopted, the returns are collected at longer intervals. In Denmark, for example, the enquiry is made quinquennially and in the United States decennially, annual variations being estimated. Returns of the yield of crops are obtained

by other methods. In England and Wales the Ministry of Agriculture has a staff of 320 specially appointed crop reporters, each of whom is responsible for estimating the average yield of crops in every parish of his district. In Belgium the administration of each commune is responsible for obtaining estimates of produce. In France the duty is also placed upon the communal authorities, who call into consultation a limited number of representative farmers. Similar systems are adopted in other continental countries.

Statistics of World Agriculture.—The total land area of the world, omitting the Polar regions as unsuited for agriculture, is 50 million square miles. Of the four continents, Asia and America are almost equal in extent and together comprise 63% of the total area. Africa comes next with 23%, and Europe has less than 8%, the remainder being scattered in "Oceania" which accounts for 6½% of the total surface. Statistics of agriculture are only partially available for this vast area, although they are gradually becoming more comprehensive. The alteration of territorial boundaries, and the establishment of new States, which followed the World War, have necessarily involved the re-adjustment of administrative arrangements in Europe for the collection of agricultural statistics, and disturbed the sequence of comparative figures. But the International Agricultural Institute obtains returns for all the principal European countries on more or less uniform lines as well as for North America, Argentina, Chile, India, Australia and New Zealand. Returns for Russia, after a prolonged period of uncertainty, are again becoming available but are not yet included in the general summaries issued by the institute. Taking the area of land under arable cultivation as representing the area of crop-production, India has about one-third of the total, the United States coming next with 28%, which is nearly equal to the whole arable area of Europe, excluding Russia.

The average production of the chief cereal crops in those countries for which returns are available is returned as follows, the figures representing millions of bushels:—

	Wheat.	Rye.	Barley.	Oats.
Europe	1,179	766	592	1,494
Canada, U.S.A. and Mexico	1,180	89	269	1,828
Asia	387	..	129	..
Africa	99	..	93	23
Argentina	204	3	10	59
Australia	129
	3,187	858	1,093	3,404

Maize, for which returns are available for ten European countries, the United States, Canada and Africa, has a greater production than any other cereal crop except oats, the total being returned as 3,352 million bushels. The potato crop, although less widely grown than wheat, exceeds it in total production, the returns accounting for an average of 4,343 million bushels.

Statistics of farm live stock are less complete than those of crops and are in many countries collected infrequently at irregular intervals. The following table shows approximately the world's totals of each kind of animal and their relation to the human population and to area:—

	Number.	Per 1,000 inhabitants.	Per 1,000 hectares.
	<i>Millions.</i>	<i>Head.</i>	<i>Head.</i>
Horses	99·8	58·7	9·4
Cattle	510·9	295·7	46·2
Sheep	532·2	325·9	49·3
Goats	116·8	114·9	14·0
Pigs	209·7	155·9	19·6

Unfortunately no statistics of any reliability are available for China (pre-eminently an agricultural country). The annual value of pigs reared in China must be enormous and cattle and horses are everywhere in evidence; but the unsettled state of the country since the Revolution has made records difficult to obtain.

The distribution of the animals and their relative importance as indicated by their density are shown in the following table:—

	No. per 1,000 hectares.				
	Horses.	Cattle.	Sheep.	Goats.	Pigs.
Europe	39.3	124.0	155.7	27.4	64.3
North & Central America	11.1	38.8	19.6	4.4	28.5
S. America	10.1	41.6	45.8	8.9	12.6
Asia	4.7	53.3	29.7	23.3	19.4
Africa	0.9	16.5	34.4	14.9	1.4
Oceania	3.3	18.8	116.4	0.3	1.3

(A precise date for the statistics of the foregoing three tables cannot be given; they represent an average for a series of recent years, a ten-year average being aimed at up to 1928.)

The International Agricultural Institute has formulated a scheme for a world agricultural census in 1930 in which it is hoped all the chief countries will co-operate. If this can be generally carried out on uniform and systematic lines, statistics of the world's agriculture will be more complete.

Statistics of British Agriculture.—The continuity and in some degree the comparability of agricultural statistics for the British Isles have been affected by political and administrative changes. For many years they were collected by the Board of Agriculture for Great Britain and by the Department of Agriculture for Ireland. In 1912 the Board of Agriculture for Scotland was established and took over the collection of statistics in that country. When Ireland was divided separate agricultural departments were set up for Northern Ireland and the Irish Free State respectively, so that there are now four departments responsible for the agricultural statistics of the British Isles.

The total area of land under crops or grass (in other words the "farmed" area) in Great Britain is nearly 30½ million acres, of which 13¼ millions are under arable cultivation and a little over 16½ millions in permanent pasture. The acreage of each of the chief crops in 1926 was as follows:—

	<i>Acres</i>
Wheat	1,646,000
Barley	1,270,000
Oats	2,804,000
Beans	218,000
Peas	120,000
Potatoes	641,000
Turnips and swedes	1,158,000
Mangold	340,000
Clover and rotation grasses	3,987,000
Small fruit	77,000
Hops	26,000
Sugar beet	229,000

The number of farm live stock in Great Britain in 1926 was as follows:—

	<i>No.</i>
Horses	1,307,491
Cows and heifers	3,206,732
Other cattle	4,244,181
Total cattle	7,450,913
Breeding ewes	9,870,107
Other sheep	14,191,712
Total sheep	24,061,819
Pigs	2,345,431

The average total production and yield per acre in the ten years 1916–25 of those crops for which estimates are obtained annually are shown in the following table:—

	Total produce.	Yield per acre.
	<i>Tons.</i>	<i>Cwt.</i>
Wheat	1,717,000	17.3
Barley	1,185,000	15.0
Oats	2,230,000	13.8
Beans	187,000	15.7
Peas	75,000	13.7
Potatoes	4,133,000	6.2
Turnips and swedes	18,009,000	13.7
Mangolds	7,472,000	19.1
Hay:—		<i>Cwt.</i>
Clover and rotation grasses	3,032,000	29.1
Permanent grass	4,905,000	21.4

Particulars of other crops, and statistics relating to agricultural output which are not included in the annual returns are obtained from time to time in connection with the census of production (see AGRICULTURE, CENSUS OF).

(R. H. R.)

AGRICULTURAL WAGES. The origin of wages in agriculture was the disappearance of the serf. So long as slave labour was available no question of remuneration arose. In England serfdom, speaking generally, was a product of the Norman Conquest, when the organization was established on a system of "villeinage." (See VILLENAGE and MANOR.) The gradual emancipation of the villeins and their development into tenant farmers was accompanied by the emergence of a class of men who occupied no land, or not sufficient for subsistence, and were therefore compelled to seek a living by selling their labour to others.

In the middle of the 14th century the relations of employers and employed were violently changed by the catastrophe of the Black Death, or plague. In the rural districts large areas were left derelict by the death of the occupiers and the owners were unable to keep them in cultivation for lack of labour. An urgent demand for labour followed, and wages rose suddenly in consequence of the restricted supply.

State Regulation.—In these circumstances the State, first by Royal Proclamation and subsequently by statute, intervened. The famous Statute of Labourers enacted that "Every man or woman, of whatsoever condition, free or bound, able in body, and within the age of three score years . . . and not having of his own whereof he may live, nor land of his own about the tillage of which he may occupy himself, and not serving any other, shall be bound to serve the employer who shall require him to do so, and shall take only the wages which were accustomed to be taken in the neighbourhood where he is bound to serve." The "accustomed" wages were those paid in the year before the plague appeared. Those who attempted to get higher wages were liable to imprisonment, while those who either paid or received more than the authorized wages were fined three times the amount of the excess. Justices were sworn to enforce the Act and to fix the actual rates of wages in each district. (See LABOUR LEGISLATION.)

The Statute of Labourers was frequently amended and its provisions and penalties made more stringent, but nevertheless it is evident that it failed to prevent a substantial rise in the agricultural wages. Thorold Rogers in *Six Centuries of Work and Wages* declares that the 15th century and the first quarter of the 16th were "the golden age of the English labourer if we are to interpret the wages which he earned by the cost of the necessities of life. At no time were wages, relatively speaking, so high, and at no time was food so cheap." Attempts were constantly made to reduce wages by enforcing the Statute of Labourers, but ineffectively. Wages kept at a high level, gradually became customary and were ultimately recognized, tacitly if not explicitly, by parliament.

Under the vigorous rule which followed the accession of Elizabeth more effective measures were taken to regulate wages. The Justices in Quarter Sessions were empowered to fix rates of wages in husbandry and they exercised their powers assiduously and rigorously. Thereafter wages conformed to the assessments of Quarter Sessions and were reduced notwithstanding the continual increase of the cost of living. The establishment of a system of Poor Law Relief tended to depress the level of wages. Magistrates were encouraged to reduce wages knowing that if the wage-earner became destitute the responsibility for his maintenance would be a charge on the whole community while farmers, and ultimately landowners, would benefit by the lowness of the wage.

At the end of the 18th century a momentous step was taken which had the effect of still further depressing the level of agricultural wages and completing the pauperisation of the wage-earners. It affords a curious instance of the perversion of good intentions by misguided policy. At the Berkshire quarter sessions in April, 1795 the chairman, Mr. Charles Dundas, M.P., afterwards Lord Amesbury, expatiated on the necessity of increasing the wages of agricultural labourers instead of leaving them to apply for poor relief for the support of their families, which was impossible on a wage of one shilling a day. It was resolved to

convene a meeting to consider the question. The notice of the meeting referred to "the great inequality of labourers' wages and the insufficiency of the same for the necessary support of an industrious man and his family," and proposed that the meeting should "limit, direct and appoint the wages of day labourers." The meeting was duly held and at the outset unanimously agreed that "the present state of the poor does require further assistance than has been generally given them." A proposal to enforce the payment of wages in proportion to the price of bread (in other words the institution of a minimum wage) was discussed and rejected, but it was resolved "very earnestly to recommend" to farmers that they should "increase the pay of their labourers in proportion to the present price of provisions." The magistrates attending the meeting pledged themselves, each in his district, to ensure that every "poor and industrious man" should have either from wages or from the poor rates 3s. weekly when the gallon loaf cost 1s. and for his wife and each child 1s. 6d. The man received 3d. and each of his family 1d. more or less for every penny that the price of the loaf rose or fell. (See ASSIZE.)

This system and scale were generally adopted throughout the country, the only two counties in which it did not, sooner or later, come into operation being Durham and Northumberland. The effect was as might have been foreseen. Farmers so far from adopting the earnest recommendation of the Speenhamland magistrates tended more and more to reduce wages and to throw the balance required for subsistence on the rates. There were local differences, arising from various causes, and in 1824 a House of Commons Committee on Agricultural Wages reported that whereas in the northern counties, which the Speenhamland system had not reached, wages were from 12s. to 15s. per week, in other counties they varied from 8s. or 9s. to 3s. for a single man and 4s. 6d. for a married man.

In 1830 there was a serious revolt of agricultural labourers originating, as others had done, in Kent but rapidly spreading to Sussex, Surrey, Berkshire, Hampshire and Wiltshire. There is no doubt that it arose from a feeling of general desperation. Among the immediate causes were the brutality of the game laws, the introduction of threshing machines, and the ruthless administration of poor relief by parish officers, but the lowness of wages was the general grievance which united all. The demand put forward was for a wage of 2s. 6d. per day. The rising was suppressed, not without bloodshed, and the punishments which followed were based on the theory, then commonly accepted, that extreme severity was the only deterrent to crime. When in 1835 the old Poor Law system and the anomalies and abuses with which it was encrusted were abolished, State regulation of agricultural wages was abandoned, having existed in various forms for nearly 500 years.

Wages Machinery.—After about 80 years of *laissez faire* the State in 1917 again intervened to regulate the wages of agricultural labourers. In doing so it adopted a new principle, the object in view being to secure that wages did not fall below a fair level. This policy was embodied in the Corn Production Act, 1917, which was passed to stimulate the production of food and to authorize the compulsory cultivation of land. Prior to 1917, with the exception of a few areas where trade unions had successfully overcome the inherent difficulties of organizing agricultural workers, no system of collective bargaining existed for the fixing of agricultural wages. When, under the Corn Production Act, 1917, farmers were given a State guarantee for corn prices there was coupled with it a system of wage-fixing machinery for agriculture on the lines of the Trade Boards already in operation for several other industries, and the first Agricultural Wages Board was established, together with County Wages Committees.

The Corn Production act was a war measure, its duration being limited to six years. But after the war the Government re-enacted its main provisions in the Agriculture act 1920, which embodied what was heralded as a permanent agricultural policy. The wage-fixing machinery was continued in the same form, *i.e.*, an agricultural wages board, with local committees, entrusted with absolute power to settle minimum rates of wages. This act was repealed in the following year and the Agricultural Wages Board

was abolished. The Corn Production (Repeal) act 1921 set up local conciliation committees charged with the duty of agreeing upon minimum wages for their districts but without the power of enforcing their decisions. Three years later however the legally enforceable minimum wage was re-established by the Agricultural Wages (Regulation) act 1924. This set up, in form, the same wage-fixing machinery as before, but with the important difference that the responsibility for fixing rates was placed on the district committees, the Central Wages Board merely embodying their decisions in statutory form. The enforcement of the orders was entrusted to the Ministry of Agriculture, instead of to the wages board as under the acts of 1917 and 1920.

Under this Act England and Wales are divided into areas on a county basis, each having an autonomous Agricultural Wages Committee composed of equal numbers of representatives of employers (nominated by the National Farmers' Union), and workers (nominated by the National Union of Agricultural Workers and the Workers' Union), together with two impartial members appointed by the Minister of Agriculture and an outside chairman selected by the committee itself. The Central Agricultural Wages Board is similarly composed of equal numbers of members representing the organisations of employers and workers, together with a panel of five independent members (including the chairman), appointed by the Minister of Agriculture.

Rates of Wages.—By the Corn Production act the Agricultural Wages Board was given discretion to fix minimum rates of wages, subject to the proviso that no amount less than 25s. per week for able-bodied men should be fixed. This limitation, in fact, never became operative. When the Agricultural Wages Board began operations in 1918 current rates of wages everywhere were higher than that figure. Under the act the board could not fix a minimum wage until it had received and considered a recommendation from the district committee concerned. The Norfolk committee sent up the first recommendation which was to fix 30s. This was adopted by the board, and subsequently the average for the whole of England and Wales worked out at 30s. 6d. There were four subsequent revisions of the rates, in May 1919 when the average was 37s. 10d., in April 1920, 43s., in August 1920, 46s. 10d., and in Sept. 1921, 42s. 3d.

During this period prices of commodities including farm products were abnormally high, but in 1921 they began to fall rapidly, a fact which was recognized by the Agricultural Wages Board in the reduction by over 4s. of the minimum wage just before its abolition. Under the Conciliation Committee system the reduction proceeded rapidly and in less than a year the average had fallen to 28s. Under the Act of 1924 minimum rates again became legally enforceable and the District Committees steadily raised them so that the average of 28s. at the beginning of 1925 had risen to 31s. 8d. at the end of 1926.

When the minimum wage was first introduced the Agricultural Wages Board was criticized for fixing hours of work as well as wages. This criticism was founded on a misapprehension. It was evident that merely to fix the amount of the weekly wage and leave employers the right to demand an unlimited amount of work for it would enable any unscrupulous employer to defeat the object of the act. The board laid down the number of hours to be worked for the minimum wage and fixed the payment, at a higher rate per hour, for overtime. The board also fixed special rates for those classes of farm workers, such as shepherds, stockmen and horsemen, whose normal occupation necessitated longer hours of work.

Agricultural wages had been from time immemorial, paid partly in kind. The custom was so well established that when the Truck act was passed prohibiting payment of wages generally in kind, agriculture was expressly exempted from its provisions. The most common form of payment of agricultural labourers in kind was board and lodging, the "living-in" system being very common in Scotland, the north of England and parts of Wales. (See AGRICULTURAL LABOURER.) In all parts of the country the provision of a cottage, either rent-free or at a nominal rent, was general, and other forms of part-payment in kind were the supply of fuel, milk, and potatoes. The Agricultural Wages Board expressed the

opinion that the abolition of all such allowances and perquisites was desirable, but after careful examination they decided unanimously that this was not then practicable. They therefore defined those allowances which might be given in part-payment of the minimum wage and drew up a scale of the amount which could be deducted from the cash wage in each case. Minimum rates of wages were also fixed for female workers and for boys.

The conciliation committees under the act of 1921 and the district wages committees under the act of 1924 adopted the principles and followed the lines laid down by the first Agricultural Wages Board, the only important variation being the raising of the age at which the rate for male adults applies from 18 (at which it was fixed in 1918, mainly on the ground that military service was compulsory at that age) to 21. In all other material respects the system of agricultural wages now prevailing is that established under the Act of 1917. (R. H. R.; R. E. S.)

AGRICULTURE: A GENERAL SURVEY. Agriculture is so primitive and fundamental an art, the beginnings of which so far precede any documents, that any attempt to write its earliest history becomes a matter of surmise and unverifiable conclusions from general principles. It is reasonable to suppose that prehistoric hunter man began by learning to tame the young of certain species, which proved to be fertile in captivity and could be attached to his wanderings. At probably a later stage tribes that gathered certain grains of food value began to make provision for future years by scattering a portion of the seed and effecting some rough clearance of the soil. They took the desirable grains with them in their wanderings and by sowing them they learned to become independent of return to the original centres of growth. When any remains of the early settlements emerge, they reveal evidence of animals and cultivated plants. For example, predynastic tombs in Egypt, an early Sumerian house in Mesopotamia (3500 B.C.), and lake dwellings in Switzerland and Italy associated with neolithic man, have yielded grains of wheat of a comparatively advanced type, which must have been preceded by long ages of culture. Flax and barley were also grown. It is significant, however, that no wild species can be assigned as the origin of any of our widely cultivated plants and the same complexity and uncertainty gathers round the sources of the domesticated horses, sheep, oxen and pigs. With the exception of maize and barley, the cultivated plants are polyploids, *i.e.*, the number of chromosomes in the cells is a multiple of the diploid number which characterizes the normal species. This

Soaring birds and harrowing. From the Louterell Psalter, an illuminated manuscript of the early part of the 14th century. ("Vetusta Monumenta," vol. 6, Pl. XXII., fig. 7)

points to a probable hybrid source; but whatever the origin, the polyploidy provides material susceptible of the variation on which selection can work, even when it is not attended by giantism or an excess of vigour which would naturally draw the attention of the early cultivator. Though no wild species can be fixed upon as a starting point of our cereals, Vaviloff has argued that the existing distribution of varieties points to certain centres as the original fountain of the cultivated races, these being regions which are to-day characterized by a concentration of varieties in the cultivated fields, where a host of forms occur not yet segregated into distinct races and shade off into weed forms which equally inhabit the uncultivated land. Vaviloff thus indicates the highlands of south-western Asia, particularly Afghanistan, as the probable

centre of the soft and club wheats; northern Africa as the home of *durum* wheats, while *einkorn*, a primitive wheat cultivated in prehistoric times, may have had its origin in Asia Minor. Still another race, *emmer*, perhaps the most ancient of cereals, is found in patches all over the old world and only among isolated and backward peoples.

But if we can arrive at some conclusions respecting the earliest forms of our cultivated plants and animals, the history of the growth of husbandry must ever remain a blank. When agriculture does emerge in written history in the time of the Greeks and Romans (*see* GEOPONICI), it is already a highly developed art, which had behind it long centuries of empiric progress, the fruit of observation and of trial and error. Cato, Varro, Virgil, Columella, the elder Pliny, describe an elaborate system of farming, embodying many principles, such as the value of leguminous crops as a preparation for wheat, for which modern science has only recently found an explanation. The methods of growing corn, vines and olives then prevailing had not been substantially altered down to the middle of the 19th century, and the sculptured representation of a sacrificial bull, lamb and boar on the *plutei* of Trajan in the Roman Forum bear witness to an advanced state of stock breeding. Roman agriculture is indeed the foundation of modern farming, and though over the greater part of Europe it became submerged with the irruption of the barbarians, its traditions probably never died out in the favoured regions, but shaped and were resumed in modern systems of farming.

Mediaeval Farming.—The course of farming in England that we find in early days is in many respects common to all the invading Northern peoples who drifted across Europe; it finds its parallels in all countries north of the Alps, in Russia and in India. It is not uniform, for on the western sides of the islands, in Wales and in Ireland, we find evidence of an earlier system, which is reflected to-day in the grouping of the houses into scattered hamlets instead of into the larger villages characteristic of the more purely arable districts of the Midlands and Eastern England. Whether the organization derives from an original communal ownership of the land and even of its produce is still a matter of dispute, but when records begin the system had passed out of this stage and to some extent had been shaped by feudal theory (*see* ENGLISH HISTORY).

The Manor.—The unit of land holding and cultivation was the Manor (*q.v.*), of which there might be one or more within the parish. The land was held at one or more removes from the king by the lord of the manor, from whom the tenants held in return for various services and with varying degrees of freedom. The cultivated land lay in three, or some multiple of three, open arable fields, divided into strips of one or one half acre, separated by baulks of rough grass and terminating in still wider baulks, the headlands on which the cumbrous ox team and plough could turn. On heavy land the strips were steeply ridged to throw off the water and this ridge and furrow still persists in many parts of the Midlands which have long been laid down to grass. In some places the old strips still defy cultivation, because of the labour that would be required to throw down the ridges and the infertility of the subsoil that would be bared in their crowns.

The three fields were cropped on a fixed rotation of winter corn (wheat or rye), spring corn (barley, oats, peas or beans, or mixed corn) and bare fallow. In each field the tenants held a certain number of scattered strips, the original intention being probably to give to every man a share of the good land and the bad, and mingled with them were the strips held by the lord and constituting his demesne. Each tenant farmed his own strips but was required to give a stated number of days' service to cultivate the demesne strips, services which gradually became commuted into payments in money or in kind. At a certain date after harvest the arable land was thrown open to the cattle to wander over, and this of itself prevented any growth of fodder crops. On the lower land by the river would exist an area of meadow land to be laid up for hay and again divided in proportion with the arable land. The tenure of the particular strips for the year was often balloted for, a practice which still endures in

places, as at Yarnton near Oxford. After hay harvest or Lammas the meadows were thrown open for common pasturage, hence the name of "Lammas fields" which still obtains. Besides the arable and the meadows the manor embraced a certain amount of "waste," the origin of what to-day are known as "commons" (*q.v.*). On this the tenants had right of pasturage and in suitable districts of *turbary*, that is, the right to cut turf or peat for fuel. It also provided fern for litter, reeds or heather for thatching, furze and brushwood for firing, rushes for the floors and other purposes, rough timber for fencing and building, stone, gravel and sand.

Production.—The farming that prevailed under these conditions was necessarily inefficient. Some manure appears to have been made by strewing roughage, marl or clay in the folds and in the "garsons," the little enclosures by the village into which the stock were driven at night; but the crops must have mainly depended upon the inherent fertility of the soil. The sheep were folded upon the fallow by night, though tenants were often obliged to put them upon the lord's land only. In the west where the area of unoccupied land was greater, there is evidence of a practice of moving the arable fields continually, whereby some fertility would be accumulated while the land lay in rough pasture. Of extraneous fertilizers there were none; in areas on the chalk the practice of sinking pits into the chalk and spreading it on the land may have endured, for it is mentioned by Pliny in his account of Britain, and the traces of the old pits that remain in certain districts indicate a long continuance of the process of chalking and marling. The level of production was exceedingly low. Walter of Henley, who wrote early in the 13th century the standard treatise on the management of an estate, advised the sowing of two bushels of wheat per acre, which ought to yield threefold. From the context this would be a minimum, and the contemporary author of "Hosbonderie" says that barley might yield eightfold, wheat fivefold, rye sevenfold, peas and beans sixfold, and oats fourfold. From other sources we shall be justified in estimating the level of production of open field land in mediaeval times at a yield of about 10 bushels of wheat to the acre.

If the conditions of cropping were bad the live stock were in a worse state. The stock of all the tenants and of the lord herded together and were driven afield and tended by the village cowherd, shepherd and swineherd respectively. Which class of stock prevailed depended to some extent upon the class of land; in the open down and heath country sheep were a feature, the acorns and mast of the woodlands finished off the swine before the winter. Pannage (*q.v.*) for so many hogs is a common entry in Domesday as an appanage of a particular holding. But with this mixture of everybody's stock little in the nature of selective breeding could be practised. Walter of Henley insists on the value of good boars, but in general the bull and the boar were common to the manor—the result was a "haphazard union of nobody's son with everybody's daughter." Whatever disease came along ran riot through the whole herd or flock. Oxen were chiefly kept for work, and Walter of Henley considered an ox at work should consume half a sheaf of oats a day. Though the greater speed of the horse was recognized, it required more care, cost more to feed and was "carriage" instead of meat when worn out. Cows were kept for milk and the milk was mainly converted into butter and cheese. In the early summer they grazed on the "waste" and marshes or were tethered on the grass baulks; later they had the aftermath of the meadows and the stubbles. With the advent of winter the worn out oxen and the old cows were killed off and salted down:—"For Easter at Martinmas hang up the beef." During winter the cattle subsisted in the yards on hay, pea and bean haulm and straw. Rarely were cattle stall-fattened and the open field farmers sold most of their calves for slaughter. Sheep were from the earliest times an important element in English farming because of the value of their wool. The ewes were often milked, the toothless "crones" being killed for meat. During the open weather they lived on the downs or the waste by day and were folded on the fallow by night, in the depth of winter they were housed or folded and fed upon whatever roughage was available. Swine afforded the chief meat of the

community; they scavenged for a living in spring or summer and fattened upon the "pannage" of the woods. A few were specially fattened upon tail corn and the brewers' grains, for the barley that was grown was very largely turned into ale. The manor aimed at being self-supporting both for food and clothing. Rarely had even the lord any margin of corn for sale; the chief money revenue was derived from the live stock, wool, skins, and dairy produce.

Enclosures.—But the strict manorial system early began to be broken into. The lords had often retained meadows and made enclosed fields which they either farmed themselves or let. Little holdings grew up by sufferance on the waste, occupied by "tradesmen" in the villages or other cottagers who also shared in the common grazing. The rising value of wool in the late mediaeval times tempted lords to aim at enclosures of the arable, and recurring dearths and epidemics, of which the Black Death is the most notable, deprived the land of its labourers and facilitated the putting together of larger units of cultivation. From the earliest times the substantial independent farmer, represented by Chaucer's Franklyn, was a feature of English country life. Not only were the old feudal services commuted into rents, but by new intakes from the wastes or by fencing off portions of the open fields the tenants began to enjoy land in severalty. In Tudor times the process of enclosure was in full swing, though the legislature was opposed to, and public opinion was loud in denunciation of, a movement which appeared to diminish corn growing and the rural population. But the driving force was the growing commerce of the nation. Not only did both landlords and tenants want something to sell and looked upon the land as the basis of a business rather than a subsistence, but the small holders who had been barely able to exist upon their little parcels of cultivation found other and more attractive outlets in the growing commerce and industries.

The New Farming.—It was towards the close of the Tudor times and in the early seventeenth century that the new farming began. Increasing intercourse with the Continent and particularly with Flanders, where some of the old Roman tradition had persisted, brought new crops and stock and new methods into England. Sir Richard Weston (1591–1652) who farmed in Surrey in Charles I.'s time, is credited with the introduction of turnips, clover and other sown grasses, and these crops providing winter keep were the foundation of the improved system of agriculture. With them cattle could be fattened and maintained during the winter; at the same time farmyard manure was made in quantity sufficient, with the help of the clover which enriches the soil in nitrogen, to raise enormously the whole level of production. The new farming could, however, only be practised on enclosed farms; on the open fields clover and turnips would be every man's property as soon as the common stock were turned on to them.

Turnips and clover were not the only introductions from the Low Countries; most of the commoner garden vegetables, as cabbages and cauliflowers, carrots and parsnips are owing to the same source. Fruit trees too were "fetched out of Flanders." Richard Harrys, fruiterer to King Henry VIII., bought "105 good acres in Teynham which he divided into 10 parcels, and brought plants beyond the seas and furnished the ground with them," which land "hath been the chief mother of all other orchards for these kindes of fruites." Hop growing also had a similar origin.

Doubtless the same thing happened with live stock, but here the evidence is more meagre because the descriptions of the early writers are so imperfect. But it would seem probable that the large long-woolled white-faced sheep were originally of Roman origin, and the Kents or Romney Marsh, the Lincolns and Leicesters, all on the eastern side of England, may well have been derived from a very similar sheep which is still found in Flanders. The importations may, indeed, have been earlier, for the English long wool was famous in mediaeval times and was among the first of the staple articles of export, its importance being still commemorated in the "woolsack" on which the Lord Chancellor sits. The earlier long wool chiefly came from the Cotswold country, the home of the other white-faced long-woolled race of sheep, and

this possibly may be a remainder from Roman occupation. The black and white cattle which have always been about the Eastern counties were certainly of Low Country origin—the modern Frisian, Holstein or Dutch Cattle. We may even surmise that some white race of Roman origin (either directly or at second hand from the Rhine provinces) went to the making up of the Short-horn race, whose hybrid origin is betrayed by the mixed white and red in the coat colour of the roans.

Enclosure Laws.—The progress of enclosures which has been described grew apace in the 18th century. Whereas in early days it was opposed by Parliament, in the 17th century it became possible to obtain sanction for agreements from the Court of Chancery, and from the time of Anne a strictly legal procedure by private Act was made available (*see COMMONS*). Commissioners were appointed to make the award and apportion the several holdings to the tenants of the open arable fields, but a private Act remained necessary until the General Enclosure Act of 1845. Under the acts the commissioners could proceed to an award although a minority of the parties interested, one-eighth or even one-third, refused to agree. In certain counties—Suffolk, Sussex, Kent, Essex, Somerset, Devon and Cornwall, the marches of Wales, Cheshire, Lancashire and the four northern counties—enclosures were early and were but rarely effected by Act. Possibly from the nature of the land the rigorous common field arable had never been usual in them. It was in the great corn growing areas of the Midlands, Yorkshire, Lincolnshire and Norfolk, that so much enclosure by Act took place in the 18th and early 19th centuries. After 1760 the process was much accelerated by the growth of industry and population even before the Napoleonic wars created so great a call for good production. Valuable, indeed necessary, as enclosures were to the nation from the point of view of production, so great a change in the economy of the country-side could not be effected without much serious, if temporary, dislocation of labour and some permanent change for the worse in the condition of the poorer classes. Often the lord and the larger tenants took the opportunity of enclosure to put the land down to grass, so that a single shepherd would take the place of a dozen men who had formerly worked on the village land. The enclosures themselves may have been fair enough in their apportionments, though it would always have been easy for the lord and the bigger farmers to over-weigh their poorer neighbours, but many cottagers who had no arable and therefore no title in the award found their customary rights of grazing swept away with the commons. There were those who held that the commons encouraged an idle race of casual labourers and poachers, but the other side of the picture, the destruction of a thrifty peasantry, was the theme of many writers in the 17th and 18th centuries.

Arthur Young, himself an unceasing advocate of enclosure, deplored the evils that had resulted therefrom. "By nineteen Enclosure Acts out of twenty, the poor are injured, in some grossly injured. . . . The poor in these parishes may say, and with truth, *Parliament may be tender of property; all I know is that I had a cow, and an Act of Parliament has taken it from me.*"

The Agricultural Labourer.—With enclosure at any rate began the creation in rural Britain of a race of landless men, dependent for employment upon the larger holders of land; and though the darkest days of this class did not come until the close of the 18th and the first third of the 19th century, when the pauperization caused by the old Poor Law became universal, the lot of the agricultural labourer, still the worst paid and worst housed section of the community, was established. Thomas Mozley writes of his parish in Northants in 1829, "There were many farmers, several yeomen, very many small freeholders, as many tradesmen as the place could find work or customers for, and not one single labourer, in the sense of an independent workman offering his labour for wages, but a multitude of paupers." The labourer class was also recruited from those yeomen proper who obtained small farms after enclosure but were unable to hold on to them. It requires neither fraud nor force to displace the small proprietor; the mere pressure of economic change is sufficient. A run of bad seasons, the constant temptation to mort-

gage, the inheritance by a widow, and the neighbouring proprietor who wants to add land to land finds his opportunity, especially where, as in England, land has also for so long possessed a non-economic social value. Special opportunities were also offering to active men in industries and commerce, and since many of the old yeomen farms could produce but the barest living for their occupier, they were sold and merged in larger holdings because the owner was no longer content with the income derivable from them. In other countries peasant farming has subsisted largely because there were no alternative occupations with a higher standard of living within reach and because the layout of the land on the open field system persisted and did not permit of putting together large units of farming. The open field system nevertheless persisted into the 19th century; and even in 1927 a non-enclosed parish farmed on the old English plan can be seen at Laxton in Northamptonshire, while the parishes of Epworth and Haxey in the Isle of Axholme remain in strips, though the owners crop them as they please.

The Norfolk System.—The improvement in method of farming possible on the enclosed land soon took effect. Early in the 18th century we find in operation what afterwards came to be called the "Norfolk" or four-course rotation. In consequence England became a corn exporting country during the first half of the 18th century, until the growth of population manifested itself with the development of industries. This epoch of British farming which became systematized in the early 18th century and endured until 1840, may be described as that of the conservation of the resources of the soil. The land was usually cultivated on a four course system of two corn crops, alternating with turnips and a leguminous crop—clover or beans. The leguminous crop gathered nitrogen from the air and maintained the stock of this indispensable element of fertility at a comparatively constant level, despite the wastages that were going on. The turnips and the hay and straw provided for the making of farmyard manure, whereby there was returned to the soil the greater part of the valuable materials that the crops had taken out. Nothing left the farm except the nitrogen, phosphoric acid and potash sold away in the wheat and barley, the meat, milk and wool. Strict covenants prevented such wasting of the soil capital as would occur from the sale of hay or straw or roots, or the too frequent growth of salable corn crops. Under this system the average production became more than double that of the mediaeval farms. Arthur Young speaks of 24 bushels of wheat as the average yield per acre; John Bennet Lawes, writing of Hertfordshire as he knew it when he began his experiments at Rothamsted about 1835, sets the yield at 20 bushels, and the lower estimate is probably nearer the mark for the whole country. This level of production, which we may compare with the six to ten bushels of mediaeval open field farming, could be maintained indefinitely. The limiting factor was generally the supply of nitrogen, and this depended upon the recuperative actions of the leguminous crop in the rotation and of bacteria in the soil which make use of the organic matter supplied by the roots, the stubble and the straw, as against the removals in salable produce and the wastages that occur in the making of farmyard manure and in the soil itself under particular conditions, as washing out and waterlogging. The balance that was established was sufficient to maintain the yield at the level of 20 bushels per acre of wheat.

Live-stock and Other Improvements.—Other improvements in agriculture were simultaneously in progress; great areas of waste land were being added to cultivation, especially on the heaths and light soils which before turnips and clover were introduced became immediately exhausted. Small's plough, the horse hoe, the drill, the threshing machine, were all inventions which took practical shape in the 18th century and did much to add to the effectiveness of the farming operations. Drainage and the systematic amelioration of the land which had been impracticable on the open field system were now taken up vigorously, though the wide extension of field drainage had to wait until the invention of drain tiles in the next century.

Moreover, with the prevalence of enclosed fields, the improvement of live stock could be taken up with some prospect of rapid

achievement. Robert Bakewell (*q.v.*) was the pioneer, and though he was unfortunate in selecting the Longhorn cattle to work upon, his creation of the Leicester breed of sheep persisted and led to rapid amelioration of all the long-wooled sheep. His methods were taken up by other men; Charles Colling (*q.v.*) made the Shorthorn breed, and John Ellman (1753-1832) the Southdown sheep which has been the progenitor of all the other "down" breeds. England developed a race of breeders who combined the instincts of the fancier with certain definite principles. They began by selecting their breeding stock for conformity to an ideal type in which the meat was laid on in the most valuable places; by close line-breeding, even by inbreeding, the type was fixed and the "pedigree" sires became capable of stamping their own type in a few generations upon the common country-bred stock. Early maturity, the capacity to grow rapidly on good food, proved to be equally obtainable by selection, and the result was that in the 19th century Britain was possessed of a number of definite breeds of cattle, sheep and pigs that were doubly or trebly more efficient than were the old unimproved stocks. Their value may be gauged from the way the flocks and herds of the new countries of the world have been populated with stock of British origin. Shorthorns, Herefords and Devons are the great meat producers of the Americas, Australia and New Zealand; the only non-British breeds that have achieved any world-wide extension are the Merino sheep because of their wool and adaptability to arid climates, and the Friesian cattle because of their unrivalled milk yield.

Capitalist Farming and the Great Landlords.—The new agriculture which had grown up in response to the rapid increase of population under the beginnings of industrialism and had been overstimulated by the excessive prices that prevailed during the Napoleonic wars, fell upon evil days with the break in prices and the restoration of a gold standard that followed the final peace in 1818. But it had accomplished its purpose of providing food for the nation from its own land, and it had completed the conversion of British agriculture from a system of peasant cultivation into one of capitalist business, small indeed in the main, but characterized by the employment of labour. In no other country has this development proceeded so far. Prior to the disturbances arising out of the late World War most countries in Europe other than France, Switzerland and Belgium, could show vast estates farmed as single units and owned by the territorial nobility, but there was little or nothing of a middle farming class between the domain owners and the peasants, carrying on farming as a business on land rented from the large proprietor. In Great Britain the political, social and sporting privileges attaching to the possession of land early led to the building up of great estates, but the owner found the best use of his property in letting it again to tenants, who on their side took advantage of the opportunity for employing their limited capital in the business, by which they could derive a bigger income from it than if the greater portion were locked up in ownership of the land.

Thus in England the great landowners were the leaders of agriculture along its path of progress in the 18th century, even though most of the actual improvements, especially in stock breeding, were the work of tenant farmers like Bakewell, Colling and Ellman. A few large proprietors led the way; they created the atmosphere of enterprise and confidence in the industry, and they rendered better farming possible by their expenditure on reclamations and buildings. They introduced the improved live stock to their tenants and they enforced sound methods of cropping by the covenants inserted in the conditions of tenancy. Prominent among them were the 2nd Viscount Townshend (*q.v.*) Pope's "Turnip Townshend," who devoted himself to the improvement of his estate in Norfolk on a basis of turnip growing, with the use of the drill and the horse hoe. He is generally credited with the Norfolk four-course rotation, but it had been evolved before his time and he only gave to it a wider extension. The ideas that Townshend put into practice were chiefly derived from Jethro Tull (*q.v.*) of Berkshire, the greatest original thinker about farming processes that England had then produced. His "*Horse-Hoeing Husbandry*," published in 1731, was the basis of all im-

provements in the operations of cultivation during the 18th and early 19th centuries. A little later Townshend's neighbour, "Coke of Norfolk," 1st Earl of Leicester (*q.v.*) made a productive estate at Holkham of what had been little more than a rabbit warren, and became famous for his annual gatherings, the Holkham sheep shearings, where all the improving landlords and farmers of the day met and exchanged their experiences. There, too, the improved live stock of the time could be seen and judged. The duke of Bedford was equally active and held similar meetings at Woburn. A little later we may single out the earl of Egremont in Sussex, and in Scotland Hope of Rankellor and Sir John Sinclair of Caithness, first president of the newly formed National Board of Agriculture.

Arthur Young.—But the most active promulgator of the new methods was Arthur Young (*q.v.*). The younger son of a parson with a small property, Young began by farming, but with constant ill success. He soon found his proper *métier* in writing, and from 1767 to 1795 he published those vivid accounts of the farming, the men and manners of England, Ireland and France, which have become classics of observation and shrewd judgment. In 1784 he began the publication of the "*Annals of Agriculture*," which embodied contributions from all the men of the time interested in agriculture, even the King himself. When a board of agriculture was established in 1793 Young became its secretary and was responsible for a series of county surveys of the state of farming in England which, if unequal and in some respects inferior to Marshall's *General Survey of the Rural Economy of England*, remains our most trustworthy source of information. Young was pre-eminently a diffuser of knowledge; he had a sound knowledge of the general trend of agriculture, witness his unceasing advocacy of enclosures, and a quick eye for improvements of method. If his zeal sometimes outran his judgment in his commendation of innovations, his lively style always exacted interest and made him for 40 years a most effective stimulus towards the reform of farming. Rarely can a farmer be instructed in the method he is to follow, but he can be excited to think out a novel adaptation to his own conditions.

Period of Scientific Progress.—We may take the accession of Victoria as the beginning of a new era in British farming. The occupiers of land had slowly adjusted themselves to the new conditions, after the shock caused by the break in prices at the end of the Napoleonic wars. Confidence in agriculture was returning and a new race of landlords was growing up imbued with the idea that the rapid development of science then in progress could be applied to the operations of the farm. In 1838 some of the leaders, among whom perhaps the most active was Philip Pusey, founded the Royal Agricultural Society (*see AGRICULTURAL SOCIETIES AND SHOWS*), which gave a powerful stimulus to the improvement of stock, to experiments in cultivation and manuring, and to the introduction of machinery. Another small landowner, John Bennet Lawes (*q.v.*) of Rothamsted, Herts, was beginning that fundamental series of field experiments which took formal shape in 1843 when Lawes secured the association of a young chemist, Joseph Henry Gilbert. At Rothamsted was laid the foundations of our knowledge of the use of fertilizers and the nutrition of animals. This period is indeed marked by the introduction of artificial fertilizers. Previously there had been some empiric knowledge of the fertilizing value of such waste materials as woollen rags, soot, and bones, but the supplies were limited and the employment only local. The first consignments of Peruvian guano and of nitrate of soda arrived in 1835; in 1843 Lawes began the manufacture of superphosphate, and his early experiments showed the value of the ammonia salts which could be made from the by-products of gas-making, then becoming general. Other sources of phosphates than bones were rapidly discovered and about 1860 the great deposits of potash near Stassfurt began to be exploited.

At the same time the science of agricultural chemistry was being explored and the theory of the nutrition of the plant—what it draws from the soil, the water and the air—a theory of which Justus von Liebig (*q.v.*) had given a brilliant preliminary sketch in his British Association address, provided a rational basis for

manuring. By 1850 the manufacture of artificial fertilizers was in full swing and though all too many farmers lagged behind in their application, their use, together with the employment of foreign feeding stuffs like linseed and cotton cake, the fertilizing ingredients of which found their way to the land through the farmyard manure made by their consumption, had by 1870 raised the general level of production from British land from 20 to 30 bushels of wheat per acre. As already described, up to 1840 an average of about 20 bushels per acre was all that the land could yield when the farm was strictly self-contained; it was the extraneous sources of fertility which made the higher yields possible. Fertilizers and feeding stuffs were indeed not the only factors at work, though the other improvements influence perhaps more the extension of the cultivated area than its increased yield. Field drainage was applied to great areas of heavy land under the influence of James Smith (1789-1850), of Deanston in Scotland, and of Josiah Parkes (1793-1871) whose demonstrations of the value of drainage (*q.v.*) became easy of application with Scragg's invention in 1845 of a machine for moulding cylindrical tiles. Smith drained shallow, 30 inches; Parkes put his drains in at 4ft., and much of his work has been in consequence wasted. Only since the great controversy between the two schools has it become clear that Smith's is the way to deal with ordinary heavy land which suffers because it cannot get rid of the rainfall, whereas Parkes's is the best method to cut off underground water rising from below. The improvements in cultivating machinery continued and in 1853 Crosskill put an efficient reaper at the farmers' service. The steam plough was designed and ever since has had a valuable if limited field of action. Pedigree stock made rapid progress; one by one the existing breeds of cattle, sheep and pigs became differentiated; breed societies and flock and herd books grew up. Improvements in crops also followed; Shirreff, Chevalier, Le Couteur and Hallet introduced the idea of "pedigree" into cereals.

In these years from 1850 to 1874 farming was a prosperous business and money was poured into the land; British farming may then be said to have reached its high water mark of technical excellence. Of some farmers it was reported that they offered a reward to anyone who could find a weed on their cultivated land; no other country could show such yields of corn and roots; men came from all over the world to buy British live stock with which to improve their native races.

The Great Depression.—All this prosperity culminated in the high prices occasioned by the Franco-German war; in 1874 a turn in the tide was manifest. A trade depression set in which limited the purchasing power of consumers; a run of bad seasons, culminating in the disastrous wet and cold year of 1879, brought ruin to many farmers. Other major causes beyond the control of farmers were at work to reduce prices. The growth of railways and the development of steamship traffic opened up the international traffic in agricultural produce, and the wholesale settlement of the new countries, particularly of the middle west of North America, gathered way. The area of cultivated land in the world with wheat as the staple crop grew apace, faster even than the population; wheat prices fell year by year until 1894. The average *Gazette* price of English wheat was 54s. 3d. for the decade 1865-74, 46s. in the next decade, and continued to fall to 22s. 10d. in 1894. Within the 20 years 1875-1894, 124 million acres of land were added to the cultivated area of the United States alone, and the corresponding increases in Canada, S. America, Australia and New Zealand were considerable.

The other great factor was the appreciation of gold which began when Germany started to form a gold reserve after the war of 1870 and was accentuated by the falling yields from what had been the chief gold-producing centres of California and Australia. The situation was not rectified until the Transvaal became a big producer in the nineties of the last century. The prices of all commodities fell, wheat more than the rest [Sauerbeck's index, *i.e.*, all commodities fell 40%, wheat 51%], and some economists have considered that to this cause alone was due the fall in agricultural prices and the resulting depression. But the vast increase of production must have also had its effect or the demand from

the rapidly growing population would have counter-balanced it. During this period there was always a surplus of wheat and it was being grown at less than the cost of production, indeed it has been said that the only profit the pioneering American farmer made out of all the plenty lay in the eventual appreciation in value of the land he had settled.

Whatever the ultimate causes of the break in prices it had a disastrous effect upon British farming. Neither farmers nor landlords realized how continuous the fall was going to be, or how completely indifferent would the price remain to the occurrence of a short crop at home; farmers could not readjust their methods and in many cases landowners did not reduce their rents in time to avoid a crash. Much of the old perfection of British farming had

MEDIAEVAL HUSBANDRY

Feeding chickens. From the Louterell Psalter, an illuminated ms. of the early 14th century. ("Vetusta Monumenta")

to go because of its expensiveness in labour, for during the whole of the period wages were tending to rise rather than to fall. Farm after farm was thrown upon the owners' hands; in Essex great areas of clay land became for a time derelict or were let to Scotsmen who would undertake to pay tithes and rates. In some cases the landowners had to farm themselves on an extensive scale, in others farmers who had acquired an art of cheap management had farm after farm thrust upon them until they were operating areas of 4,000 to 10,000 ac. These big businesses which grew up towards the close of the century are not reflected in the statistics, for the separate farms were still returned in the rate books as units. Indeed they were farmed as units, each with a bailiff but on the common system which the farmers had found to work; the buying and selling only were centralized. Though prices did turn slightly after 1895 it was not until the close of the century that the conditions began to appear at all stabilized. By that time men had learned to cheapen their methods in the purely arable districts and in others the growing demand for milk had afforded an outlet. The Essex clay lands came back into use, if not under the plough, with a new race of Scotch and Devonshire milk producers. Prices of meat and wool had fallen though not to the same extent as with cereals, and the distress in the west and north of England had never been so great as in the purely arable countries. In some districts special crops solved the farmers' difficulties; a great potato industry developed in the Fen country, where energetic men with intensive methods built up large holdings out of the bankrupt small farms: but the price of potatoes, like that of milk, was made at home, foreign competition being negligible here, while the demand was growing with a larger and more prosperous population. The growth of vegetables, fruit and flowers provided also an expanding industry, and the demand for such things increased with the rise in the standard of living.

Loss of Arable Land.—But such commodities provided the exceptions; in the main the farming community had to meet the depression by reducing expenditure, despite the resulting fall in production. The acreage only under wheat in England, 3,337,000 in 1872, had shrunk to 1,745,000 in 1900; yet there was no accompanying increase in the yield per acre such as should have attended the abandonment of the poorer land, without taking into consideration the improvements in the varieties grown and in the supply of fertilizers. The chief resort of the English farmer in order to meet the situation was to lay his land away to grass. Thereby he shifted his production towards the more remunerative live stock and at the same time reduced the labour bill, because on grassland one man may suffice for 200 or 300 ac., whereas on the arable land about four men per 100 ac. were then employed. Only when dairying on grassland is a staff required comparable with that employed on the ploughland. Between 1872 and 1900 the area of land under the plough in England was reduced by over 2½ million ac., or nearly 20% of the amount in 1872. There were some notorious examples of these changes; in one case on the Berkshire Downs some 4,000 ac. of ploughland were converted into a sheep ranch tenanted only by a few shepherds, the old farmhouses and

hamlets perishing away in desolation. In England and Wales the agricultural population diminished between 1871 and 1901 from 1,269,371 to 951,674, that is, by nearly one quarter. In Scotland the reduction in arable land was not appreciable, but a similar saving was effected by lengthening the duration of the leys in the rotation; the four-course shift became a five- or a six-course, with two or three years of temporary grass instead of one.

For all the reduction of cultivation and the lower standard of farming the period was not entirely one of retrogression. Improvements in the quality of live stock, especially in the direction of early maturity, in the production of milk, and in the special branches of potato growing, market gardening and fruit growing continued. The self-acting reaper and binder began to be imported in 1873 and proved the great labour-saving implement of the period, though at the outset it only intensified the pressure of competition, since it was worth more to the wheat grower in new countries short of labour than it was to the British farmer. This distressed state of agriculture became the subject of more than one royal commission and parliamentary enquiry, none of which, with protection ruled out as contrary to national policy, could suggest any substantial alleviation. The one legislative action of importance was the creation in 1889 as a special department of State of the Board of Agriculture whereby the importance of agriculture in the national economy was recognized, no other industry having this kind of representation in the machinery of government. The new Board took over certain existing services such as the collection of statistics, the control of scheduled animal diseases, the administration of tithes, enclosures, and university and college estates, and was also charged with one function of a constructive character, the allocation of £5,000 a year for the assistance of agricultural and dairy schools.

Agricultural Instruction.—From about 1890 onwards began the first systematic attempt at agricultural education and in its train followed some new beginnings in research. The great start made at Rothamsted had been left solitary and unaided, though other countries were copying its methods and extending them into all the fields of science which bear on agriculture. The movement was too young to have any effect on the industry before the close of the century; it had to overcome the intellectual inertia of a class which had always been indifferently educated and had no opinion of book farming, while the new scientific teachers had to learn what was good in the practical man's outfit and to recover from their own mistakes. One new fertilizer had been added to the list available for the farmer, namely, basic slag, a phosphatic by-product of the steel industry which was to do much to improve the growing area of grass land. But owing to his poverty the British farmer was not using fertilizers as much as he might have done, and the greater part of the British production of sulphate of ammonia was being exported.

The period from the beginning of the century to the outbreak of the World War was one of steady recovery and quiet progress under the favouring wind of slowly rising prices. Knowledge was growing, both from the example of successful practitioners under the new conditions, and from the technical instruction that was becoming more generally diffused. Statistically the industry continued to decline; the arable land of England diminished by a further million acres between 1900 and 1914, nor was there any compensating increase in the numbers of live stock, though the output was improving as better methods of feeding and breeding brought the animals earlier to market. All over the country examples could be found of progressive and prosperous farmers who were taking advantage of the resources science was increasingly putting at their disposal. But many were still set in old ways; mindful of the bad times that were not far off they sought the path of safety first and were distrustful of all enterprise that might cost money. In the use of lime, fertilizers and other ameliorations of the soil our farmers were falling behind their competitors in Holland, Denmark and Germany, just as in the applications of machinery they could not rival the farmers of America and Australia. Labour was still too cheap in the agricultural counties of England; farmers still clung to the traditions that had answered when wages were 7s. a week and wheat over 6s. a bushel.

Marketing.—Above all the weakness of the British farmer as an economic unit was being exposed. The rapidly growing population was to an increasing extent being fed from overseas; in the five years preceding 1914 the United Kingdom only produced 42% of the food it consumed as measured in calories, in particular it only grew 20% of the wheat it needed. Great Britain was the one open market for the agricultural surpluses of the whole world, for the one or two small countries that also persevered in a free trade policy were themselves exporters of agricultural produce. In consequence great commercial interests grew up to exploit this import trade, interests that could impose upon the aspirants for a place in the British market those conditions of uniformity of produce, standardization of output, and attractiveness of packing, which made for ready sale. Our competitors by the mere fact of dependence upon an export trade were marshalled into co-operative societies, and through this discipline the peasant farmers of other countries secured all the advantages of marketing which might have been expected to belong only to the big businesses. The typical British farmer, who in his day had been a not inefficient unit for the sale of his staple produce and could look down upon the exploitation of the peasant, was loath to forgo his individuality and slow to recognize his weakness in the world's markets. The lack of leadership and organization was all a part of the want of public confidence in an industry which had become somewhat remote from modern life. The great landowners no longer regarded agriculture as a money-making business; they maintained home farms because of the traditional association of the English gentleman with the countryside and because the exhibition of pedigree stock was a recognized form of social competition; but the lawyers, the bankers and the capitalists remembered the past and had no belief in the earning capacity of the land. No joint stock enterprise to produce food at home could hope to obtain public support, however much money might be forthcoming to exploit wheat or wool, tea or rubber or copra abroad. The farmers who were making money said little about it and trusted to obtain whatever capital was needed for their businesses, many of them extensive, from their friends or trade connections. Politically the farming interest did not count; in Parliament there could be no agrarian party, hardly even an agrarian member, because even in a purely rural constituency the more numerous labourers were not likely to vote with the farmers. Nor was there any policy upon which the agriculturists were united; although most farmers were still protectionists, such a measure was taboo to all parties so far as concerns food and even with the agricultural labourer the dread of higher prices outweighed the hope of better employment.

The one political measure of outstanding importance was the Small Holdings Act of 1908 which empowered County Councils to acquire land and equip it for small holdings and allotments (*see ALLOTMENTS and SMALL HOLDINGS*). This Act may be taken as one of the signs of a growing public interest in agriculture, of the feeling among thinking people that the urbanization of Great Britain was proceeding too fast and that some measures should be sought to check the drift of men away from the land. The triumphal march of industrialism from factory to factory had lost some of its attractiveness; statesmen no longer regarded the simple theory of Great Britain wholly given up to manufacturing, and exchanging its goods for food, as desirable or even safe. So the Small Holdings Act was an attempt to recreate the peasantry that had always been dying out in Britain, and to provide an access to the land for men whom circumstances had driven into the towns but who still felt a call to the soil. The growth of small holdings could do little towards reducing the volume of imports; the impulse was social rather than economic, but a small holding might give a jumping-off point for the energetic man who would move into larger and larger farms, and new blood was needed in the farming community. The statutory small holders rarely failed to establish themselves, but their numbers barely sufficed to keep pace with the wastage that was elsewhere going on (*see also post section on Small Holdings*).

The Development Fund.—Another measure of perhaps more far-reaching consequences was Lloyd George's Development Act of 1909, by which was set up a commission endowed with ample

funds, the function of which was to promote research and education in agriculture and to carry out other experimental work in rural industries which might help to restore prosperity to the countryside. Thanks to this fund British agriculture began to be provided with an adequate establishment for research and investigation, such as the United States, Germany and other progressive countries already enjoyed. Some results from research were already accruing. The plant breeder's improvements were quickly recognized by farmers, and Rowland Biffen of the Cambridge school of agriculture and Beaven of Warminster, working independently, had applied the principles which Mendel had been the first to bring to light, to the breeding of new varieties of cereals. Some of Biffen's wheats and Beaven's barleys were already being widely grown by farmers in the progressive districts and their success did more than anything else to convert farmers to a belief in the value of research.

One other technical advance may be noted. Towards the close of the period the tractor plough, driven by an internal combustion engine, began to appear in our fields. The new tool could be operated on a farm of ordinary British size, whereas the steam plough was only economic on an extraordinary acreage and had become an emergency implement only hired for special work. Imperfect as the motor implement was and still is, it offers potentialities of speeding up and economizing manual labour which have not as yet been fully realized.

THE WAR PERIOD

The war struck across all these projects of quiet development, and its first effect was to sweep the agricultural colleges and research institutes of all their students and younger staff for service in the new troops. For the first two years of the war farmers were told to get on with their business as usual but that they had no special part to play or contribution to make. Prices rose steadily but not abnormally, though here and there a special shortage would declare itself. It was towards the close of 1916, when the submarine menace began to assume threatening dimensions and harvests both at home and in America were deficient, that the new government called upon the farmers to assume a share in the fight.

The Food Production Department.—The Board of Agriculture, of which the new president was Rowland Prothero (since raised to the peerage as Lord Ernle), set up early in 1917 a Food Production department directed by Sir Arthur Lee (later Lord Lee of Fareham) and county committees were constituted with certain powers of directing the crops to be grown by farmers. Little could be done to enlarge the area under crop in 1917, but rapid surveys were made of land and to each county was assigned an area of land to be put under the plough, as far as practicable in corn and potatoes. Power was also taken to enter upon land that was being inadequately cultivated; services were organized to provide and distribute steam and tractor ploughs, horses and implements; labour was recruited from every possible source, including interned persons and prisoners of war, and the women joined in large numbers and rendered devoted service, training centres being set up to make them and other unskilled labour serviceable on the land. The supply of seeds, fertilizers, feeding stuffs, and other necessities like binder twine was organized, and the necessary transport (now under control) and credits for purchases overseas were arranged. Late as came the effort it was prosecuted with great energy, and even in 1917 the area under the plough was increased by a quarter of a million acres, in addition to 720,000 ac. of arable grassland sown to crops. An increase of 60,000 ac. of wheat, 150,000 ac. of barley, 620,000 ac. of oats and 260,000 ac. of potatoes was obtained in 1917 as compared with 1916.

Another section of the Food Production department promoted the cultivation in allotments of all the spare ground that could be found round the cities and towns, and saw to the supplies of seeds and tools. This movement (*see* ALLOTMENTS and SMALL HOLDINGS) was of no small value in mitigating the shortages of food which set in later; it had a further result in awakening a desire among many of the urban dwellers for a plot of land to cultivate. The Allotment movement thus stimulated is still active to-day,

difficult as it is to retain land near towns from the spread of building.

The Corn Production Act.—To assure the farmers of a return for the task imposed upon them the Corn Production Act (1917) was passed, which gave certain guarantees for the price of cereals for a term of six years. In effect these guarantees never were required, so rapidly did prices rise within a few months of the passing of the Act to a level then not contemplated. But other provisions of the Act touched the industry more closely. A minimum wage for agricultural labourers was fixed, and a machinery of Wages Boards was set up to determine what the minimum should be from year to year in each district. Again the stated minimum was nugatory, so rapidly did the situation develop, and the Wages Boards became organizations to fix the actual wage rate, not the minimum. Landowners were debarred from raising rents in so far as such increases could be ascribed to the guaranteed prices; indeed the whole Act was framed as a permanent policy of assisting agriculture as well as to meet the existing emergency. The farmer was to receive a certain guarantee of price that would encourage him to produce; the State assumed this burden because it was the general interest of the community to ensure production from and employment upon the land. If the farmer was thus secured the labourer in his turn must be assured of a living wage; the expenditure of the State was not to go wholly into the farmer's pocket. The landowner again was not to divert the benefit intended for the producers, as he might otherwise do on the fundamental economic basis that rent represents the difference between the earning power of that land and of land on the margin of cultivation. The Act was directed to maintain and extend the area of cultivation, and whatever its defects, defects that are inherent in all such schemes of bounties or protection (namely, that they cannot ensure a responsive effort on the part of the farmers nor avoid an unearned increment on land that was already profitable) it was the first coherent scheme that recognized the needs of all classes interested in the land.

Price Fixing.—The immediate interests of the farmers were, however, far more concerned with the course of prices. Early in 1917 definite shortages began to be manifest, attended by rapid upward rushes of price and speculation among dealers. The newly formed Ministry of Food was therefore forced to embark upon a course first of price fixing and then of rationing all the major articles of food. Such measures involved a very complete control of the whole machinery of distribution; prices had to be fixed for both consumer and producer, the middleman's allowances were determined, and the supplies had to be artificially directed to meet the requirements of each district. As far as farmers were concerned, two main difficulties had to be met by the Food Controller. He had to effect a compromise between the high prices necessary to stimulate production and the low prices required by the consumer, opposites that proved almost irreconcilable with regard to milk in the later years of Food Control. The fundamental problem of rationing was solved by leaving the consumption of bread uncontrolled and keeping its price down by a subsidy. Thus even the poorest could secure their main food supply, after which high prices might be allowed to check consumption of the supplementary articles of diet. The second difficulty lay in fixing the prices of much of the produce of the farmer on a reasonable parity, so that he would not be tempted to concentrate on the production of the most profitable. For example any cereal can be converted into milk or meat or eggs; butter or cheese might be more profitable than the raw milk. A shortage in cattle food was soon disclosed since so much of it had come from overseas while the carefully rationed ships' tonnage had to be reserved for essential human foodstuffs, soldiers and munition materials. Also the normal home production of cattle food was itself reduced because wheat was milled more deeply so as to produce 5 or 6% of poor offals instead of the 30% before the war; hence the situation had to be faced when it might be necessary to reduce greatly the animal stock. Actually the milk herd of the country was not appreciably reduced, but sheep declined by one and a half millions between 1916 and 1918, and the pig herd, nearly two and a half millions in 1914, had fallen to 1,700,000 in 1918.

It cannot be said that the numerous regulations imposed by the Food Ministry and the Board of Agriculture in the critical years 1917-19 were wholeheartedly observed. Many of them ran counter to the traditions of the farmer, who apart from any question of profit could always see his own reason for following his accustomed routine. Thus the campaign for ploughing up grassland, which was the main item in the Board of Agriculture's programme, met with much obstruction and a somewhat grudging performance. All the instincts of the farmer were against breaking up a good pasture which was producing some food when undisturbed, whereas the crop he would get from it was problematical. The argument that even a bad corn crop could do far more to feed the people than the meat or milk which could be derived from the grass, carried little weight with the farmer who was uncertain of his labour supply, who feared wireworm and weeds, who thought of the time when he would have to put the land back to grass. Few farmers again would withhold grain from stock when stock were so profitable and little or none of their accustomed feeding stuffs were to be had.

Increased Production.—During the latter part of 1917 and early 1918 the energy of the Food Production Department and its county committees found a real response, with the result that in 1918 as compared with 1916 the total arable land of the United Kingdom had been increased by 1,720,000 ac. and the land under crops by nearly three million acres, the increase in wheat being three-quarters of a million acres, in oats over one and a half million acres, and in potatoes nearly 400,000 acres. But the withdrawal of more men from the land for active service in the spring of 1918 and the disastrous harvest conditions that were unfortunately experienced, so intensified the opposition to compulsory ploughing that no further progress could be made, indeed there were nearly half a million acres less grain in 1919 than in 1918. Happily the war had come to an end in November, 1918, or the consequences of this revolt against the ploughing up of grassland might have been a food shortage of the sternest kind.

TABLE I.
CROPS AND STOCK IN ENGLAND AND WALES (000 omitted)

	1914.	1916.	1917.	1918.	1919.	1924.	1927.
	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.
Arable land . .	10,998	11,051	11,246	12,399	12,309	10,929	10,310
Wheat	1,807	1,912	1,918	2,557	2,221	1,545	1,636
Barley	1,505	1,332	1,460	1,501	1,510	1,314	1,051
Oats	1,930	2,085	2,259	2,780	2,564	2,037	1,748
Turnips and Swedes	1,045	932	969	909	981	831	716

Other Cattle . .	3,394	3,786	3,762	3,623	3,641	3,231	3,484
Sheep (total) .	17,260	17,951	17,170	16,475	15,124	14,843	17,070
Pigs (total) . .	2,481	2,168	1,919	1,697	1,798	3,228	2,687

At this stage, when the actual fighting was over but the crisis of food supplies still persisted, the temper of the farmers turned very strongly against control. They had become organized and by iteration of individual inconveniences every regulation became a general grievance. It is the evil of all price fixing that the producers are almost perforce driven to base their case upon the performance of their weakest members; hence follows either inordinate profits for the more efficient or restriction of supplies.

Effect of the War upon Farming.—The consequence of the war, which from the farmers' point of view may be regarded as persisting until near the end of 1920, for there was little relaxation in the operations of the food controller until then, was a great temporary prosperity for the farmers. Even though, checked by the regulations of the food controller, the British farmer always had to sell his wheat at less than the world price, that is, at less than foreign corn was being bought for distribution in the United Kingdom, and though the cost of labour and prices had risen to a high level and commodities rose also, rent had not varied and the balance was strongly in his favour. He had also enjoyed the benefit of the lag which affects all farming operations—that much

of the expenditure incurred in preparing a crop antedates the sale by many months; hence on a rising market some at least of the costs are incurred on a lower scale than the realization, this being particularly true of labour. While the largest sums of money were earned on farms growing potatoes and vegetables, probably the highest rate of profit was on the purely grazing farms selling sheep and wool, young stock and milk, and employing little labour. But the only men who really kept their profits were those who gave up their farms and sold their stock before the end of 1920.

The most immediate effect of these profits was a sharp rise in land values. During the period 1918-21 there were immense sales of agricultural land amounting on a conservative estimate to three million ac. in England and Wales. About one-eighth of the farming area of the country changed hands in these years at greatly enhanced values. Landowners were not able to raise rents though their disbursements for tithe, repairs and taxation had increased; farms being in demand, it was evident that they could treble or even quadruple their net incomes from land by selling it and investing the proceeds in Government Stocks. Tenants were anxious to retain their holdings but had to buy in order to do so. Consequently these years saw the creation on a fairly large scale of an owner-occupier class of farmer. Some of these men had already made money enough to pay for their farms or were able to do so while prices were high; they were comparatively safe when the crash in values came in 1921. The men who then found themselves in difficulties were those who had bought their farms on borrowed money and still carried the mortgage; still more those who had entered and stocked their farms in the period of high prices.

Considering the production of the country we have already seen that the advance in the arable and particularly in the corn area attained in 1918 was not maintained even in the years of high prices that persisted until 1921. All powers of dictating cultivation were abandoned at the close of the war. As regards live stock the size of the milk herd was maintained, though the beef herd suffered a small decline. The sheep flock of Great Britain, of England in particular, was greatly diminished; in England and Wales it stood at about seventeen and a half million at the beginning of the war, had fallen to sixteen and a half million in 1918 and reached its lowest point, 13,383,000 head in 1921, while analysis of the returns shows that the loss had fallen almost entirely upon the sheep of the arable counties. Arable sheep farming had always been a special British feature characteristic of the open country upon the chalk and the sands. There half the arable land used to be farmed with fodder crops—rye, winter barley, tares, rape, kale, turnips and swedes, which were sown so as to afford a succession of green crops upon which the sheep were closely penned in folds that were moved day by day on to fresh ground. In addition to their green food the sheep and lambs received a little hay and corn and cake to force them on for market at an early stage; the land received the benefit of the manure made from the food and the treading of the sheep. This system, the sheet anchor of the older light land farming, was unsuited to war and post-war conditions. The labour required, both for the fold and the growing of the fodder crops, was too expensive at the new rates of wage, the supplementary feeding stuffs were unobtainable, and prices tempted the farmer to sell all his flock and put the land into corn. Again fixed prices ignore quality; the arable sheep farmer could no longer realize the extra price he had been accustomed to obtain for his quickly-grown lambs. Consequently the great arable sheep areas in Hants, Wilts and similar counties lost up to 50% of their sheep and though numbers have been reviving of late years the restocking has been with grass breeds like the Cheviot-Border, Leicester half-breeds, Exmoors, Kerry Hills, etc., to the permanent loss of the Down breeds, like Hampshires, Oxford Downs and Southdowns.

The stock of pigs suffered great reductions with the shortage of feeding stuffs in 1917, 1918 and 1919. The herd which in England and Wales had remained for many years at about two million fell to 1,700,000 in 1918, but has since recovered rapidly to more than its previous level, reaching indeed three and a quarter million in

1923. The numbers of poultry followed much the same course as that of pigs and from the same causes, but the post-war development has been more marked with the rapid extension of the knowledge of skilled poultry management.

THE POST-WAR DEPRESSION

The course of agriculture after the war will be best appreciated by a study of prices. The following table shows the average prices of some of the chief items of agricultural produce for the cereal years (Sept.-Aug.) 1913-14 to 1926-27.

TABLE II.
AVERAGE PRICES FOR THE CEREAL YEARS (SEPT.-AUG.)
1914-15 TO 1926-27

Year.	Wheat per qr. of 480 lb.	Beef (*) per cwt.	Milk (†) per gal.	Wool (**) per lb.	Potatoes‡ per ton.
	s.	s.	d.	d.	s.
1914-15	49·8	72·5	9·8	18·5	77·0
1915-16	53·0	84·5	12·8	17·0	110·0
1916-17	74·3	110·0	15·3	18·9	207·5
1917-18	72·3	114·0	19·0	20·3	139·0
1918-19	72·8	124·5	24·0	35·8	164·5
1919-20	75·6	140·0	27·5	41·0	241·0
1920-21	84·7	148·5	25·0	9·8	199·5
1921-22	50·7	96·0	17·3	13·3	174·0
1922-23	42·5	88·0	15·5	16·8	71·5
1923-24	45·0	88·0	14·9	22·4	185·5
1924-25	53·6	88·0	15·0	15·9	187·0
1925-26	52·5	84·0	14·9	14·0	108·5
1926-27	51·1	76·0	14·3	15·9	143·0
Nov. 27§	45·0	65·0	16·0	18·5	120·0

§Approximate prices.

War prices were maintained until the spring of 1921, then they dropped by about one-third by the close of the year. The prime cause was the deflation of money in Great Britain and America which was then effected; the secondary causes were the abundant harvests in the vastly expanded area of cereals in the Americas, particularly in Canada, and the lack of purchasing power among the war-ruined population of Europe. Prices in Britain continued to fall until 1923, then tended to recover a little until the long-continued coal strike of 1926 produced a new fall which specially hit the class of farmers who had so far suffered least, namely, the producers of milk and meat. The situation has been aggravated by a succession of bad seasons since 1918, which of themselves would have hurt the position of farmers even in normal times. Bad growing seasons, wet harvests, foot and mouth disease, have been serious contributory factors in the ruinous condition in which British farming now finds itself. Deflation alone wrote off nearly half the capital farmers estimated they possessed in 1921, and though this did not really alter the position of men who had been farming continuously from before the war, it fell heavily upon those who had entered farming during the years of high prices or had mortgages out from the purchase of their farms.

Post-war Legislation.—The state of agriculture has not been without consideration and legislative action during the post-war period. War experiences had persuaded both Parliament and the general public that the maintenance of a prosperous agriculture was of some moment in the national policy. Even during the war a reconstruction committee under Lord Selborne had examined the question and drawn up a series of recommendations on which the Corn Production Act of 1917 had to some extent been based. But that Act, as already seen, had immediately become nugatory as far as guarantee of prices was concerned. As the outcome of a Royal Commission which sat in 1919 an Agriculture Act was passed in 1920, which accepted the main principles of the old Act by charging the State with the payment of subsidies on the acreage of wheat and oats grown, whenever the prices fell below the assessed costs of production. The county agricultural committees became statutory bodies endowed with powers to determine ten-

ancies in case of persistent bad cultivation or neglect, and even to enter upon the land and act themselves in cases of default. Wages boards were continued and tenants were given greater security of tenure by provisions which compelled the landlord to give compensation for disturbance equivalent to a year's or even up to four years' rent, unless the county agricultural committee would certify that the notice to quit was justified by the bad cultivation of the tenant. The Agriculture Act had, however, but a brief existence. It antedated by only a few months the break in prices of 1921, and it soon became evident that under the guarantees the State would be called upon to pay a very large sum

MEDIAEVAL METHODS OF AGRICULTURE

Reaping corn. From the Louterell Psalter, an illuminated manuscript of the early part of the 14th century. ("Vetusta Monumenta" vol. 6, pl. XXIII., fig. 3)

upon the acreage of wheat and oats grown. The basal figure had in fact been set much too high for oats, a crop which is mostly consumed upon the farm and which therefore does not greatly affect the income of the farmer. But no attempt was made to remedy this defect; the public cry for economy was so insistent that the Act itself was repealed in 1921 within 10 months of its passing, in spite of all the promises set out in the Act that four years' notice would be given before the guarantees were withdrawn. The repeal coincided with the very situation the Act was designed to obviate, a wholesale break in prices brought about by causes beyond the control of the farmer, brought about indeed in this case by the deliberate deflation policy of the Government. With the guarantees the wages board disappeared and though conciliation committees were set up in most counties, the average weekly wage dropped from 42s. in September, 1921, to less than 28s. before the end of 1922. The repeal of the Agriculture Act put an end to all ideas for a national constructive policy for agriculture, the industry must henceforward sink or swim by its own powers and be guided by its own lights. The action was part of the pessimism of the time, of the war weariness that shirks any sustained effort and doubts the value of any planning for the future. Bitterly as it was resented by the farmers, who thereby lost all confidence not only in governments but in agriculture itself, it was angrily acquiesced in, because they got rid of their two greatest bugbears—the shadow of control of farming and wages boards. The resentment generated by ploughing-up orders given in 1918 and other interferences consequent upon the orders of the food controller, had been worked up to an intensity out of all proportion to the actual hardship that had been inflicted, and farmers generally were prepared to purchase freedom at any cost. A very large proportion of them indeed grew little wheat or oats and were anxious to grow less in the difficult state of arable farming. So the farmers' representatives, while protesting, accepted the situation; they saved those sections of the Act that gave them compensation from disturbance (provisions which have injured the land-owners and are in many respects a hindrance to the improvement of farming) and they obtained as a slight recognition of the sacrifice imposed upon them the allocation of a million pounds to the extension of agricultural research and education.

Since that period the National Farmers' Union, in which is concentrated the political opinion of the farming community, has been averse to any further interference of the State with agriculture. The distressed state of the industry gave rise to a further enquiry in 1923—the Agricultural Tribunal, consisting of three economists not directly connected with agriculture, who produced an illuminating survey of the subject early in 1924. The main

recommendation of this report, a subsidy upon arable land with further assistance to the growth of wheat, received little support from the farmers' organizations and was never adopted by the government of the day. It also recommended the re-establishment of the wages boards and this was given effect to in 1924. The only other legislative measures calling for some comment were an Act in 1922 which disposed of a long-standing controversy by permitting the admission of Canadian store cattle into Great Britain, and the Agricultural Credit Act of 1923 which gave some relief in the shape of cheap mortgages to farmers who had purchased their holdings during the operation of the Corn Production and Agriculture Acts. Again the British Sugar (Subsidy) Act of 1925 provided a very ample scale of subsidies on sugar produced in Britain, for a period of 10 years, in order to encourage the establishment of a sugar beet industry in this country.

Wages and Prices.—The difficulties of agriculture at the end of 1927, enhanced by the bad harvest of the year, may be apprehended from a study of the course of prices, the cost of living and the weekly rate of wages from the beginning of the war down to the present time. The cost of living, being based on the general cost of commodities, is some index of the cost of the farmer's necessary purchases; the rate of wages measures the largest item in his expenditure, or from one-quarter to one-third of the total

costs of production on arable land. The fundamental disproportion is seen—that while in October, 1927, the price of farming products only stands at 40% above the pre-war index, commodities are 67% higher and labour, the largest item of the farmer's expenditure, is 76% higher.

The low agricultural prices are not due to over-production, for as far as can be estimated the gross output from the land of the world, actually lower in some items, has not kept pace with the growth of population since 1914 (*see later, section World Agriculture*). That this shortage has not resulted in higher prices is due to the destruction of the purchasing power of so many of the countries of the world, through war and revolution and the depression in industries. The efforts that so many states are making towards a deflation of their currency is regarded by many economists as the immediately operative factor, depressing prices for all producers and destroying the confidence upon which industrial activity depends.

The other element in the equation—the relatively high cost of labour—cannot be met in England by a reduction in the wage rate, which in agriculture is already below that prevailing in other industries. Indeed, bad as is the state of trade, men are leaving farming for any other occupation that offers; many farmers are complaining of the shortage of labour, and in certain cases where profits are assured, as in sugar-beet growing, labour from Ireland is being imported. Any local call for men immediately draws agricultural labourers from their following and when any general

revival of industry takes place the land is likely to lose most of its active and able-bodied men. Thus if no other change supervenes, farming, except for those special businesses that can command a sheltered or a luxury market, will be reduced to a species of ranching with a minimum of labour. There is one alternative—a sustained effort to make labour more effective, on the one hand by better organization, by the use of machinery and the elimination of wasted effort, and on the other by careful training to increase the skill of the individual. Much of what was called "good" farming before the war was still dealing with labour on a mid-19th century basis of wages, and though operations had been cheapened after the fall of prices of the eighties and the nineties, there has been no radical reconsideration of methods such as is called for by the modern relation of wages to the prices of agricultural produce. This is the big problem before British agriculture—the revision of all its traditions of husbandry, and it requires the co-operation of the investigators, both scientific and economic, with the study by individual farmers of the conditions imposed by their own farm and particular business. The investigators may supply stimulus and guidance, but the main effort will have to be exerted by the farmers themselves, for the problem is one of management and practice, demanding a consideration of the technique of farming and the arts of leadership and management that has not been forthcoming for the last two generations. Some encouragement, some renewal of confidence may come from increasing prices, for the withdrawal of men from the land because of the superior rewards in other occupations is not confined to Britain but is common to all countries. It is affecting the peasant as well as the wage-earning labourer, it is manifest in the United States as in France. Its effect upon output must become manifest, and as the world's population still continues to grow, scarcities will be declared, and whether by compulsion or by choice, farmers will have to intensify their production from the land.

AGRICULTURAL CO-OPERATION

The obvious advantages that can be obtained by buying and selling on a wholesale scale and the great success attending co-operative effort among farmers abroad, particularly in Denmark, has for many years caused agricultural co-operation (*see Co-operation*) to be pressed upon the British farmer. The work of propaganda and advice was undertaken by the Agricultural Organization Society, which was founded on the model of the successful Irish Society initiated by Sir Horace Plunkett. The A.O.S. was a voluntary organization supported by subscriptions from its affiliated societies, but it enjoyed a considerable amount of subvention from the Development Fund from 1910 to its demise in 1924. The earlier efforts at co-operation chiefly aimed at the formation of purchase societies to supply the farmers' requirements for fertilizers, feeding stuffs and other materials. Though many of these ventures had but a brief existence some have become strong trading corporations, such as the Eastern Counties Farmers' Co-operative Society at Ipswich. A wholesale society, launched during the war with the object of bulking the purchases of individual societies, came to disaster. Little progress was made with societies for the sale of farmers' produce, though a number of egg-collecting depôts were and still are flourishing. Dairy societies had a somewhat chequered existence; in some cases as soon as they attained local success they attracted the attention of one of the big dairy firms and after a period of fierce competition either succumbed or were bought out. Eventually the Agricultural Organization Society, despite all the devoted work given to it and the subventions it had enjoyed, found it necessary to dissolve. It had never received any wide measure of support from farmers, and as the National Farmers' Union had become the representative organization of the farmers of England and Wales and was prepared to take over the care of co-operative action amongst its members, the old society gave way to the National Farmers' Union. At the same time the Government under the Agricultural Credits Act made provision for loans to Agricultural Co-operative Societies on the basis of a loan of 20s. for each 20s. share taken up by members, of which

no more than 5s. need be initially called up. The history of these latter ventures has not been altogether encouraging. At the same time there was a movement for the setting up of co-operative bacon factories on Scandinavian models. Seven such societies were started, of which only four are working to-day. Two active wool-selling agencies have been established, one in the south-east and one in the northern counties, both of which are steadily progressing. In 1925 on the termination of the hop control, a wartime organization, a new voluntary organization was formed to continue the collective sale of hops and has succeeded in enlisting some 90% of the hop-growers of the country. While other examples could also be named, speaking generally, agricultural co-operation has made but little progress among the farmers of England.

The reasons are not far to seek. In the first place the larger English farmers make their purchases on a big enough scale to secure terms comparable with those offered by the co-operative society. When such men joined a purchasing society they were apt to use it merely to beat down the terms offered by their merchants. The smaller farmers followed the lead of the big men or were unable to forgo the credit they obtained from the merchants. Again the firms dealing in agricultural necessities were very firmly entrenched in Great Britain; many of them were bigger and more efficient than a newly-started co-operative society could be, and having capital behind them did not shrink from competition. They had the great advantage too of being able to offer credit, and their agents being generally drawn from the farmer class had friends and connections among the men with whom they wanted to do business.

Societies for the sale of farmers' produce have an even more difficult task. Trade rivalry is equally strong; the customary markets are close at hand and farmers are loath to forgo their individuality or renounce the chance of a temporary rise of prices. Co-operative selling involves working to contract and the production and regular delivery of a standardized article. The bacon factories failed largely because they could not ensure a regular supply, the farmers diverting their pigs to other channels when prices rose. Firm contracts to deliver regularly were refused by the producers or could not be enforced. Milk societies would be compelled by their members to give a price too high for successful working because a competing trader with a long view would offer prices above the economic parity. Certain ventures failed also from embarking upon a manufacturing process, like bacon curing, which requires a considerable degree of technical skill, and the inability of the society to pay a competent manager or else to find one before its resources went.

The existence of a near-by market is the great obstacle to agricultural co-operation for the sale of produce. Nearly all the examples that are so freely quoted of the success of farmers' organizations—the bacon factories of Denmark or the fruit selling associations of California—rest upon the fact that only an export trade is available and that farmers cannot engage individually in such a trade. They are driven to organize because the alternative is the control of a wholesale trader who cuts the producers' returns to the minimum that will keep them in business. For these and other reasons the true co-operative spirit has been lacking, and British farmers have not shown that loyalty to the principle of combination which would induce members to stick to their society even at the cost of some loss to themselves. When there is an old-established market at hand it is almost impossible for a co-operative business to give the farmer better returns at once. Psychologically, too, defaulters and men who stand outside a combine have a powerful disintegrating influence upon it. They share in all the benefits if the combine succeeds in raising the general level of price, they take no risks and get paid at once, while members may be waiting for a portion of their returns because the society has only succeeded in raising prices by withholding part of the crop from the market. The "outsiders" would not be human if they did not boast about their advantages, and English farmers are as yet too easy-going and too much merged in the general community to counter with a social boycott. Similar occurrences in certain of the British

Dominions have resulted in legislation to force recalcitrants into any combination which has secured the adhesion of three-quarters or four-fifths of the producers; but such procedure is quite alien to the English farmers' declared policy of "No Control." Yet the acceptance of voluntary control is the essence of co-operative organization, and by virtually compelling farmers to produce the article wanted by the market, rather than that which they fancy, exerts a powerful educational influence. On the other hand if he does not accept the voluntary control of his own organizations the British farmer is likely to drift into subjection to the much less sympathetic control of big businesses which will make of him a tied producer.

Thus the prospects of agricultural co-operation do not appear bright, though the situation is not without hope; a sense of the necessity for combination is growing. Nothing can be gained by preaching co-operation at large, but little by little particular instances are making good, especially where the association only attempts to sell and not to manufacture the raw material provided by the farmer. An alliance may be possible with the great co-operative organizations among consumers, which indeed have hitherto been spending their efforts in organizing foreign rather than home producers. But it is only by combination of some sort, from within or from without, that British farmers can hope to retain a remunerative share of the best of all agricultural markets—that of Great Britain. See AGRICULTURAL CO-OPERATION.

BRITISH FARMING SYSTEMS

British farming is characteristically an affair of small capitalist businesses employing paid labour. The following table (Table IV.) of the holdings in England and Wales shows the apportionment of such holdings with respect to their size.

TABLE IV.
NUMBER OF HOLDINGS BY SIZE, ENGLAND AND WALES, 1924
(Excluding holdings of less than 5ac.)

Area in acres.	Number of holdings.	Total acreage.	
5-20 .	111,934	1,264,217	252,252 farms, comprising 8,309,843ac. of less than 100-ac. units.
20-50 .	79,537	2,691,131	
50-100 .	60,781	4,414,495	
100-150 .	31,930	3,924,450	80,272 farms, comprising 17,266,059ac., of more than 100-ac. units.
150-300 .	35,485	7,420,533	
300 .	12,857	5,921,076	

Characteristically, too, the farms are tenancies held under yearly agreements, though the tenant is largely protected from disturbance by the Agricultural Act. The landowner provides the permanent equipment of the farm—buildings, gates and fencing, water supply, drainage. The landowner also is responsible for repairs to the fabric, but minor improvements of which he will remain possessed are generally carried out on the basis of the landowner finding materials—timber for fencing, bricks, stone, gates, drain tiles, seeds for permanent pasture, etc., and the tenant finding the labour. The landowner's capital has been estimated to amount on the average to £31 per acre, the tenants to £12-£15 per acre, and the average rent to 31s. per acre. Under such a system the entry upon and leaving of a farm, at whatever date, necessitates a considerable adjustment of account between landlord and tenant, since the farm must be left as a going concern. These adjustments were formerly regulated entirely by custom and though they are now governed by the various Agricultural Holdings Acts (consolidated in 1923), custom is recognized and still plays a large part. The basis of the Act is that the outgoing tenant is entitled to compensation from the landowner for all improvements he has effected, the amount of compensation being determined by the value of the improvement to the incoming tenant. For certain types of permanent improvement, e.g., buildings, plantations of fruit trees, the tenant is not entitled to compensation unless the consent of the landlord has previously been obtained. The purpose of this exclusion is to prevent the tenant from committing the landowner to payment for an improvement which the latter might not be able to realize. For example the

improvement effected by planting land with fruit or hops might be valued as high as £100 an acre, with embarrassment to the landowner if he had to pay out this sum on the determination of the tenancy without any assurance of being able to find a tenant willing to pay an adequate rent for it. An exception is made in the case of holdings let as market gardens. Here general legislative sanction has been given to what was known as the "Evesham custom." The tenant possesses the right of free sale of the improvements he has made, e.g., beds of asparagus, fruit plantations, etc., but must find the purchaser, the landowner being obliged to accept the tenant proposed by the outgoing tenant, who has made his own bargain for the improvement with the new tenant.

In ordinary cases the negotiations with regard to improvements proceed between the outgoing and the incoming tenant, in whose agreement with the landowner is a clause that he shall pay whatever compensation is due to the outgoing tenant. Each tenant appoints a valuer who between them prepare an agreed valuation of the tenant right, there being provision for an arbitrator in cases of dispute. The account includes the cost of cultivations carried out before leaving the tenancy standing crops and manurial residues whether of fertilizers applied or purchased feeding stuffs consumed during the latter years of the tenancy. But as farms are vacated at different dates in different parts of the country, though most commonly at Michaelmas or Lady Day, custom still plays a large part in determining both what things are the subjects of compensation and the basis of assessment.

Tenancy.—The British tenancy system possesses many advantages. The handicap that farming is under as compared with other industries lies in the large amount of fixed capital involved in comparison with turnover and in the lag that exists between expenditure and returns. For the farmer who has to own his farm this implies a considerable degree of credit, and in foreign countries it has generally been found necessary to give some State support to landbanks or other long term credit organizations which will take the burden of the capital outlay on land and buildings. The short term credits required for the conduct of the business proper are supplied by co-operative associations or the banks. Otherwise mortgages rule and mortgages have universally proved destructive to the farmers whenever a run of bad seasons occurs. In Britain the landowner has supplied the cheap capital the industry requires for its permanent equipment, and the banking system so far pervades the community that it can furnish a not unreasonable proportion of the working capital the farmer should have. Even so the farmer would have to work upon a much smaller proportion of borrowed capital than prevails in other business, and in practice in Britain the farmer resorts to a dangerous extent to the tradespeople with whom he deals. The merchants who sell to him his requirements in manures and cakes and buy from him his corn and hay, and the auctioneers through whose hands pass the store cattle he buys and the finished cattle and sheep he has to sell, provide to a very large extent the financial backing of the industry. This custom obviously limits the power of the farmer to buy and sell in the best market, and it has been proposed by legalizing the creation of chattel mortgages to enable the banks to accord greater credit facilities. The farmer could then assign his livestock or his standing crops as security for advances.

The tenancy system undoubtedly assisted in the development of British farming in the 19th century, though it produced a certain number of cases of oppression when the power of the landowner to turn out a tenant for causes unconnected with farming remained unrestricted. The condition, however, of success in a tenancy system is the possession by the owner of a real knowledge of, and interest in, the conditions of farming. He (or, in the case of large estates or other interests, his agent) must have considerable technical knowledge, if he is to be a working element of the system, the adviser and leader of his tenants. The declining interest of landowners in agriculture and the inadequate training of so many of the agents employed by them have been a main cause of the weakness that the tenancy system has latterly displayed and its hampering effect upon enterprise and innovation among the farmers. Many people, therefore, aiming at a return

to a system of occupying ownerships plead the necessity of freedom for the cultivator and the stimulus of the "magic of property"; though it will be within the experience of those who have had occasion to survey the countryside in detail that even if some of the best, so also many of the worst, managed farms are the property of their occupiers. Further in a modern state no ownership system persists; minors, females or men with other interests inherit, and the new owners prefer to let rather than to sell. For these reasons it has been argued that the welfare of the industry demands the state ownership of all agricultural land and a stricter exercise of the continuing owner's interest in good farming.

Small Holdings.—Other observers who were impressed by the straits of wage-paying farming, even at the low rates for agricultural labour, have sought a solution in a break up of the larger holdings characteristic of British farming and a return to the peasant system of family farms which are customary in most parts of the world. Even in the worst of the depression flourishing colonies of small holders could be found in many parts of the country, and the creation of small holdings has been attended by an increase in the production from the soil. For instance in the Vale of Evesham grass farms on clay land which were indifferently grazed, and yielded but a poor return of milk and store stock, became intensively cultivated for asparagus, plums and other vegetables and fruit; where there had been perhaps one man employed per hundred acres, the small holders would make a thrifty living on fifteen acres of the new cultivation. Consideration of such cases led to the Small Holdings Act of 1908 (see *ante*, *British Farming Systems*) and to a widespread demand for a general policy of dividing up the land. It is doubtful, however, whether the admitted success of small holdings is a sufficient basis to justify their general application to British conditions. The success of small holdings depends upon two factors. The small holder, being his own master, works harder and more intelligently and for longer hours than the paid labourer; he also throws in the work of his family, often of considerable amount. Large farmers would agree that if they could get from their labourers the quality of work put in by the small holder they could pay wages even higher than the returns obtained by the small holder. Small holders, therefore, are concerned with the production of those things in which manual labour bulks largely, but also they must engage in a branch of the industry that has a rising market, and preferably one that is naturally protected. With their ears to the ground they have been quick to seize upon small things that the large farmer neglects. Milk, potatoes, vegetables, fruit and poultry, and occasionally pigs, have been the produce upon which the small holders have depended. They rarely touch the main lines of farming—corn, beef, or sheep and even with milk they often make their profit by combining retailing with production. Thus the opportunities for small holding are limited and the markets they cater for are easily overstocked although as regards milk and vegetables they have reaped the advantage of a demand that has been steadily rising for years. As a rule small holders require good land and can make little use of the great areas of the chalk and clay soils.

While it is generally agreed that small holdings are unsuited to the production of corn or cattle and sheep breeding it is argued that even these branches of agriculture could be pursued if they were organized for the co-operative use of machinery, pedigree sires, etc. But this is only equivalent to saying that small holding farming could be successful if imperfectly and by agreement it adopted the methods of large farming. Co-operative farming has not been realized and the mark of the small holder is his independence; as a rule he has only become united with co-operative selling societies when he has been under the necessity of working for an export market. Nor is there necessarily any greater production from land under small holdings; in the instance quoted above the increases are due to a change in system introduced by the small holder. But the large-scale fruit grower or market gardener or milk farmer will produce more per acre and that of better quality than the small holder working single-handed. Organization and the command of capital in the large businesses tell even against the individual attention which is the asset of the

small holder; spraying is more suitably undertaken on an extensive scale, clean milk more often comes from the large herds. The greater production per acre of the small holder is often a consequence of the more intensive farming which he is forced to adopt but which would be uneconomic if the labour had to be paid for. There are thus two cardinal difficulties attending upon a revival of a peasant system of farming in Britain, one economic, the other social. The economic drawback is the higher capital outlay involved; the creation of a colony of small holdings necessitating expenditure on buildings, roads, fencing, water supply, etc., that is much greater than would be required on a farm of equal area and engaged in the same type of farming. But it is not germane to quote the excessive cost of the small holdings set up after the war, which reached £2,000 and upwards per holding, because at that time no farm, large or small, could have been equipped on bare land so as to produce an economic rent. The old peasant holdings inherit in their buildings and equipment, the results of the gradual unpaid labour of many generations, and when the holding is sold this accumulated capital is counted cheap, because the price is based upon the farm's earning capacity, not upon what it would cost to reproduce it: hence the prime economic difficulty of building up small holdings *de novo*. The second question is whether small holdings can persist on any large scale under modern conditions. Depending on the basis of the occupier giving his labour cheaply as measured in terms of hours and wage rates, the total cash returns from a small holding are often little or no better than the wages of the agricultural labourer and still less than those of the industrial worker. A certain number of men are always prepared to give this price for their independence and for the chance of getting on, and upon this fact depends the social value, even the necessity, of small holdings. But it cannot be expected that a whole class of the community will permanently consent to lower wages and longer hours. Looking back at the history of British farming the merger of the smaller into the larger farms has always been going on. In other countries peasant farming has persisted longer because of the slower development of the industries, though even in France to-day the peasant is being attracted from the land, and in America the younger generation looks askance at continuing the family farm. It is in China, Japan and India that the sheer pressure of population maintains the one man farmer at a standard of living barely above the starvation level. Some small holdings are a necessity as a social safety valve; but a general return to small holdings would not solve the problem of increased food production. Farming is an industry like any other and a return to small holdings would be as much a retrograde step as would be a return to hand weaving. Nor is the argument valid that the State would gain by having more men employed upon the land. If extra men are employed on the land because the production has been intensified there is a gain, but if the extra labour has only to make up for an inefficient method there is loss. To prohibit machinery and return to spade labour would ensure the greatest number of men upon the land but the community would lose thereby. That community is the richer which employs the smaller proportion of persons in the production of its necessary food, leaving thereby a greater number free for the production of clothes, houses, etc., and other elements constituting wealth.

Industrialized Farming.—It is obvious that on the large farm very considerable economies of working can be effected, especially from the use of machinery. The cheapening of costs of production depends upon making manual labour more effective. Modern power cultivators are likely to be large in order to secure that speed and depth of working proper to their work; they therefore require large fields to save turning about and only broad acres defray their heavy overhead cost. Farming is no exception to other industries in that large scale working by its powers of organization and concentration of effort can obtain better work done at a lower cost. The improvement of live stock by breeding and selection is only possible with numbers upon which to work. Buying and selling is better done on a large scale, however much the small holder may be able to obviate his weakness by co-operation. Large scale enterprise can employ those methods of costing

and recording upon which good management is based. In his technical methods the small holder must work by tradition; he cannot afford to experiment and is therefore slower to accept new ideas. Furthermore the land still requires considerable capital expenditure if it is to be put to its best use; and drainage, the straightening of boundaries, and similar wholesale improvements are not practicable except on a large tract of land. It seems inevitable that as intensified production becomes imperative to provide food for a growing population it can only be obtained by large scale industrialized working. Two conditions, however, must be fulfilled before large scale farming can be attempted with confidence. First of all a new art of management must be evolved, based upon systematic cost accounting and a critical knowledge of average standard costs. Good farming has hitherto been very much a personal affair depending upon the experience, intuition and determination of the individual. Industrialized farming will always require the qualities of the old farmer—his eye and energy; but it also calls for more calculated management even though farming cannot be standardized like other industries. The other condition of success is the formation of a corps of workers trained for their job and rewarded accordingly. The old type of agricultural labourer was a highly skilled man; much of the work of farming is now being done by men who have been prevented by some defect from entering other walks of life, or by youths who have been left to learn their craft haphazard. Efficiency demands efficient men, for however much machinery may be employed a farm cannot be supervised like a factory. But if the future of agricultural production lies with industrial farming, a bigger unit will be required than the present average British holding. Successful as was the farm of 200–500 ac. as a first step towards intensive production, it has become an uneconomic unit to-day; it is too small to take full advantage of machinery, is still retail in its buying and selling and demands too large a proportion of its turnover for management. With an average ratio of six labourers to one farmer on English farms, the business is insufficient adequately to pay one man solely engaged in management, and even units of 500 ac. are not large enough. The proper unit is probably something of the order of 5,000 ac., with some hierarchy of managers and under managers into which young men who have been trained for the work could enter in subordinate positions. But it is also one of the handicaps of the present system of British farming that its management is too rarely recruited from school or college as other businesses are. The possession of capital is more often the condition of entry and too often is regarded as dispensing with the need for any technical training; but the industry would be the gainer from a greater leaven of men who began on a more educated plane.

World Agriculture.—The depression under which agriculture is now labouring would seem, however, to offer little chance of a reorganization of the industry along industrial lines, there being nothing to tempt the large capitalists to take up food production. This depression is felt in all countries and, as the Economic Conference at Geneva in 1927 indicated, it is the outcome of the deficient purchasing power of Europe and of China due to industrial depression. It was perhaps initiated by the deflation policy of the leading States, because it is evident that the low prices are not due to overproduction in the usual sense of the word.

If we exclude from consideration Asia and tropical Africa, as being both self-contained in the matter of food, the population of the rest of the world, constituting roughly the countries inhabited by the white races of mankind, increased between 1913 and 1926 by approximately 50 millions, or $7\frac{1}{2}\%$. The corresponding increase in the area of cultivated land is susceptible of even less accurate estimation, but according to the best figures available is about 36 million hectares. Meantime, however, agriculture had not been intensified, rather the reverse, and on the basis of current farming one hectare of land ($2\frac{1}{2}$ ac.) is required to produce the food and other agricultural materials consumed by one unit of population. On this showing the increased food production since 1913 has not kept pace with the growth of population. Considering again the countries making returns to the International Institute of Agriculture, the wheat

acreage has increased in the same period from 109 to 119 million hectares, the production from 1,029 to 1,139 million quintals, i.e., nearly 11%. But part of this increase in wheat has been purchased at the cost of other crops. In the countries other than Asia and Africa the four chief cereals for human consumption, wheat, rye, barley and maize, taken together, have only increased in area by 4% and in production by 5%. Food animals have increased, cattle by 12%, sheep by 2%, while pigs have declined by 4%, from which an increase of 8% in the meat production may be estimated. These figures lead to the conclusion that latterly the expansion of world food production has not been keeping pace with the growth of world population, even taking account of the relative checks imposed by the war and by its consequences. The low

prices result from the deficient purchasing power of the larger population and from the fact that the greater part of the food production of the world is carried on by peasant farmers. This method of farming can neither alter its production in response to a lower demand nor combine to maintain prices. The men who are engaged in it accept the bad times because in the main no alternative is open to them, and by their capacity to endure hardships and yet persist in production at the low prices prevailing, they ruin the capitalist farmers who have to pay wages. But there are signs that the indifferent returns of peasant farming as compared with wage earning in the industries is beginning to tell

MEDIAEVAL HUSBANDRY

Going to the mill. From the Louterell Psalter, an illuminated ms. of the early 14th century. ("Vetusta Monumenta")

in the withdrawal of men from the land. It is clearly happening in the United States and in France, where may be seen in progress the movement that characterized England in the latter part of the 18th century. Peasant farming does not persist when industry and commerce come near and display their openings to the farmer. Moreover the opportunities for creating new peasant communities of farmers have become smaller; great stretches of unoccupied fertile land in temperate climates, such as were settled in the 19th century and provided food for the then unprecedented growth of population, have diminished. The demand for food and other raw materials produced from the land must soon be felt by the still growing population, and any return of industrial prosperity is likely to be followed by a sudden upward rush of prices because there is no margin of overproduction and accumulated stocks behind the present low prices. Production adequate to meet the real needs of the existing population cannot be met by extending the cultivated area but will require an intensification of farming on the land now available. Intensification will only be prompted by better prices and will then best be realized by large scale farming on industrial lines.

IN THE UNITED STATES

Canada and the United States are one agricultural unit. They produce more than one-fourth of the world's wheat supply, nearly three-fourths of the corn and more than one-third of the oats. They produce nearly one-third of the total grain supply, including rice. The United States is the most important food-producing area under one government. There are no trade barriers within the area. The population is fairly homogeneous and highly prosperous. This combination of circumstances provides the basis for a highly developed agriculture. It produces one-half of the world's cotton, two-thirds of the corn, one-fourth of the oats, one-fifth of the wheat crop and has about one-fourth of the hogs and one-tenth of the cattle.

Population.—According to estimates of the bureau of the census, over one-half of the white population of the United States came from the British Isles and seven-eighths from northwestern Europe (Table I.). It is often stated that the American population

TABLE I. *Estimated Population in the United States in 1920, by Country of Origin**

	Number
Great Britain and Northern Ireland	39,200,000
Germany	14,800,000

is a mixture of many races, but the population is as homogeneous racially as most of the countries of north-western Europe. The immigrants from southern and eastern Europe have tended to remain in cities, so that the farm population is practically all from north-western Europe, except the negroes in the cotton belt. The white population increasingly uses power and machinery in farming. In 1880, 44.4% of the population was engaged in agri-

1920	10,953,158	30,661,090	26.3

*Data for 1880-1900 were taken from the *Thirteenth Census of the United States*, 1910, vol. iv., p. 41; and for 1910 and 1920, from the *Fourteenth Census of the United States*, 1920, vol. iv., p. 34.

culture, and 40 years later, 26.3% (Table II.). The production per worker is so large that great quantities of cotton, grain and meat are available for export. In France, about 41% of the population is engaged in agriculture, but only a small quantity of agricultural products is available for export.

Settlement of the United States.—The public domain of the United States was acquired by cession, purchase and conquest. The first acquisition took place in 1781 and the last in 1853. From 1781 to 1802, the various States ceded to the United States 268,000,000 ac. (Table III.). New York State was the first to part with its lands and Georgia the last. The Louisiana purchase,

in 1803, whereby the United States obtained legal possession of 433,000,000ac. for \$27,000,000, was the greatest acquisition that the country has ever made. From this area most of the country's surplus food is produced. By the purchase of Florida in 1819, the nation obtained control of 32,000,000ac., at a cost of \$6,000,000. The annexation of Texas added 71,000,000ac., at a

For the Mexican territory of 325,000,000ac., the United States paid to Mexico \$15,000,000. In 1853, Mexico ceded to the United States 15,000,000ac. costing \$10,000,000. This was known as the Gadsden purchase.

Total	1,397,000,000

*B. H. Hibbard, *A History of the Public Land Policies*, 1924, p. 570.

When the national Government was formed, it was heavily in debt and public lands were sold in order to derive necessary revenue. Later the land policy was primarily concerned with settlement. More land was disposed of through homestead and timber claims than by any other single means. Cash sales were second in importance. Large areas were given to the railroads in order to encourage the development of the country; also to public schools and other educational institutions. The area still remaining in the public domain is mostly forests or arid grazing land.

*B. H. Hibbard, *A History of the Public Land Policies*, pp. 100, 103, 106, 113-115, 1924.

The data in Table V. indicate that there were five distinct periods of settlement, the first one between 1810-19. The period of depression following the War of 1812 checked settlement.

Another wave of active settlement occurred between 1830-39. More land was settled in this decade than in any other decade. Another active period occurred between 1850-59. This carried settlement into eastern Kansas. The next period of striking activity was between 1880-89. In this period, settlement occurred over most of the remaining territory, but much of the poorer land was left in Government ownership. The land disposed of between 1900-19 was mostly arid land that previously had been considered of little value.

Number and Size of Farms.—Since the first settlement, there had been a steady increase in the number of farms until 1920. The severe agricultural depression which began in that year resulted in a decrease in the number of farms (Table VI.). The number of farms of each size is shown in Table VII. The number of

*Fourteenth Census of the United States, 1920, vol. v., p. 65.

small farms and farm homes of less than 50ac. is increasing. These farms increased from 29% in 1880 to 38% in 1925. There has been a corresponding decrease in the percentage of larger farms. While 38% of the farms were less than 50ac., these farms included only 6% of the total land in farms. Only 3.3% of the farms had 500ac. or more, but these farms included 34% of the total land. Many of these farms were in arid regions or in regions where the land is not adapted to intensive farming; therefore these large farms included only 17% of the area of improved farm-land. The average size of farms in 1925 was 145 acres. Most of the country was settled under a policy of developing family farms. The data on the size of farms indicate the success of

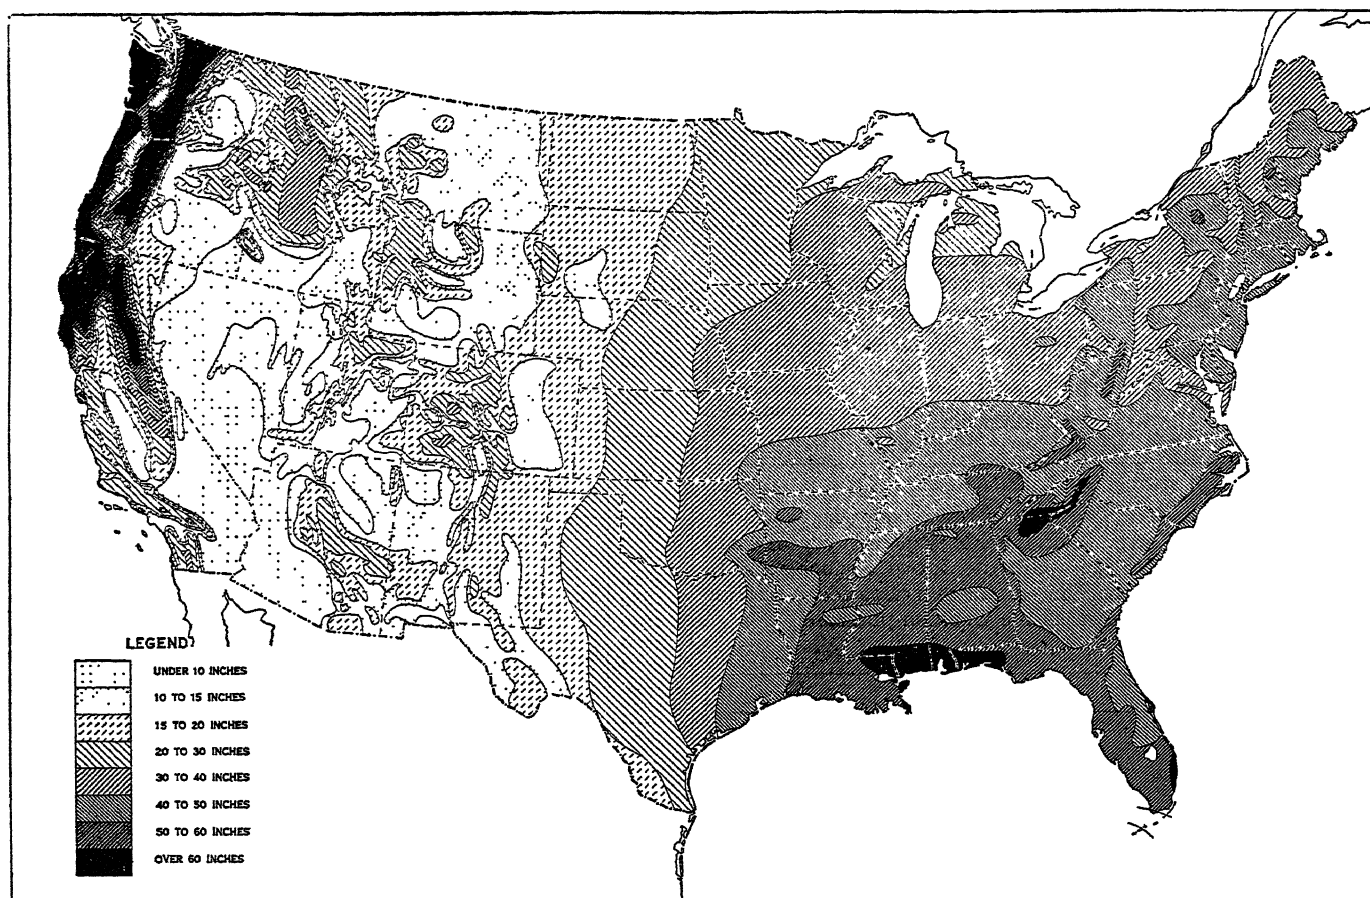

FIG. 1.—ANNUAL RAINFALL IN THE UNITED STATES. ABOUT TWO-FIFTHS OF THE COUNTRY IS SEMI ARID

this policy. There are very few farms that are too large to be handled by the farm family with a small amount of hired labour.

Uses of Land.—19% of the land area of the United States is in harvested crops; 12% in humid pasture; 12% in forests and cut-over land, a part of which is pastured; and 31% in arid pasture. The original forest area has been estimated at 822,000,000 acres. Nearly 60% of this is still in forests or cut-over land. Of the land in farms other than farm wood-lots, somewhat less than one-half was once in forests and over half was natural grass land. Additional crop land will be obtained by clearing forest lands and by use of pasture lands. The pasture land is the most available source

TABLE IX. *Utilization of the Land Area of the United States, 1919**

	Acres
Crops harvested	365,000,000
Humid pasture	231,000,000
Arid pasture	587,000,000
Forest, including cut-over and burned-over land, pastured	237,000,000
Forest, including cut-over and burned-over land, not pastured	246,000,000
Farm land not in harvested crops, pasture or forest	115,000,000
Urban, desert, marsh, roads and railroads	122,000,000
Total land area	1,903,000,000

*U.S. Department of Agriculture *Yearbook*, 1923, p. 416.

of additional crop land. The largest area of readily available good crop land was the natural grass land of the Middle West, extending to about the rooth meridian. West of this there are large areas of arid and semi-arid land, much of which has now come into use, but which requires economical methods of farming and particular care in the conservation of moisture.

The period of rapid settlement following the Civil War resulted in the occupation of most of the good land as far west as the rooth meridian. This land was so easily prepared for crops that a remarkable increase in production occurred between 1880-1900.

Topography.—The topography of the United States is shown in fig. 2. There are three mountainous areas: one in the east, one in the west and the Ozark mountains in the south-central part. About one-half of the area is mountainous. Much of this is covered with forests. The primary agricultural area is the central basin. Most of it is less than 1,500ft. in elevation. Along the

FIG. 2.—TOPOGRAPHY OF THE UNITED STATES

There are three mountain areas, one on each coast and one in the South Central part. Most of the crops are grown in the level areas and in the mountain valleys

coasts and between the mountains, there are many smaller areas that are highly developed agriculturally.

Rainfall.—The rainfall of the United States is shown in fig. 1. The western mountain range causes heavy precipitation along the coast, but makes most of the western two-fifths of the country arid. The rainfall of the central basin comes largely from the Gulf of Mexico. It decreases northward from the gulf. Rainfall is carried a short distance west from the Gulf of Mexico, but decreases rapidly in that direction. The boundary line between the

humid and semi-arid areas is only a short distance west of the Gulf of Mexico. The percentage of the total area that received various amounts of rainfall is shown in Table X. Thirty-nine % of the United States receives less than 20in. of rainfall, 11% receives over 50in.; one-half of the area receives from 20 to 50in.

TABLE X. *Average Annual Precipitation in the United States**

Precipitation	Land area	Per cent of total

Total	1,903,000,000	100

*U.S. Department of Agriculture *Yearbook*, 1921, p. 418.

Length of Growing Season.—The average number of days between frosts is shown in fig. 3. The area with over 240 days between frosts is sub-tropical. Citrus fruits and early vegetables are produced in the most favourable parts of this area. Most of the cotton is raised in the area with a growing season of from 200 to 240 days. The only important exception is a considerable area of cotton in the portion of Texas which has a growing season of over 240 days. Most of the winter wheat is grown in regions with a growing season of from 160 to 200 days. Most of the corn is

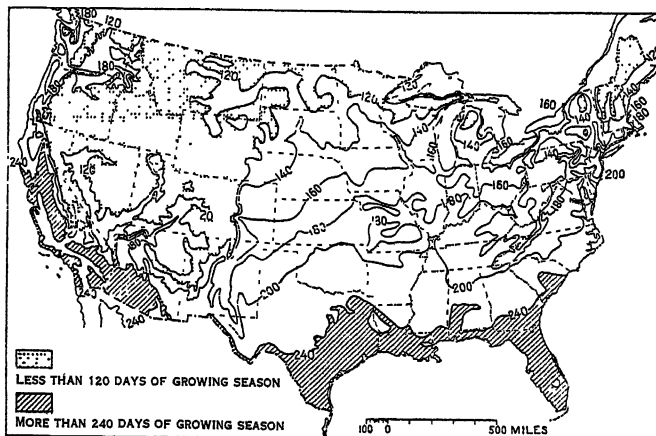

FIG. 3.—LENGTH OF GROWING SEASON

Of the land area of the United States 11% has a growing season of over 240 days, while 26% has a growing season of under 120 days

grown in regions with a growing season of 140 to 180 days. Spring wheat is primarily grown in regions with less than 140 days of growing season.

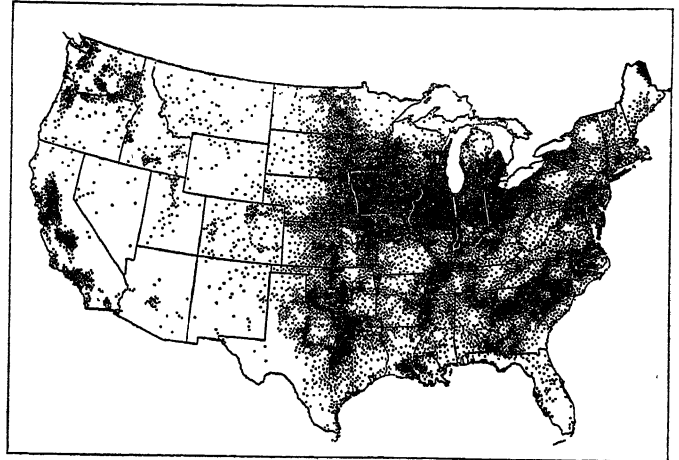

TABLE XI. *Normal Monthly Temperature in Berlin, Germany, and Des Moines, Iowa**

Date	Berlin	Des Moines
January	31.3	20.1
February	32.5	23.7
March	37.0	35.9
April	45.9	50.1
May	54.9	61.3
June	62.1	70.6
July	64.6	75.4
August	63.3	73.1
September	57.0	65.6
October	48.2	53.4
November	38.1	38.4
December	32.7	26.0
Average	47.3	49.5

*The normal monthly temperature at Des Moines, Ia., is based on a 30-year period. U.S. Department of Agriculture *Yearbook*, 1926, pp. 1,268-69; and at Berlin, Germany, is based on the 50-year period 1841-90. J. Hann, *Handbuch der Klimatologie*, p. 218, 1911.

Temperature.—The temperatures in Berlin, Germany, and Des Moines, Ia., are given in Table XI. The July temperature averaged 65° F in Berlin and 10° higher in Des Moines. The contrast shows the difference between a potato and a corn climate. A temperature that is high enough for the best yields of corn is too high for the best yields of potatoes. It is very easy for Germany to produce higher yields of potatoes than the United States and equally easy for the United States to produce higher yields of corn.

Value of Crops.—The value of all harvested crops in the United States is shown in fig. 4. This figure shows the combined

FIG. 4.—VALUE OF HARVESTED CROPS IN THE UNITED STATES, 1919
Most of the crops are grown in about one fourth of the area in regions where rainfall, soil and topography are favourable. Each dot represents \$1,000,000

effect of topography, rainfall and soil on the crop production. The areas that produce only a small amount of crops for sale are mountainous, arid or sandy. The highly productive sections of the country occupy about one-fourth of the total land area. The largest area that is highly productive is in the north-central part of the country extending from Ohio to Nebraska. There is a highly productive area south of this along the Mississippi river. A region of high crop values in Texas is caused by an area where good soils overlap on sufficient rainfall. Most of the coastal plain area from Texas to Maine and a considerable area around the Great Lakes are too sandy for most crops. Between the coastal plain area and the mountains there is a productive area extending from Alabama to Virginia. Philadelphia is in the centre of another highly productive area. Long Island, the Connecticut river valley and Aroostook county, Me., are small areas with high production. In western New York, south of Lake Ontario, is an area with level productive land. In the western half of the United States, there are many small areas of irrigated land. A number of these are indicated in fig. 4. Along the Pacific coast there are several highly productive areas.

Machinery.—This subject is also dealt with under AGRICULTURAL MACHINERY AND IMPLEMENTS.

Most of the food of the world is produced by a small number of farmers who use machinery. The millions of farmers in Asia, and other countries where machinery is not used, produce a small

TABLE XII. *Value of Farm Machinery**

Year	Per acre	Per farm	Per acre of improved land
	\$	\$	\$
1850	0.52	105	1.34
1860	0.60	120	1.51
1870	0.66	102	1.43
1880	0.76	101	1.43
1890	0.79	108	1.38
1900	0.89	131	1.81
1910	1.44	199	2.64
1920	3.76	557	7.15
1925	2.91	423	5.33

*Fourteenth Census of the United States, 1920, vol. v., p. 32.

percentage of the world's food supply. In one region in China,¹ the farmers had \$8.82 worth of machinery per farm compared with \$423 in the United States. The value of machinery per farm increased from \$108, in 1890, to \$423, in 1925 (Table XII.). A relatively small amount of machinery is used in the southern States. The average value of machinery on farms operated by white persons in the east south central States, in 1920, was \$203, but was \$1,065 in the west north central States (Table XIII.). Coloured farmers use relatively little farm machinery regardless of the section of the country in which they are located. The average value of machinery on farms operated by coloured persons was \$109, but was \$605 on farms operated by whites (Table XIII.).

East South Central	203	81
West South Central	376	101
United States	635	109

*Fourteenth Census of the United States, 1920, vol. v., p. 244.

It is not possible to understand agriculture in the United States except in terms of machinery. Not long ago ploughing was done with a one-furrow walking-plough. To-day, the most common practice is to use a two-furrow plough drawn by horses or by tractors. A large amount of work is done with ploughs that turn three furrows or more. Harrowing, disking and other operations in fitting the soil were commonly done with two horses, but to-day four or more horses or the tractor are commonly used. About 50 years ago grain-binders and threshing machines were in common use. The harvester was later developed into the twine-binder, which dropped the bundles into piles for shocking. At that time, it was necessary to cut the bands and feed the threshing machine by hand. The grain was measured and lifted into the wagon. The straw was elevated by a carrier and several persons were needed to keep it out of the way. Horses were often used for power. If a steam-engine was used, one man and a horse were required to haul the water. To-day bundles are quite commonly pitched into a pen-rack, so that no loader is required, and then pitched into the self-feeder of the threshing machine. The grain is weighed and delivered into the wagon or truck. The straw-blower takes care of the straw. The only hand labour involved in raising a grain crop is in shocking the grain, pitching the grain onto the wagon and from the wagon to the threshing machine. For a number of years, the combined harvester and thresher has been used in the Pacific coast States. When this is used, no hand labour is involved in grain production. Recently, combines are being introduced into all the States and a large percentage of the wheat is handled in this way. The use of the tractor and the combined harvester is making it possible to farm large areas of semi-arid land on which the yields were not high enough to pay before labour-saving methods were introduced. For some time the planting of corn has been done with the corn-planter, which rows the corn in both directions, two rows at once. A considerable number of farmers are now using two-row cultivators. Most of the husking is still done by hand, but power husking machines are beginning to be used. The ears of corn were formerly shovelled from the wagon to the crib. Many farmers now have elevators to do this work. Power shellers have been in universal use for some years, but recently have been improved. The only hand labour in raising corn is husking and shovelling the ears into the sheller. Not many years ago, hay was cut with a mowing machine about 4ft. wide, and raked with a horse-rake. It was then pitched

on to the wagon, then to the mow or stack. Most of the hay produced is now loaded with a hay-loader or pushed from the field to the stack on a sweep-rake. It is elevated to the stack by horsepower. In the eastern States, hay is usually loaded with a hay-loader and unloaded with a horse-fork. In either case, the only hand labour is that of making the stack or mowing away the hay. Until recently, potatoes were planted, dug and dusted or sprayed by hand to control the potato beetle. To-day, most of the commercial crop of potatoes is planted with a potato-planter, dug with machinery and sprayed with a power sprayer. The only hand labour involved is in cutting the seed, picking up the potatoes and placing them on the wagon or truck. Under some conditions, digging machines are used to pick up the potatoes. Although the majority of cows in the United States are milked by hand, about one-half of them, in intensive dairy sections, are milked with machines. Records obtained from 422 farms in New York in 1922 showed that 46% of the farmers used milking machines.

Irrigation and Drainage.—Approximately two-fifths of the United States is too dry for crop production unless irrigated or farmed with particular reference to the conservation of moisture. A part of this area is summer-fallowed. By fallowing, enough moisture is conserved so that one crop may be grown every two years. In other regions, crops are planted every year, but with the expectation that many crop failures will occur. The total rainfall in the arid area is sufficient to irrigate only a very small percentage of it. In 1919, the area under irrigation amounted to 19,191,716 acres. The systems available at that time could have irrigated 26,000,000 acres. It is estimated that this is about one-half of the land that it is possible to irrigate. Alfalfa (lucerne) is the predominant crop on irrigated land. Of the total value of the United States crop in 1919, nearly one-half of the alfalfa, practically all of the rice, most of the lemons, over one-half of the oranges and sugar beets, and one-third of the grapes and prunes were produced on irrigated land. The rice crop is grown in humid areas, but is flooded. The other irrigated crops are grown in arid or semi-arid areas.

In 1920, the land in operated drainage enterprises amounted to 65,495,038 acres. This is over three times the irrigated land. The largest areas in the drainage districts are in Ohio, Indiana, Michigan, Iowa and Minnesota. In the future, more land will continue to be reclaimed by drainage than by irrigation.

TABLE XIV. *Relative Importance of Irrigated Crops, 1919**

Crop	Per cent of value of all irrigated crops	Per cent of value of all crops for the United States
Alfalfa	22.8	44.9
Rough rice	11.8	99.1
Oranges	7.1	53.0
Potatoes	6.2	8.0
Sugar beets	4.7	62.6
Wheat	6.4	8.9
Grapes	4.4	38.0
Cotton	3.7	1.3
Apples	3.0	10.1
Peaches	3.0	25.8
Wild hay	2.2	7.9
Lemons	2.0	87.7
Prunes	1.9	37.1
All crops	5.6

*R. P. Teele, *Economics of Land Reclamation*, p. 37, 1927.

Forests.—Originally, nearly one-half of the land in the United States was covered with forests. The estimated original quantity of timber was 5,200 billion board feet, of which about 2,200 billion board feet remain. The present cutting is about four times the annual rate of growth. The United States now uses nearly one-half of the timber and over one-half of the paper of the world. It is evident that this rate of consumption cannot continue unless provision is made for growing the crop more rapidly. The majority of the States now furnish forest trees for planting

¹J. L. Buck, "An Economic and Social Survey of 150 Farms," Yenshan county, Chihli province, China, University of Nanking, *Bul.* 13, p. 30, June 1926.

at a very small charge. Thus far, the acreage planted per year has been very small. In 1926, about 53,000 ac. were planted. Farmers planted more than any other agency, followed by the Federal and State Governments. Corporations planted a relatively small percentage of the total. Farmers and other private agencies are the chief owners of forest land, but the area of national, State and municipal forests is increasing.

TABLE XV. *Area of Forest Land*

Ownership	Acres
National forest	89,100,000
State	8,700,000
Municipal	450,000
Farm woodlots	150,398,000
Other private forests	220,852,000
Total	469,500,000

Corn.—Corn is the most important crop in the United States. It is grown by more farmers, occupies more acres and has a greater total value than any other crop. About two-thirds of the farmers grew corn in 1925. No other crop, except hay, was grown by much more than one-third of the farmers. Less than 10% of the corn crop is used directly for human food. About 40% is fed to hogs, 15% to cattle, 20% to horses and 5% to poultry. Corn furnished over one-half of the feed, other than pasture, for live stock. While only a limited amount is used directly for food, corn is indirectly the most important single source of human food in the United States. Although a very large number of farmers grow corn, the chief centre of production is in the strip of land, 200m. wide and 800m. long, extending from Ohio to Nebraska. This region is known as the corn belt. It produces most of the corn of the world (fig. 5).

After corn is husked, cattle and horses are turned into the fields for pasture. In the dairy regions, a considerable amount of

corn is placed in the silo for winter feed. About 4% of the total crop is cut for silage and 7% is cut for fodder. About 5% of the corn is harvested by turning the hogs into the field.

Thus far, corn has been singularly free from devastating pests. The European corn-borer is now appearing in the eastern edge of the corn belt. As this spreads, it may cause serious reduction in

FIG. 5.—CORN PRODUCTION IN THE UNITED STATES

Corn is the most important crop in the country. Two-thirds of the farmers raise it. The region of highest production, extending from Ohio to Nebraska, is called the corn belt. Each dot represents 300,000 bushels

yields. Usually when a serious pest appears, it causes much more loss in the earlier years than later. When the natural enemies of the pest become more numerous and methods of control are better developed, the ravages are less serious.

Cotton.—Cotton is the most important cash crop grown in the United States, second only to corn in total value. Cotton is limited to the southern States. It is grown throughout the South, but there

Tobacco	6.2	Flaxseed	3,435	Barley	121	Sweet potatoes	30
Barley	5.6	Potatoes	2,911	Flaxseed	67	Rye	23
Rye	3.6	Tobacco	1,538	Rye	63	Flaxseed	22

are three centres of intensive production. One area extends across Georgia and the Carolinas, another along the Mississippi river from the northern border of Tennessee to that of Louisiana. The third intensive area is in Texas and Oklahoma. The centres of intensive production are in the northern and western portions of the cotton belt. This is due in part to the smaller injury from the boll weevil in the regions that have light rainfall or cold winters. Cotton is the most important farm product exported from the United States. About one-half of the crop is exported.

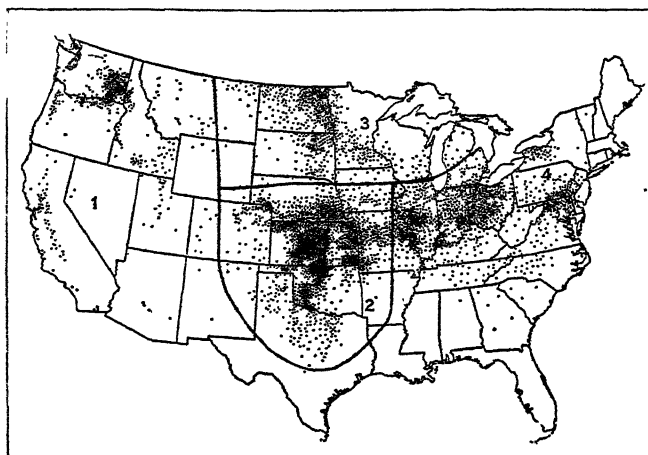

FIG. 6.—WHEAT PRODUCTION IN THE UNITED STATES
1. Soft wheat and spring wheat. 2. Hard winter wheat. 3. Hard spring wheat. 4. Soft winter wheat. Each dot represents 200,000 bushels

Wheat.—Wheat is the third crop in importance in the United States. There are four fairly distinct wheat areas. The most important one is the hard winter wheat region, of which Kansas is the centre. North of this is the hard spring wheat region. This same geographical area includes most of the wheat of Canada. East of these regions soft winter wheats are grown, although the hard wheats are encroaching on the western edge of the area. Various types of wheat are grown in the mountain and Pacific coast States, but the most important are the soft wheats grown in Oregon and Washington (fig. 6).

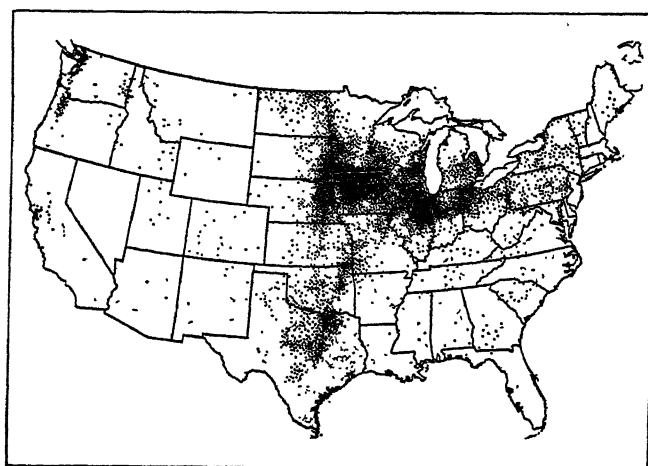

FIG. 7.—OAT ACREAGE IN THE UNITED STATES
Most of the oats are produced in the North Central parts of the country. Each dot represents 10,000 acres

Oats.—Oats are produced in many States, but the greatest production is in the corn belt. In this area they are usually grown after corn, without ploughing the ground. Oats do not give a high return per acre, but require less work (fig. 7).

Hay.—There are three more or less distinct hay areas in the United States. In the western half of the country alfalfa is the major hay crop. East of the alfalfa area and north of the cotton belt, timothy and clover are the major hay crops. South of this area, annual crops, such as cow peas, soy beans and the like, are

the primary forage crops (fig. 8). Timothy, red and alsike clover make 46% of the hay acreage. Alfalfa furnishes 14% of the hay acreage, but the yields per acre are about twice as high as the average for other hay (fig. 9).

FIG. 8.—ACRES OF ALFALFA HAY IN THE UNITED STATES
Most of the alfalfa is produced in the western half of the country. Each dot represents 2,000 acres

FIG. 9.—ACRES OF TIMOTHY AND CLOVER MIXED HAY IN THE UNITED STATES
Most of the clover and timothy hay is produced in the north-eastern quarter of the country. Each dot represents 2,000 acres

FIG. 10.—ACREAGE OF POTATOES IN THE UNITED STATES
Although potatoes are grown in most parts of the country, commercial production is limited to various areas in the Northern States and along the Atlantic coast. Each dot represents 1,000 acres

Potatoes.—Potato production is rapidly being concentrated in certain areas that have sandy soils and a cool climate. Most of the potatoes are grown in the northern tier of States or along the Atlantic coast. Formerly, potatoes were grown in small acreages

*G. F. Warren, "Prices of Farm Products in the United States." United States Department of Agriculture, *Bulletin* 999, p. 6, Aug. 26, 1921.

†Grain as reported by the Bureau of Crop Estimates, converted to pounds by multiplying corn and rye by 56, wheat by 60, oats by 32, barley and buckwheat by 48.

on heavier soils, but commercial production requires machinery, which works best on light soils. Fertilizers make it possible to obtain large yields of good quality on soils that were not strong enough for continued use before fertilizers were used (fig. 10).

Grain.—The total grain produced in the United States increased from 69 billion pounds in 1866 to nearly 294 billion in 1915. Since 1920, the general tendency of production has been downward. The production per capita was highest in the 20 years from 1895 to 1915. Since that time it has been declining. The yields per acre are considerably higher than formerly.

FIG. 11.—NUMBER OF BEEF CATTLE IN THE UNITED STATES
Beef cattle constitute over one half of the total number of cattle in the country. Each dot represents 2,000 head

Cattle.—The value of cattle and calves slaughtered represents 37% of the total value of all slaughtered animals. There are two major areas of cattle production: the timothy and clover areas where cattle are produced on pasture and hay, and the southern and western areas, where a greater dependence is placed

on the range. Many of the beef cattle are grown on the range and fattened in the corn belt (fig. 11).

The northern States from Minnesota to Massachusetts are the most important centres of dairy production, but dairy cows for

FIG. 12.—NUMBER OF DAIRY CATTLE IN THE UNITED STATES
Dairy cattle are found in all parts of the country, but most of them are raised in the north eastern quarter of the country. Each dot represents 2,000 head

milk supply are scattered wherever there are people (fig. 12). An abundance of pasture is the chief factor in economical cattle production. Some of the most favoured areas are on the Pacific coast, where good pastures are available most of the year. In most of the United States, conditions are less favourable for dairying than in England, Ireland and Holland, because the pasture season in these countries is longer. The milk production in Denmark averages about 6,300lb. per cow. The production in a number of dairy regions in the United States averages about 5,500lb. per cow. In many regions of New York State, the production aver-

ages 5,700. The dairy regions shipping milk to New York city average 6,200 pounds. Comparisons are often made between the United States and Denmark or Holland. If a significant comparison is to be made with these countries, it must be made with intensive dairy districts in the United States, because in the latter a large percentage of the cows that are milked are beef cattle.

Hogs are reared on three-fourths of the farms in the United States, but the chief centre of production is in the corn belt. Hogs eat about 40% of the corn crop. A bushel of corn pro-

FIG. 13.—NUMBER OF HOGS IN THE UNITED STATES

Although hog production is almost as widely scattered over the country as population, the corn belt is the chief centre of intensive pork production. Each dot represents 5,000 head

duces a little more than 10 lb. of live hog, or from 7 to 8 lb. of pork. Pork is produced in the United States in sufficient quantities to supply home demand and forms a chief export (fig. 13).

Pure-bred Live-stock.—In 1920, the U.S. census reported 1,981,514 registered pure-bred cattle and 2,049,900 registered hogs in the United States. This is a small percentage of the total pure-bred animals, as many are not registered. The registrations

probably indicate the relative numbers of the different breeds and the blood characteristics of the grade animals. Shorthorn and Hereford cattle are the most important beef breeds in the United States (Table XX.). Nearly all of the steers that go to market are typical Shorthorn, Hereford or Angus cattle. The majority of the dairy cattle are Holstein-Friesian or Jersey, although Guernsey are rapidly increasing. In the southern States, the majority of the cattle are of the Jersey type; in the northern States, the majority are of the Holstein-Friesian type, but the Jersey, Guernsey and Ayrshire types are quite numerous. •

Pure-bred hogs in the United States are predominantly Duroc-Jersey and Poland China. The three most important breeds of hogs as well as many of the important breeds of poultry are of American origin, but the important breeds of cattle, sheep and horses are European.

In the eastern half of the United States Shropshire sheep predominate. Rambouillet are grown in all parts of the country, but are very numerous on the ranges of the West.

Percheron horses predominate, but there are considerable numbers of Belgian, Shire and Clydesdale horses.

FIG. 14.—CROP YIELDS PER ACRE EAST OF THE MISSISSIPPI RIVER, 1866-1927

Yields declined during the agricultural depression of the '80s and rose rapidly thereafter. The increase was stopped by the agricultural depression following the World War

Crop Yields.—Comparisons of yields of small grains and potatoes in Europe and the United States are often made and erroneous conclusions drawn. This is often assumed to be due to differences in methods of farming. However, they are due primarily to climate. Most parts of the United States are too hot for

TABLE XXI. Crop Yields Per Acre, in Bushels, 1921-25*

	Corn	Wheat	Rye	Oats	Barley	Potatoes
United States . . .	27.7	13.8	13.9	30.8	24.8	107
Europe	19.3	18.4	20.5	35.8	23.4	169
Asia	11.8
Southern hemisphere	21.4	12.3	13.7	103

France	17.8	21.5	18.5	35.3	26.6	125

*U.S. Department of Agriculture Yearbook, 1926.

the best yields of small grains and potatoes. The yields of these crops are much below the European, but corn yields are much higher. Europe obtains 5 bu. more wheat and oats per acre than the United States, but produces 8 bu. less corn (Table XXI.). The best yields of small grains are obtained in countries too cool to

raise corn. The yields of potatoes in Belgium are over twice the yields in France. The small grains yield nearly twice as much as they do in France. France is warm enough to obtain small yields of corn, whereas Belgium raises practically none. The yields of all small grains and potatoes in France are higher than in the United States. Wheat yields are 8 bu. higher, but corn yields are 8 bu. less. The same comparisons are shown in different parts of the United States. The average yield of potatoes in Maine is higher than that in Germany, England or France, and nearly as high as that of Belgium (fig. 14).

The yields of small grains and potatoes in Maine are higher than those in Iowa, but Iowa yields of corn averaged nearly 40bu., while Maine raises very little of this crop. The small-grain yields in Iowa are about the same as those in France, but corn yields are twice as high. The only part of the United States that has a climate approximating that of Europe is in the State of Washington, west of the Cascade mountains. Some of the counties in this region had yields of over 40bu. of wheat per acre in 1925, and 75 to 80bu. of oats. Crop yields are exceedingly variable. The yearly variations and the long-time tendencies are shown in fig. 14. The low prices in the period of the over-expansion from 1880-90 caused yields to decline. Rising prices caused yields to increase. The rapid advance was checked by the agricultural depression following the World War.

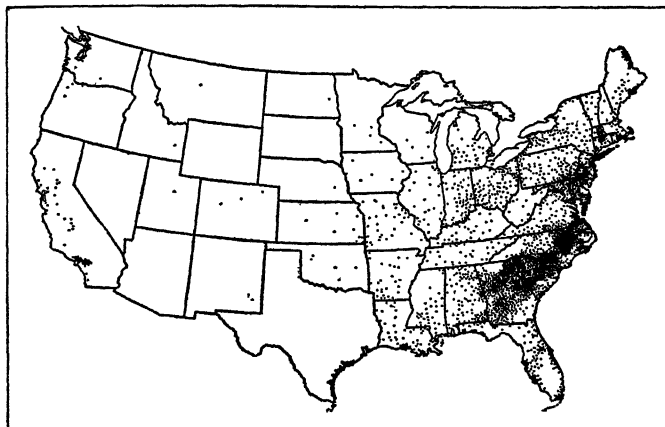

FIG. 15.—FARM EXPENDITURES FOR FERTILIZERS

Most of the fertilizer is used on the cotton, tobacco and garden crops along the Atlantic coast. Each dot represents 100,000 lbs.

Fertilizers.—A very small amount of fertilizer is used on general farm crops. Most of it is used for cotton, tobacco, potatoes and truck-crops on the sandy soils of the Atlantic coast (fig. 15). The quantity of fertilizer used is decidedly variable from year to year, depending primarily upon prices received for cotton and tobacco in the preceding year. About two-thirds of the total fertilizer is acid phosphate. Ground limestone is not listed among the fertilizer materials in Table XXII., but is one of the very important materials needed on American soils.

TABLE XXII. *Relative Importance of Fertilizer Material Used in the United States**

Material	Tons
Phosphorus group:	
Acid phosphate	4,600,000
Raw ground bones	102,000
Ground steamed bones	57,000
Organic nitrogen group:	
Tankage	790,000
Cottonseed-meal	280,000
Fish scrap	260,000
Mineral nitrogen group:	
Nitrate of soda	153,000
Sulphate of ammonia	143,000
Potassium group:	
Kainit	405,000
Muriate of potash	215,000
Manure salts	209,000
Sulphate of potash	41,000

*E. E. Vial, "Prices of Fertilizer Materials and Factors Affecting the Fertilizer Tonnage," Cornell University Agricultural Experiment Station, *Memoir* 119, 1928.

Most of the soils in the eastern half of the United States need limestone for the best growth of clover. In recent years, methods of grinding limestone have been so cheapened that vast quantities will be used as soon as agriculture becomes more profitable.

Cropping Systems.—In most parts of the United States certain principles of cropping are followed, but fixed rotations are not common. In regions where timothy and clover are grown, they are

usually seeded with wheat or oats. If corn, oats, wheat, timothy and clover are grown, they are commonly planted in that order. In the better parts of the corn belt, corn may be planted two or more years before it is followed by oats. From southern Pennsylvania to Kansas, there is a region which is too hot for oats. Corn can be harvested early enough to plant winter wheat. The common rotation is corn, wheat and clover. In the northern States, potatoes are commonly grown in a three-year rotation of potatoes, oats and clover. Alfalfa lives so long that it is usually left for an indefinite number of years. Corn follows alfalfa when grown in rotation with it. In the cotton belt considerable land is planted in cotton year after year, but an increasing number of farmers are using cow peas, velvet beans or other legumes in the rotation. In the arid regions, wheat is the pre-eminent crop. Since it pays so much better than most other crops, much of the land is planted to wheat for many years in succession.

Diversity.—When a self-sufficient agriculture was followed, each farmer grew many kinds of crops. This system was very wasteful of time. No region is well adapted to all crops, so that low yields were often obtained. The small acreage required a large amount of time per acre. A large production was not required, because all that was necessary was to supply the farmers' needs. With the introduction of machinery, it became necessary to have an income and sufficient acreage to use machinery effectively. There has been a steady movement to grow the major part of each crop in the region that is best adapted to it. Most farming communities specialize on one or a few products. For instance, 82% of the hens in Sonoma county, Calif., in 1924 were kept in flocks of over 900; 50% in Suffolk county, Long Island, N.Y., were kept in flocks of more than 450. One-half of the cows in New York State are in herds of 20 or more.

In some regions, several products pay about equally well. Such regions are quite diversified. In others, the second-best product yields a very poor return, compared with the best. Such regions are highly specialized. Cotton, peanuts and tobacco have been increasing so rapidly that the percentage of farms reporting them increased in the 25 years ending with 1924 (Table XXIII.). The acreage per farm also increased. For nearly all the other crops, the percentage of farmers growing the crop decreased in the 25-year period. In every case shown in Table XXIII., and for nearly all other crops, the acreage grown per farm increased.

TABLE XXIII. *Per Cent of Farms Growing Each Crop and Acres Grown per Farm*

	Per cent of farms reporting		Acres per farm reporting	
	1899	1924	1899	1924
Corn	81.9	74.7	20.2	20.7
Oats	36.9	34.1	14.0	18.8
Rye	5.1	3.6	7.0	16.3
Potatoes	49.4	36.5	1.0	1.3
Sweet potatoes	17.5	10.8	0.5	0.7
Cotton	24.7	30.3	17.1	20.3
Peanuts	2.3	3.9	3.9	4.4
Tobacco	5.4	6.2	3.6	3.9
Tomatoes	5.3	2.9	0.7	2.3
Cabbage	6.0	1.9	0.4	1.4
Beans, dry	4.3	2.4	1.9	10.9
Onions, dry	4.3	0.9	0.2	1.6

The increases are particularly striking for vegetables and other minor crops. The farmer who grew lettuce in the mountain States produced an average of 5ac. per farm, and on the Pacific coast 9 acres. In the Pacific coast States, those who grew beans raised 38ac. per farm. Those who grew sugar beets in the mountain States grew 18ac. per farm. In the west north central States those who grew corn raised an average of 45ac. Those who grew winter wheat raised an average of 65ac.

The percentage of the farmers growing hogs decreased from 68 to 57 in 15 years, and those keeping dairy cows decreased from 81 to 59%. The percentage keeping poultry decreased only slightly, but the number of chickens kept per farm increased nearly 50%. A considerable part of this is due to the establish-

ment of large commercial flocks of from several hundred to several thousand hens.

TABLE XXIV. *Number of Farms Reporting Each Kind of Live-Stock and Number of Head per Farm*

	Per cent of farms reporting		Number of head per farm	
	1910	1925	1910	1925
Hogs	68	57	13	14
Dairy cows	81	59	4	6
Sheep	10	7	86	83
Chickens	88	86	50	74

Co-operation.—There has been a rapid increase in the amount of business done co-operatively. In 1924, 14% of the farmers marketed their products co-operatively and 6% did some co-operative buying. In some parts of the country co-operative fire

TABLE XXV. *Value of Farm Products Purchased and Sold Co-operatively, 1924**

Division	Amount purchased co-operatively	Amount sold co-operatively
	\$	\$
New England	5,709,116	20,745,326
Middle Atlantic	7,376,663	50,273,909

Mountain	1,709,581	35,043,394
Pacific	9,384,978	115,871,386
United States	75,971,169	858,284,387

*U.S. Census of Agriculture, 1925, pt. 2, pp. 16-18.

insurance is practically universal. Large numbers of farmers borrow co-operatively through the Federal land banks. In 1924, the farmers purchased \$76,000,000 worth of products co-operatively, and sales amounted to \$858,000,000. In Iowa, tenants did

In Feb. 1928, there were 461,719 farmers using the system. The total loans outstanding amounted to \$1,463,918,114.

The land-bank system is under the general supervision of the Farm Loan board, which is appointed by the President of the United States. Each bank is managed by a board of directors. Three of them are appointed by the Farm Loan board, four are elected by the borrowers, but the seventh is subject to approval by the Farm Loan board. The banks obtain their funds through the sale of bonds to the investing public. They cannot charge the borrower more than 1% above the rate paid on the bonds. The Federal Land Bank bonds sell at a low rate of interest, so that these banks are usually the first to reduce interest rates. All the profits above the amount set up as reserves are returned to the borrowers as dividends on the stock held by the farmers who borrow. Each borrower is required to invest \$5 in stock for each \$100 borrowed. Most of the loans are made for 20 or 36 years. When the banks were first started, the usual method of payment was 1% on the principal the first year and an equal total payment in each successive year. The interest payments steadily declined and the payments on principal steadily increased. A form of loan now coming into general use requires payment of the total principal in 20 or 33 years by paying 5 or 3 percent of it each year, in addition to payment of interest. This makes the total payment decrease each year. It allows the farmer to pay more than one instalment on the principal when he has a good year and skip payment in a bad year, provided he had paid in advance in the good year.

The portion of the mortgage business done by the co-operative Federal land banks is rapidly increasing. Life insurance companies, private land banks, mortgage companies, banks and individuals also lend money on farm mortgages. The Federal Intermediate credit banks owned by the Federal Government, but managed by the land bank officers, lend money to marketing agencies on warehouse receipts and discount notes for banks and credit corporations. Most of the short-time credit used by farmers is furnished by banks or by dealers who sell goods on time. For tenant farms, landlords supply considerable credit. It is expensive for dealers to furnish credit; consequently farmers pay a very high rate of interest. Part is paid as interest, but a large part is covered by charging a high price. Mortgage credit is readily

almost twice as much co-operative purchasing and selling as did the owners. Grain, dairy products and live-stock were the leading products handled.

Credit.—Co-operative credit is available through the 12 Federal land banks. Although called Federal, the Federal Government owns no share in eight banks, and only 1% of the total stock of the 12 banks; all other stock is owned by the borrowers.

available on easy terms, but equally good short-time credit facilities have not been developed.

Roads.—Now that the horse has been so largely supplanted by automobiles and trucks, the road question has become of great importance to farmers. Roads are used even more as interurban thoroughfares than by farmers. Formerly all roads were considered local and practically all support came from the localities.

Now that roads have become national, farmers are often taxed to build roads for city use. On the primary highways in Pennsylvania, New York and Maine, 5% of the traffic was farm travel, in Georgia, 9%, and in Illinois, 10%. Much more than this percentage of maintenance is usually contributed by farmers. In 1925, 7.5% of the farms were on hard-surfaced roads and 15% on gravelled roads. The percentage on hard-surfaced roads was highest in the Middle Atlantic States, averaging 22%, but the percentage on either hard-surfaced or gravelled roads was highest in the east north central and Pacific States (Table XXVII.). From the standpoint of agriculture, the most important problems are the increase in the number of lateral roads and an adjustment in the methods of financing so that the local communities will pay no higher percentage of the cost of construction of these roads than their use is of the total use.

TABLE XXVII. *Per Cent of Total Number of Farms on Different Kinds of Roads, 1925*

Division	Concrete	Macadam	Gravel	Improved dirt	Unimproved dirt	All others
New England	1.3	12.0	24.4	22.4	38.1	1.8

United States	2.5	5.0	14.9	31.4	43.1	3.2

Tenancy.—About two-fifths of the farms in the United States are operated by tenants and the percentage is increasing. As the amount of machinery and other capital necessary to start farming increases, a longer time is required for a hired man to accumulate enough property to become an owner.

The percentage of tenancy is highest in the southern States where there are many negro tenants, and in the Middle West, where the capital per farm is high (Table XXVIII.). In New England, only 7% of the farms are operated by tenants and in the west south central States 53% are so operated (Table XXIX.). The most common form of tenancy is to share the crop for the farm. In regions where live-stock is produced in considerable quantities, the live-stock products are also shared. About one-fifth of the tenants pay cash rent. When a share of the product is given as rent, the fraction is usually one-third, two-fifths, one-half, etc. The difference between two-fifths and one-half may be very large when expressed in dollars. For this reason, a considerable number of share tenants pay some cash in order that the contract may be more closely adjusted to the value of the lease (Table XXX.).

In the cotton belt, two other forms of tenure have been adopted, primarily for negro tenants who require close supervision. One of these is called standing rent, in which the tenant pays a given quantity of cotton or other crop, regardless of the yield. All that he raises above this quantity is his own. This is intended to encourage more attention to the crop.

TABLE XXVIII. *Number of Farms in the United States Classified by Tenure, 1880-1920**

Year	Number of owners and managers	Number of tenants	Per cent tenants
1880	2,984,306	1,024,601	26

	Number
Share tenants	1,117,721
Croppers	561,091
Share-cash	127,822
Cash tenants	480,009
Standing renters	104,996
Unclassified	63,165
Total	2,454,804

*Fourteenth Census of the United States, 1920, vol. v., p. 148.

The cropper system is also classed as tenant farming, but is, in reality, half way between hired labour and tenancy. The owner of the farm furnishes mules and equipment, feed, fertilizer and living expenses for the worker. The worker receives a share of the crop and agrees to repay money advanced for his living. If the crop is good, payment is made; if not, the landlord may lose the money.

Farm Labour.—Before the World War, wages of farm labour were highest in the western States. Following the war, competition with nearby cities made farm wages in New York higher than in the West. Wages are lowest in the southern States, the average monthly payment in Alabama being less than one-half of those in the North (Table XXXI.).

*The quarterly wages published by the U.S. Department of Agriculture were weighted in the following manner to obtain the average yearly wage rate: April 1; July 2; October 2; and the following January 1.

Farm wages are influenced by prices of farm products and by conditions of employment and wages in cities. Near industrial centres, city wages have more effect on farm wages than do prices of farm products. For the United States as a whole, the wages of farm labour are influenced more by prices than by city wages (fig. 16). The average hours worked by farm operators per year are 3,020, but there is great variation from this average in different areas. The negroes take so many holidays that the farm labour

reported for some of the southern States amounts to only 2,034 hours. The total for Wisconsin is 3,421 hours. Since this is a dairy State, a large amount of work is done on Sundays and in all seasons. The Wisconsin farmer works about two-thirds more hours than farmers in some of the southern States and many more than farmers in China. Hard work is an important factor in the prosperity of the American farmer. He spends more years in school than does the Asiatic or negro farmer. He works more hours per year and usually is able to retire earlier. He may work fewer hours in his lifetime than the Asiatic farmer. In the regions

compared with those of Europe or Asia, they are small if measured in terms of workers. The labour force of the average farm consists of the operator, one hired man for each three farms and one member of the family assisting the operator for each three farms. The average farm, therefore, has less than two workers (Table XXXII.).

FIG. 16.—PRICES RECEIVED BY FARMERS FOR FARM PRODUCTS, FARM WAGES, CITY WAGES, 1910-1914 = 100 ON GRAPH

When farm prices rose, farm wages rose more rapidly than city wages. When farm prices fell, farm wages fell, but city wages remained high. Farm wages are more affected by farm prices than by city wages

that depend on crops, the amount of work during the summer is much higher than in the winter. Because of the use of machinery and the character of the population, the amount of work done per worker is very great. In China and India, there are 2 ac. of crop-land per worker engaged in agriculture; in England, 9; and in Iowa, 56. When the high yield of corn per acre is considered, this large acreage indicates the very high production per worker in Iowa. The production per worker in the southern States is much lower because negroes do so much of the work. They accomplish much less per hour because so little machinery is used. There are only 10 ac. of crops per person engaged in agriculture in South Carolina. While farms in the United States are large in acreage

Yields per acre in the United States are lower than in western Europe, but crop acres per worker are so much higher that the production per worker is about three times as much as in Europe, and six times as much as in Italy. From 1910-25, the population of the United States increased 23,000,000, but the farm population decreased over 3,000,000, in spite of which, the crop production increased about 10%. In 1925, the farm population was 28,984,221, or one-fourth of the total population.

Many more children are born on farms than are needed to do the farm work. Probably about one-half of the farm children go to cities. There is a constant movement from farms to cities and a smaller flow from cities to farms. A ten-year study of this question in New York State showed that on the average, about five persons went to cities from the farm for about every two persons that left the cities for the farm. The rate of movement from year to year was primarily dependent on conditions of city employment and profits of farming. In 1920, the net movement from New York farms to cities was 24,000. The following year, unemployment in cities was serious and the net movement was only 3,000.

*U.S. Department of Agriculture, *Yearbook*, 1926, pp. 1,177-80.

Exports and Imports.—The chief agricultural exports are cotton, wheat and pork. Nearly one-half of the cotton crop is exported. For a number of years before the World War, exports of food products declined, but exports of cotton increased. In the war period, there was a great increase in exports of food, but a decline in exports of cotton. After the war, food exports declined rapidly, but exports of cotton increased.

About three-fourths of the pork exported goes to Europe. Considerable pickled pork and pickled beef go to tropical countries. Most of the cotton and wheat go to Europe. Condensed milk, powdered milk, cheese and eggs are exported to tropical countries. As a whole, the major exports go to Europe and the major imports come from the tropics. The chief agricultural imports are sugar, coffee, hides, rubber and wool, all of which have constantly increased (Tables XXXIII., XXXIV., p. 416).

Taxation.—The usual method of farm taxation in the United States is a capital levy. The farms are assessed on the estimated value at market prices. In most States, machinery, live-stock and other personal property are similarly appraised. A certain percentage of this appraisal value is taken for school taxes, another for local and State taxes. A few States do not levy direct taxes for State purposes. Farmers contribute very little direct taxes to the Federal Government, as it levies no taxes on property. This system of taxation was fairly satisfactory when conditions were so uniform that the market price of a property represented its income-producing power. Such a method of taxation is unfair to industries with a slow turn-over. The most striking cases are forests and orchards, which give no returns for many years; agriculture as a whole has a very slow turn-over compared with commerce (Table XXXV.).

So much income is now derived from salaries, copyrights, patents, use of mails in advertising, etc., that real estate is no longer a good measure of ability to pay. Another difficulty is that railroads and manufacturing plants derive their revenue from large areas, but when taxed as real estate in some political unit, the tax does not go to the regions that contribute the business. With the growth in total taxes, considerable dissatisfaction with this method of taxation is developing. A few States are discontinuing direct property taxes and most States are raising an increasing percentage of their income from other sources. However, revenues for schools, roads and local government are based on property. Dissatisfaction with this system is resulting in increased aid for schools and roads from the State and nation.

The changes in taxes on a few farms in New York State indicate the increasing burden of taxation. One hundred years ago, six days of labour at farm wages were required to pay the taxes, but now about 37 days are required. The taxes could have been paid with 3bu. of wheat, but 104bu. are now necessary. In most States, taxes were from two to nearly three times as high after the World War as before. They rose almost directly in proportion to wages. The major portion of the farm taxes are spent for labour and for salaries of school teachers and other public employees. Therefore, they rise as these payments advance.

Land Values.—The average value per acre of farms in the United States nearly doubled in the 50 years ending with 1900 and doubled in the following 10 years. Prices declined from 1870-80, and from 1890-1900. They rose rapidly from 1910-20 and declined thereafter. The rise in the price of farm-land does not indicate an increase in the value of the same property. Thousands

of acres of land were drained. Many new buildings were erected and others improved. Land was cleared, fences were built, orchards were planted. There is no way of telling what portion

Acres of land that a month's labour at farm wages would buy	0.44	0.65	0.62	0.70	0.49	0.68	0.71

of the increase was due to improvements and what portion to rising prices. Prices in typical States are shown in Table XXXVI. The corn belt is the region of highest land price and has shown the greatest increase in prices.

The acres of land that could be bought with the cash paid for a month's labour in addition to board, are shown in Table XXXVI. The largest amount of land that could be bought with a month's labour was in 1925 when one-half more land could be purchased than in 1870 or 1910. Some farmers acquire land by gift or inheritance, but the majority acquire it by working as hired men or as tenants. The most common single method is to work as a hired man and later as a tenant.

Prices.—American agriculture is characterized by family farms operated with machinery on a commercial basis. When the chief purpose of the farmer was to raise his own supplies, prices were of minor concern. A large crop was an occasion for thanksgiving and was in fact the origin of Thanksgiving Day. With commercial agriculture, a large crop usually brings the American farmers less than a small crop. Formerly, a large crop meant that the farmer would live well. To-day, with commercial agriculture, it means that he lives poorly.

The relations of the size of the corn crop to prices paid to farmers in Iowa, and to prices in Chicago and Liverpool, are shown in Table XXXVII. Relation of the Size of United States Crops to Prices*

Crop	Crop 20% below normal	Crop 20% above normal
	Percentage that prices were above normal	Percentage that prices were below normal
Potatoes:		
Minnesota farm price (1895-1915)	50	28
Rhode Island farm price (1895-1915)	22	15
Corn:		
Iowa farm price (1877-1913)	42	25
Chicago wholesale price (1876-1913)	26	17
Liverpool wholesale price (1898-1913)	15	11
Beef cattle:		
Nebraska farm price (1890-1914)	50	28
Chicago wholesale price (1890-1914)	17	12
United States retail price (1890-1914)	15	11

*G. F. Warner and F. A. Pearson, "Inter-relationships of Supply and Price," *Cornell University Agricultural Experiment Station Bulletin 466*, Sept. 1927.

in fig. 17 and Table XXXVII. A crop 20% below normal ordinarily sells for about 42% above the normal price on Iowa farms, but brings only 15% above the normal price in Liverpool. A crop 20% above normal ordinarily sells for about 25% below normal prices in Iowa, but prices in Liverpool are depressed only about 11%. Retail prices of corn meal are only slightly affected by the size of the corn crop. A crop of potatoes 20% above normal depresses the Minnesota farm price 28%, but reduces the Rhode Island farm price only 15%. The smaller reduction in price in Rhode Island is because farmers there are so near the consumers that the farm price is more like a retail price. Most of the American farm products are so far from consumers, that prices fluctuate with extreme violence. Prices to European farmers usually fluctuate less, not only because farmers are nearer the consumers, but because so large a part of the product is consumed on the farms. Commercial production far from consumers results

PURCHASING POWER

FIG. 18.—PURCHASING POWER OF THE PRICE OF HEAVY HOGS AT CHICAGO, 1860-1927

The centres of the major cycles of low prices are from 5 to 8 years apart. If this cycle is of usual length, hogs may decline in purchasing power

PURCHASING POWER

FIG. 19.—PURCHASING POWER OF THE PRICE OF SHEEP IN THE UNITED STATES, 1880-1928

Sheep have periods of high and low prices, usually lasting about 4 or 5 years. On Jan. 1, 1928, the purchasing power of sheep was the highest ever known, 175

PURCHASING POWER

FIG. 20.—PURCHASING POWER OF PRICE OF BEEF CATTLE AND DAIRY COWS IN THE UNITED STATES, 1880-1928

The major centres of high and low prices of dairy cows and beef cattle occur at the same time. The periods of high prices are about 16 years apart. The last high period was in 1915

in violent price fluctuations. In agriculture, this problem is comparable with that of unemployment in cities.

For most industrial products, a year of high prices is one of high production, because it takes such a short time to produce goods. In agriculture, a much longer time is required to produce. High prices result in increased production, but it is from one to many years before the increased product appears on the market. A retail price of round steak, 20% above normal, results in receipts of cattle at Chicago 32% above normal 8 years later. When

prices are low, animals are thrown on the market and production is checked, but it is some years before the shortage occurs. The periods of high prices of hogs are 5-8 years apart; for sheep, 4-5 years; for beef cattle, about 16 years; for horses, 25 years (figs. 18, 19, 20 and 21).

Cost of Distribution.—In 1917, beef sold at retail in the United States for an average of 23.11¢ per pound. Farmers received 8.14¢ per pound for beef cattle. There was a difference of

FROM "FARM ECONOMICS"

FIG. 21.—PURCHASING POWER OF THE PRICE OF HORSES IN THE UNITED STATES, 1880-1928

Periods of high prices usually are about 25 years apart. Apparently the price of horses has begun to advance

FIG. 22.—COMPARISON IN COST OF DISTRIBUTING BEEF WITH EARNINGS OF NEW YORK FACTORY WORKERS

Costs of food distribution follow wages, but because of increases in efficiency have risen less rapidly than wages

FIG. 23.—INDEX NUMBERS OF THE UNITED STATES FARM PRICE OF FOODS, COST OF DISTRIBUTION AND THE UNITED STATES RETAIL PRICE From 1916 to 1920, costs of distribution were low and farm prices were relatively high. Since 1920, costs of distribution have been high and farm prices low

14.97¢ between the farmer and the consumer. In 1921, beef cattle retailed at 25.59¢ per pound, but farmers received only 5.53 cents. In 1917, the retail receipts from a 1,000lb. live steer amounted to \$143.70. In 1921, they amounted to \$159.20. In 1917, it cost \$62.30 to distribute the beef and in 1921 it cost \$103.92, so that farmers received \$81.40 in the first case and \$55.30 in the second. Some persons believe that the lower farm price in 1921 was due to over-production, but retail prices were higher than in 1917.

For the five years before the World War, the average cost of distributing the beef from a 1,000lb. steer was \$49. Following the World War, it was over twice as much. In each case, the farmer received the balance. The cost of distributing foods is primarily city wages (fig. 22). When financial inflation occurs, wages and the cost of distribution are low, relative to retail prices, and farm prices are very high. When financial deflation occurs, wages and the cost of distribution remain high and farm prices are low compared with retail prices (fig. 23).

(G. F. W.; F. A. PE.)

Agricultural Chemistry.—Agricultural chemical investigations in the United States are conducted in the various bureaux of the Federal Department of Agriculture, in the agricultural experiment stations of the States, in many universities and research institutions and in the laboratories of various industrial establishments.

The chemical control of commercial fertilizers and the study of fertilizer action upon the growth of crops engaged at first almost the exclusive attention of agricultural chemists in the United States. The study of cattle feeds for regulatory and research purposes was next taken up and finally, with the passage of State and Federal pure food laws, the diet of man began to be investigated—first for the prevention of adulteration and then for the improvement of human nutrition. The sequence of plant, animal and man, although apparently illogical as regards importance, was the natural order of research development. The passage of State and Federal laws governing the purity of insecticides made a further increase in the regulatory activities of agricultural chemists in America and the experiment stations began to find their investigational work so seriously disturbed by regulatory interferences that many of these institutions felt obliged to transfer all work of chemical control to State chemists. The policy of separating research and control work has been adopted by most of the State experiment stations. It was put into effect in the U.S. Department of Agriculture in 1927, when the execution of the Food and Drugs Act, the Insecticides Act, the Tea Inspection Act and the Naval Stores Act was transferred from the Bureau of Chemistry to the purely regulatory Office of Food, Drug and Insecticide Administration. The agricultural chemical research work of the department upon soils, fertilizers, foods, etc., was consolidated in a new Bureau of Chemistry and Soils.

A survey of the last classified list of projects of the U.S. agricultural experiment stations shows that of a total of 6,610 projects some 1,400, or about 21%, involve various applications of chemistry to agriculture. Of these 412 relate to fertilizers and fertilizer experimentation, 188 to soils and waters, 172 to animal nutrition and 117 to human nutrition. Agricultural chemical investigations as a whole follow the numerical order of plant nutrition, animal nutrition and human nutrition. Individual State experiment stations specialize in particular types of research, lysimeter studies upon percolation in soils, for example, being given the most attention in Tennessee, soil acidity in Rhode Island, alkaline soils in California, vegetable proteins in Connecticut and animal calorimetry in Pennsylvania. The lines of investigation depend naturally upon the predominating agricultural needs of each section, chemical investigations upon dairy products being stressed by New York, Wisconsin and other large milk-producing States, those upon flour by Minnesota and the other wheat-growing States, those upon sugar production by the cane-growing States of the South and the beet-producing States of the West and those upon corn by Iowa and other large corn-growing States of the Middle West. The most active subject of agricultural chemical research in America at the present time is that of vitamins, 23 of the State experiment stations conducting investigations in this field. Other investigations upon vitamins are being carried out in the research laboratories of various universities and in the bureaux of the U.S. Department of Agriculture.

In the U.S. Department of Agriculture agricultural chemical researches are conducted in the bureaux of chemistry and soils, plant industry, animal industry, dairy industry, forestry, entomology, home economics and agricultural economics. Among the more important chemical projects of these bureaux are investiga-

tions upon soils, fertilizers and nitrogen fixation; foods and food technology; human and animal nutrition; plant constituents; insecticides and fungicides; chemistry and technology of tanning materials, leather, paper, farm fabrics, sugar, starch, oils and fats; meat products, dairy products, forestry products, etc.; storage of fruits, cereals and vegetables; utilization of farm wastes; spontaneous combustion; deterioration of agricultural products; explosions of agricultural dusts; and methods of agricultural chemical analysis. Important agricultural chemical researches are also conducted in the United States in the laboratories of the large packing houses and other industries which utilize agricultural products.

The most important agricultural chemical organization in the United States is the Association of Official Agricultural Chemists (established 1884) which publishes a journal and books of methods upon agricultural chemical analysis. (C. A. B.)

EXPERIMENT STATIONS

In the United States experiments were early conducted by the agricultural colleges, but not until 1875 was the first American experiment station with State support established. This was situated at Middletown, Conn., under Dr. W. O. Atwater, and later removed to New Haven with Dr. S. W. Johnson as director. It still survives as the oldest American station. The University of California next provided funds for a station at Berkeley, under the leadership of Dr. E. W. Hilgard. Other States soon followed, so that by 1887 there were about 18 stations, some with meagre support.

The movement for a nationally supported system of experiment stations culminated in the passage of an act approved on March 2, 1887, and designated the Hatch Act, in honour of its champion, Hon. William H. Hatch. It authorized an annual appropriation of \$15,000 for an experiment station in connection with each of the agricultural colleges established under the Land Grant Act of 1862. This gave a marked impetus to the experiment stations, and States which had not previously provided them promptly took advantage of the act. In 1906 the fund was supplemented by the Adams Act, designed especially to promote original scientific investigation of agricultural problems. On its maturity in 1911 this act doubled the annual Federal support. This was again enlarged in 1925 by the Purnell Act, which authorized an increase of \$20,000 to each State the first year, with annual additions of \$10,000 until \$60,000 was reached and also extended the scope of research to include agricultural economics, home economics and rural sociology. In addition to the grants under the two previous acts, each State will thus receive \$90,000 in 1930, or an aggregate of \$4,320,000. The Federal grants are liberally supplemented by State appropriations, aggregating about three times those from the Federal Government. In Alaska, Hawaii, Porto Rico, Guam and the Virgin islands, experiment stations are maintained with special congressional appropriations under the Federal Department of Agriculture. The first was established in Alaska in 1898. Experimental work in the Philippines is under the insular Government, and receives no financial support from the United States.

The Federal Department of Agriculture aids in promoting the purposes of the stations through a central office of experiment stations, which exercise supervisory control over the Federal appropriations, maintains intimate relations with the stations in all the States, has charge of the insular stations, and issues a journal, the *Experiment Station Record*, begun in 1889, which reviews the publications on agricultural research throughout the world. The office also publishes an annual report on the progress of the stations. There has thus been developed a comprehensive and closely knit system of experiment stations, co-operating with one another and with the Department of Agriculture, and supported jointly by the States and the general Government. Total appropriations for the fiscal year 1927 aggregated \$12,733,000, including \$233,980 for the insular stations. The stations employed 2,831 persons in administration and research, some of them only part time, in addition to clerks, labourers and temporary help. Many of the States also provide branch stations or sub-stations

dealing with special enterprises, such as citrus fruits, sugar, rice, tobacco, or with the special problems of localities.

In addition to the stations receiving the benefits of the Federal Acts, a number of special stations have been provided in the States, such as the poultry and fruit stations in Missouri, the coastal plain station in Georgia, the truck station in Virginia, the institute of animal nutrition in Pennsylvania, and the stations for the sugar and pineapple industries in Hawaii. In this connection, mention should also be made of the privately supported Boyce Thompson Institute for plant research at Yonkers, N.Y., opened in 1924; the Food Research Institute at Stanford university, for studying problems connected with food supply, consumption and distribution; and the Marble Laboratory at Canton, Pa., equipped for study of fruit storage.

The State experiment stations have experimental fields and trial grounds; accommodation for experimental animals; insectariums; creameries and cheese factories; veterinary hospitals; and laboratories for chemical, botanical and bacteriological study (see AGRICULTURE IN THE UNITED STATES: *Agricultural Chemistry*).

All the stations publish bulletins, circulars and annual reports dealing with the results of their work, and these are sent through the mails free of postage. Many popular articles are prepared for the Press, while the more technical features of research are published in appropriate scientific journals. The stations are in close contact with the farming public and with extension workers. The results of experiments are thus spread broadcast, often being applicable far beyond the boundaries of the State in which the investigations were carried on. (E. W. A.)

AGRICULTURE, BOARD OF: see GOVERNMENT DEPARTMENTS.

AGRICULTURE, CENSUS OF. The term "census" originally was restricted to a periodical enumeration of the population of a country by its Government, but its significance has widened. It is now applied to any systematic statistical enquiry, on a wide scale, into the economic or sociological conditions of the population or a section of it. Special enquiries in connection with agriculture have been made either annually or at less frequent intervals in many countries for a considerable period (see AGRICULTURAL STATISTICS), but they were limited in scope. Usually they were confined to statistics of the number of farms or holdings, the acreage and yield of crops and the number of live stock. An agricultural census is more comprehensive. Its object is to obtain a complete return of the production from agricultural land, and of the power—human, animal or mechanical—employed in the production.

GREAT BRITAIN

In Great Britain an agricultural census was first taken in connection with the Census of Production Act, 1906. Under this act compulsory powers were given to the Board of Trade to obtain returns of the output of all industries, but agriculture was expressly excluded, mainly on the ground that much of the information relating to that industry was already obtained annually under a long-established system of voluntary returns from all occupiers of farms. On Nov. 23, 1907, the Board of Trade addressed a communication to the Board (now the Ministry) of Agriculture stating that for the purposes of the census of production schedules issued by them would be required to be filled up by manufacturers and other industrialists, but in the case of the produce of agriculture it was proposed to leave the collection of the necessary information to the agricultural department. The Board of Agriculture acquiesced and proceeded to issue a series of enquiries designed to supplement and complete the information obtained by the annual agricultural returns.

Census of 1908.—The results of the census taken in 1908 were published under the title of "The Agricultural Output of Great Britain," described as a "Report on enquiries made by the Board of Agriculture and Fisheries in connection with the Census of Production Act, 1906, relating to the total output of agricultural land, the number of persons engaged and the motive power employed." The "output" from agricultural land is not the same as the production. It is evident that crops produced and consumed

by live stock would be reckoned twice if their total bulk were added to the beef, mutton and pig-meat produced. Such crops are of the nature of raw materials used in the process of manufacture. The object therefore was to calculate the net production or "output," being, in fact, that part of the gross production which is sold off the farms. The total value of the crops grown in 1908 was calculated (at market prices) at £125,000,000, of which £46,600,000 represented the portion actually sold. The actual value, or, as it is termed, the "consuming value" of the major portion of the crops was thus dependent on their realization in other forms.

The total sales, *i.e.*, the "output" from all the farms, were:

England and Wales	£ 127,650,000
Scotland	23,150,000
Great Britain	150,800,000

The permanent labour employed throughout the year on the farms of Great Britain, excluding the occupiers themselves but including members of their families, was 1,173,000 persons. Consequently the gross output per person employed was £129. On the total area included in the agricultural returns the gross output amounted to £3 3s. 1d. per acre but the range was very wide on different classes of land. Thus the return from woodland was only about 6s. and from rough grazings not more than 10s. or 12s. per acre. On the cultivated area, *i.e.*, the farmed land proper, the average output was £4 10s. per acre. The mechanical motive power used on farms was generated by 34,450 engines of various descriptions with a total horsepower of 213,525.

Census of 1925.—It was intended that an agricultural census should be taken, with the census of production, quinquennially, and in 1913 the Board of Agriculture again made detailed enquiries on similar lines to those made in 1908. But before the returns could be fully tabulated and analysed the outbreak of war interrupted the work and compelled the transfer of the staff engaged upon it to more urgent matters. It was not until twelve years later that it became possible to resume the enquiries under the Census of Production Act, and as on the previous occasions the agricultural census was undertaken by the agricultural departments. The establishment, in the interval, of the Board of Agriculture for Scotland left the English department responsible only for England and Wales. The result of their enquiries was published early in 1927 under the title of "The Agricultural Output of England and Wales, 1925" (Cmd. 2815), and described as a "Report on certain Statistical Enquiries made in connection with the Census of Production Act, 1906, relating to the output of all kinds of agricultural produce and to the agricultural industry generally, together with a brief survey of agricultural statistics up to 1925."

The scope of the report was wider than that relating to 1908 not only by the inclusion of serial tables for a number of years where the materials were available, but also by an endeavour to meet a desire expressed in the House of Commons during the years 1925 and 1926 for a complete survey of the agricultural conditions and possibilities of the country. An attempt was made to meet that demand on the statistical side, it being admitted that "there are necessary limitations to the information which can be supplied by agricultural statistics and also to the deductions which can safely be drawn from them."

The value of the total output from all farms in England and Wales in 1925 was £225,330,000. The following table gives the comparative figures for each of the main groups of products in 1908 and 1925 with the percentage increase in each case:

	Thousands of £.		Percentage increase.
	1908	1925	
Live stock	50,800	78,970	55
Dairy produce	25,500	57,600	126
Poultry and eggs	4,350	15,080	247
Wool	2,100	3,000	43
Farm crops and vegetables	40,200	54,450	35
Fruit, flowers, etc.	4,200	10,230	293
Annual Totals	127,150	225,330	77

The average increase of prices in 1925 over 1908 was calculated at 77%, so that it would appear that the output was practically the same in each year although the area of agricultural land had been reduced in the interval.

Of the total output in 1925 live stock and live stock produce represented 68.6%, farm crops 20.5%, and fruit, vegetables, flowers, etc., 10.9%. Sales of fat cattle, sheep and pigs—excluding transactions in store stock between one farmer and another—represented 35%, and sales of dairy produce 25.6% of the total sales. Poultry and eggs, the output of which increased since 1913 to a greater extent than that of any other kind of produce, represented 6.7%, and wool 1.3%. Corn crops accounted for no more than 10.7%, and potatoes for 5.3% of the total. Of the corn sold about one-half in value was wheat.

Strictly speaking the output of farms is meat-animals and not meat itself in its consumable form. But, following the precedent set in the 1908 report, a calculation of the quantity of meat represented by the animals sold annually off the farms was included in the 1925 report. The average number of each kind of meat-animal slaughtered annually was calculated as follows, the numbers being in thousands (000's omitted):

<i>Cattle</i>	<i>Calves</i>	<i>Sheep and lambs</i>	<i>Pigs</i>
1,225	785	5,194	3,518

The average total quantity of meat produced (in thousands of cwt.) was:

<i>Beef</i>	<i>Veal</i>	<i>Mutton and lamb</i>	<i>Pig-meat</i>	<i>Total</i>
6,866	609	2,411	5,026	14,912

There has apparently been a substantial reduction in the production of English meat. If the estimated weight of meat of all kinds is added together the total quantity has decreased since before the war by 15%. Taking into account the increase of population the supply per head of English meat fell from 55 lb. to 44 lb., a reduction of 20%. The change in the extent of the home supply varies in each kind of meat. Beef production declined by 17% and mutton and lamb by 38%, but veal increased by 30%, and the production of pig-meat remained about the same.

Of the total quantity of milk produced about four-fifths is consumed in its natural state as liquid milk. Of the remainder about three-fourths is made into butter and one-fourth into cheese. The production and disposal of milk and dairy produce in England and Wales in the year ending June 4, 1925, are shown in the following table:

	Sales off farms		Consumed in farm households		Total	
	Actual	Equivalent in milk	Actual	Equivalent in milk	Actual	Equivalent in milk
Millions of gallons						
Liquid milk	818	818	70	70	888	888
Butter	454	133	115	33½	569	166½
Cheese	481	54	21	2	502	56
	<i>Thousands of cwt.</i>		<i>Thousands of cwt.</i>		<i>Thousands of cwt.</i>	
Cream	650	6½	650	6½
	<i>Thousands of gal.</i>				<i>Thousands of gal.</i>	
Total milk	..	1,011½	..	105½	..	1,117

The cream consumed in farm households is included under liquid milk. A considerable portion of liquid milk is sold by farmers to factories and creameries where much of it is converted into butter or cheese. Consequently the amount of milk actually consumed is less, and that of butter and cheese greater, than is shown in the above table.

Returns of the motive power used on farms showed a great increase in 1925, as compared with 1908, in the number of oil or petrol engines. In 1908 there were only 6,911, but in 1925 there were 56,744. On the other hand steam engines had been reduced from 8,690 to 3,731. Electric motors increased from 146 to 700. The number of motor tractors, which were not known in 1908, in use on farms in 1925 was 16,681.

Persons Employed.—An exact calculation of the amount of manual labour employed in agriculture is not possible owing to uncertainty as to the number of persons, male and female, who are engaged only on part-time or for certain seasonal occupations (*see* AGRICULTURAL LABOURER). The report suggests that "the total number of persons employed in the agricultural and horticultural industries in 1925 was in the neighbourhood of 800,000 which, with about 300,000 employers or persons working on their own account, gives a total of 1,100,000 engaged in the industry." On the basis of these figures it is calculated that the average output per person employed was £282, while if employers working on their own account are included the average is £205.

No official returns of the rent of agricultural land had previously been collected, but in connection with the agricultural census of 1925 estimates were obtained from the crop reporters of the average rents of holdings of various types. The average for all holdings, omitting those devoted solely to fruit, vegetables or poultry, was 31s. per acre. For arable holdings the average was 26s., for pasture holdings 36s., and for mixed holdings 29s. per acre. Classified according to size-groups, rents averaged 62s. per acre for holdings of 1 to 5 acres and 51s. for holdings of 5 to 20 acres, declining progressively to 24s. for holdings of 300 to 500 acres and 20s. for holdings of over 500 acres. The gross rental value of all farms was calculated at £43,350,000, and the gross capital value of all agricultural land at £815,000,000. The total amount of tenants' capital, including the value of live and dead stock, the tenant right valuation and other working capital was estimated at £365,000,000. (R. H. R.)

THE UNITED STATES

The first satisfactory census of agriculture in the United States was taken in 1850. Beginning with this date, the farm census, covering a gradually increasing number of items, has been taken in

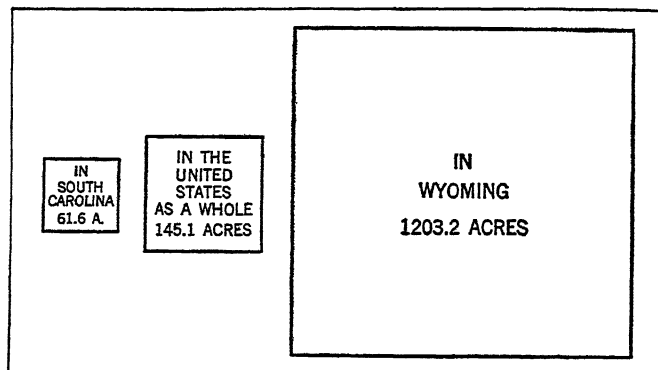

LAND AREA OF THE UNITED STATES AND FARM ACREAGE, 1850-1925
The entire column represents the total land area of the country. The lowest sub-division of each column represents the "improved" land and the division next above, the "unimproved" land

connection with each decennial census of population up to and including 1920. In 1925 was taken the first quinquennial, or inter-decennial, census of agriculture. This census was considerably less extensive in scope than recent decennial censuses have been, and it is intended to maintain this relationship; that is, to take a complete census of agriculture in the decennial year and a census covering only the more important items in the middle of the decade.

In 1850, 1,449,073 farms were enumerated in continental United States; in 1910, 6,361,502; in 1920, 6,448,343; in 1925, 6,371,640,

this census showing the first recorded decline. The census of agriculture, like the census of population, is based upon information obtained by a large force of enumerators who visit all the families in the United States, covering most of the territory within one month from the census date. The information for the census of agriculture was obtained in 1920 on a four-page standard schedule containing rather more than 400 questions. In each locality, however, there were questions that did not apply; the farmer in Maine, for example, was not asked to report cotton or oranges; and the average number of questions actually answered by the individual farmer was probably not more than 50.

AVERAGE SIZE OF FARMS IN THE UNITED STATES IN 1925 AND THE AVERAGE SIZE WITH THE SMALLEST AND THE LARGEST AVERAGE ACREAGE PER FARM

The census differs from the various estimates of crop production, live stock, etc., in that it is based upon a direct count of all the items represented, rather than upon a sample or upon calculated probabilities. The returns are carefully checked against the records of the previous census and are subjected to other forms of critical examination, so that ordinarily there is little opportunity for serious error in the count. Nevertheless the task of obtaining and tabulating reports from nearly 6,500,000 farms is one of great magnitude on the mechanical side alone. To expedite the tabulation and to facilitate the classification, the information is taken off the schedules on punched cards, one card being used for each item or group of items. The whole number of cards punched from the schedules in 1920 was 147,091,000, or about 23 cards per farm. Each of these cards went through the sorting and tabulating machines a number of times, the total amount of work of this nature amounting to the equivalent of 1,300,822,000 cards handled one time.

The information obtained in the 1920 farm census may be grouped under seven headings:

(1) **Information with Regard to the Farmer.**—The personal questions included sex, colour, age, country of birth, farm experience (that is, the number of years spent as farm labourer, farm tenant and farm owner) and number of years on present farm. The question on tenure may be considered as relating either to the farmer or to the farm, according to the point of view. The following tenures were distinguished: full owner; part owner; manager; cash tenant; share-cash tenant; standing renter (Southern States only); share tenant; cropper (Southern States only). The per cent of tenant farms in 1925 was 38.6, as compared with 38.1 in 1920; these figures indicate an almost negligible increase when compared with the rapid increase from 25.6% in 1880 to 38.1% in 1920. Considerable increases in the corn belt States just west of the Mississippi were offset by decreases in other parts of the country, mainly in a group of Eastern States centring in Ohio.

The classification of farmers by age and tenure shows that tenancy is most common in the younger groups and thus gives support to the theory of the "agricultural ladder," according to which the normal course of farm experience is for a young man to start as a farm-hand, perhaps on his father's farm, and then to become successively a farm tenant, an owner subject to mortgage and finally an owner of an unencumbered farm. The replies to a question on the 1925 schedule also indicate that a large proportion of the tenants outside the South rent their farms from close relatives,

the proportion running as high as 40% and even 50% in some counties. The social significance of tenancy under these conditions is, of course, radically different from what it would be if the relation between landlord and tenant were purely a business matter.

(2) **Farms and Farm Property.**—In addition to the total acreage of land in farms, the decennial censuses have always given the acreage of improved land; and recent censuses have also given separate figures for woodland included in farms. The census of 1925 carried a more detailed classification of farm-land, separating in particular the different types of pasture-land and showing separately crop-land idle during the preceding year and crop failure, as well as the land from which crops were harvested. The total acreage of land in farms, which increased from 293,560,614 in 1850 to 955,883,715 in 1920, declined to 924,319,352 in 1925.

Great social significance attaches to the relation between the acreage of agricultural land and the population. The changes in this relation between 1850 and 1920 are shown in the following table:

Relation between Population and Acreage of Improved Farm-land in the United States, 1850 to 1920

Census year	Population	Improved farm-land (acres)	Population per 1,000 acres of improved farm-land	Acreage of improved farm-land per capita
1920 . .	105,710,620	503,073,007	210	4.76
1910 . .	91,972,266	478,451,750	192	5.20
1900 . .	75,994,575	414,498,487	183	5.45
1890 . .	62,947,714	357,616,755	176	5.68
1880 . .	50,155,783	284,771,042	176	5.68
1870 . .	38,558,371	188,921,099	204	4.90
1860 . .	31,443,321	163,110,720	193	5.19
1850 . .	23,191,876	113,032,614	205	4.87

The improved acreage probably measures the extent of productive farm-land more accurately than does the total acreage, which includes large areas of woodland and of land useful only for grazing. The number of acres of improved land per capita was only a little less in 1920 than in 1850, indicating that the growth of the agricultural area had about kept pace with the growth of the population.

The census of 1925 shows a slight decrease in the farm acreage, but since 1920 several new factors, including the extensive replacement of farm work stock (which was a consumer of farm products) by motor equipment, have tended to keep farm production ahead of the growth in population and even to create a surplus. The value of farm property shown in the census reports includes not only the value of the farm real estate, with separate figures for the value of buildings, but also the value of implements and machinery and of live stock. The aggregate value, after increasing from \$20,440,000,000 in 1900 to \$77,924,000,000 in 1920, declined to \$57,018,000,000 in 1925, mainly by reason of a lower price level. Data as to mortgage debt are secured only for farms operated by their owners, and the figures for the amount of debt are shown only for what are termed full owners; that is, farmers who own all the land that they operate. The reports of the census of 1920 show the rate of interest paid on the farm mortgage debt as well as the amount of debt on farms in different groups classified according to value.

(3) **Live Stock.**—The live-stock inventory, as obtained at the various decennial censuses, has shown an increasing amount of detail in the classification. It has been found desirable not only to report separately the calves, lambs, colts, etc., as representing a new generation of live stock just coming into existence, but also to make other age classifications, separating, for example, horses and cattle between one and two years old from those two years old and over. Sex classifications are also required. Recent censuses have attempted to separate dairy cattle from beef cattle, though the results so far obtained have not been absolutely satisfactory, mainly because of the difficulty of classifying general-purpose cattle.

(4) **Crops.**—Perhaps the simplest and most fundamental item in the farm census, after the number and acreage of farms, is the acreage of the more important crops harvested in the year preceding the date of the census enumeration. The census schedules call both for the number of acres harvested and for the quantity of the product. Previous to 1920 each farmer was asked to state also the value of his product. Beginning with 1920 the average value per bushel or other unit of measure has been obtained independently for most of the crops, and the value has been computed for the total production of each county.

The cotton crop receives special attention. Its acreage and production are reported along with other crops in the returns of the decennial or quinquennial censuses. In addition reports of production are secured every year from the ginner of cotton. These reports are received (and published) semi-monthly during the major part of the ginning season, and the total production of cotton, as reported by the ginner, is available to the public shortly after the harvest is completed. The cotton-ginning reports probably represent the most accurate statistics of crop production that are available for any crop on a large scale anywhere in the world.

(5) **Live-stock Products.**—The live-stock products reported in the census comprise wool and mohair, eggs and chickens and dairy products, including the total production of milk, the production and sales of butter, and the sales of milk, cream and butter-fat. Some difficulty is experienced in obtaining accurate reports from the farmers as to the total production of milk, except in cases where practically the whole amount is sold. The proposal that this question be omitted from the schedule by reason of this difficulty meets with instant objection, however, from those who use the statistics of the dairy industry. In connection with live-stock products, the census bureau makes practically the only estimates—as distinguished from enumerations—which appear in its decennial reports. A considerable number of farmers report the number of sheep which they had on the census date but fail to report the wool production; other farmers likewise report chickens but no eggs, or dairy cows but no milk. For the farms failing to report production, estimates are made on the basis of the average production per unit as shown by the complete reports.

(6) **Miscellaneous Items.**—Data for farmers' expenditures for feeding stuff, fertilizers and labour have been obtained as a part of the farm census for several decades. In 1920 new items were introduced, including the number of tractors and automobiles on farms, the number of farm houses equipped with running water or with electric or gas lights, and the number of farms having telephones. In 1925 the tractor item was continued, a question as to radio sets was asked, and a query was added as to the kind of road on which the farm was located.

THE NUMBER IN EACH 100 FARMS IN THE UNITED STATES SUB-DIVIDED BY THE CHARACTER OF ROADS UPON WHICH THEY ARE SITUATED

(7) **The Farm Population.**—The farm population, as distinct from the total rural population, was reported for the first time in the population census of 1920. Farm population figures were also secured in the farm census of 1925. Under the definition employed in 1920, farm labourers not living on a farm but living in strictly rural territory, outside any incorporated place, were included with the farm population. In 1925 the enumeration was necessarily limited to those persons living on farms, since the canvass covered only the farms. Estimating and deducting from the 1920 totals the non-farm-resident farm labourers, it appears that the farm resident population of the United States decreased from about 31,000,000 in 1920 to about 29,000,000 in 1925, or an average an-

nual decrease of 400,000. During the same years the total population of the country was increasing at the rate of about 1,800,000 per year, so that while the farm population was decreasing at the rate indicated, the non-farm population was increasing at the rate of 2,200,000 per year.

The census statistics thus indicate the current trend, not only in such material elements as acres of land, bushels of wheat and thousands of cattle and hogs, but also in the more important element consisting of the people who make their homes on the nearly 6,500,000 farms in the United States and depend for their livelihood mainly on the products of agriculture. (L. E. T.)

AGRICULTURE, CHAMBERS OF. The Central Chamber of Agriculture in Great Britain was founded in 1866 simultaneously with the formation of local chambers in the country. These were combined into one association, known as the Central and Associated Chambers of Agriculture. The objects of the Association are to promote the interests of agriculture, and with that view to watch over all measures affecting agriculture both in and out of parliament, and to take such action thereon as may seem desirable in its interests. The scope of the association has widened, and it now comprises not only chambers and farmers' clubs, but agricultural societies, unions, federations, dairy associations and other agricultural institutions. Its aim is to form a common centre for all the different sections and groups in the industry. The work of the chamber is governed by a council of twenty-four members chosen by the subscribing members of the central chamber, and about 70 deputies appointed annually by the various federated bodies.

AGRICULTURE, PRIMITIVE. Agriculture (cultivation or tillage of the ground for the production of plants for food) is the basis of civilization, and primitive agriculture marks the transition from the lowest cultural stage, commonly called savagery. When and where, how and why were the first steps taken? No simple answer can be given. As to the date and place, a few hints are given by archaeology, but where primitive agriculture is now established there is rarely even a tradition of its origin. "God Almighty first planted a garden" is the general belief, God being represented by Osiris in Egypt, King Kintu in Uganda, Sidi or Soidi in Torres Strait, Ofanu in Tahiti, Tupan in Brazil, and by all the other local culture-heroes who brought the good gifts to men. As to the how and the why, information must be sought in areas where beginnings are being made. There is as yet no cultivation of the soil or raising of crops in the Arctic regions, in the semi-desert regions of north and south Africa and Arabia, in the prairies of North America, the steppes of Asia, the high plateaux of Tibet and Mongolia, or the whole of central Australia. It is unknown also in certain jungle areas inhabited by groups of pygmy peoples, such as the Negrilloes of the Congo, the Andamanese, the Semang of the Malay peninsula, and there is no record of it among the extinct Tasmanians.

The first steps have been noted in various parts of the world. In Western Australia a species of flag was cultivated to the extent of burning down the crop at the end of the season to improve the next crop. Also, when digging up yams, the natives replaced the heads in the holes. Purslane (*Portulaca*) was also encouraged if not artificially cultivated. The Besisi of the Malay peninsula used to carry fruit they were eating to fresh spots so that the seeds might spread over the country. In Arizona a company of Cocopa, Mohave or Pima women, safely guarded by a number of men, set forth to a rich and favourable spot on the side of a cañon. Each woman has a little bag of gourd seed, and she plants these, one by

one, in rich crannies or crevices where the roots can find sustenance, the sun may shine in, and the fruit may later swing down, as from a trellis. The planters go home and take no further notice of their vines until they return in the autumn to collect the gourds. In manioc areas, the natural means of procuring food is still by hunting. Cassava forms a useful alternative, and when game is scarce or hunting unsuccessful, manioc culture increases in importance, yams, beans, peas, pumpkins and maize being added to the crops, while if hunting fails altogether, the group perforce turns to agriculture. Examples are common in the Congo region. Similarly compulsion turns pastors into agriculturalists. In Africa the women have no share in cattle tending and are often mainly occupied in cultivating the crops of maize and vegetables. Should war or disease cause the herds to dwindle, or encroachments diminish the extent of the pasturage, the necessity for agriculture is increased until it absorbs the whole community. Sometimes the stimulus is given by political pressure, as in the case of the Bashkir Tatars, whose pasture lands were encroached upon by Russians to the north and west, and by the Ural Cossacks to the east, so that they could no longer support flocks and herds in sufficient numbers. Sometimes, however, although the first steps are taken, progress goes no farther, as in the wild rice districts of North America in the neighbourhood of the Great Lakes. Most of the Indians who had access to the rice fields collected the rice, ate it at every meal until it was finished, and then turned to other sources of food. There was a common belief that if any seed were sown no more would ever grow wild, and while food was plentiful and space and game were abundant, no further steps were taken.

Assartage.—In tropical or semi-tropical countries the common method of agriculture is assartage or essartage (from Lat. *exsartare*, to grub up trees and bushes from forest land to make it arable). For example, in South America a tract of specially productive forest land is chosen as a site for a maize field, smaller trees and undergrowth are cut down at the end of the rainy season, except those of greater size or of very hard wood, and the fallen masses, dried by sun and air for a few weeks, are then fired. On this charred surface, among half-burnt branches and blackened trunks, the maize is planted in holes a few feet apart, and when it reaches the surface the Indian clears and stirs the ground with the hoe. Immediately after harvest the ground is prepared for a fresh crop, which, however, yields much less, and the clearing is then abandoned for several years. It soon becomes overgrown with weeds and undergrowth, and after a time, if no virgin land can be had, these will be burnt down and the land replanted as before; but the crops are poor, the soil is exhausted, the ashes of the undergrowth have not sufficient fertilizing value, and the clearing is finally abandoned. The burning of the felled trees enriches the land, and the same clearing can be used two, three or more times, but is less and less productive each season, so that new land is prepared and the cropped piece left fallow. The system is practised wherever space permits.

In Torres Strait each family has its patch of garden land marked out within the tribal area by definite boundaries. The limit may be marked by standing trees but more commonly the boundary is a ridge of earth, formed by the weeds and refuse thrown on the edge in the process of clearing the land. Every year a man clears a new piece of land and lets another portion lie fallow. The men cut down the larger trees, formerly with shell axes, while the women attack the undergrowth. There is no regular rotation of crops; usually the same plants (yams, bananas, sweet potatoes or sugar-cane) are planted in the same patch; only, as the crops deteriorate after one, two or three years, the land is allowed to lie fallow until the undergrowth is four or five years old, when it is cleared again. There are special names for gardens of successive ages. A newly cleared patch is *kerkar gedub* (new garden), next year it is *keas gedub*, and after two years *gazag gedub*. *Keas* and *gazag* gardens are not replanted, though sugar-cane and bananas continue to bear. (Torres Strait Reports, iv. 145-151.) Extensive agriculture (clearing a fresh patch every season) may go on as long as there is sufficient land, either virgin land still uncleared or overgrown fallow worth clearing; but where, owing to limitations of land or increase of population or

other economic influences, more crops or better crops are required and the exhausted land cannot restore itself, artificial restoration must be applied. Extensive agriculture becomes intensive.

Agriculture is everywhere associated with magic and religious ceremonies to ensure fertility, but artificial fertilization of a more practical nature is not unknown to primitive gardeners. Mariner describes it in Tonga in 1827; powdered pumice was used in the Gilbert isles; human manure was a marketable commodity in Mexico, as in China. In America artificial manuring was found from Nova Scotia to Chile. Fish was commonly planted in the mounds with the maize seed and guano was carefully collected. In Peru extensive cultivation was impossible from lack of space, and crops were restricted to the pockets (*bolson*) of rich soil, consisting of detritus washed down by the mountain torrents, enriched with mineral deposits from volcanic rocks. These natural plots were enlarged by irrigation streams which were also fertilizing. The guano beds of Peru were highly valued; they were the property of the different provinces, and the breeding places of the birds were protected by law.

Irrigation.—Leading an artificial stream on to a patch of land, to provide water for a crop varies from the hollowed tree-fern trunk which the Fijian lays down to supply his taro bed, to the imposing engineering works of the primitive agriculturalists of Peru, or the miles of aqueducts of ancient Ceylon. The sources of water may be natural rivers or lakes, artificial canals, reservoirs or underground supplies, and there are many contrivances for directing it over the land to be watered. Water from a higher level is led off in narrow mud-banked channels which can be stopped or diverted merely by blocking up or breaking down a channel wall here and there. If the water has to be raised, a man may sit by the side of a stream with a half gourd or coco-nut (nowadays often a kerosene tin) fixed to a stick, ladling out the water and pouring it on to his crop. In deep water a bucket is lowered by means of a rope and drawn up to the surface. The *shaduf*, characteristic of Egypt, and widely distributed from West Africa to the East Indies, consists of a forked pole stuck in the ground, with a long pole balancing on the fork, its heavier end on the bank, and the lighter end, with a bucket attached, over the water. The bucket is lowered into the water, and, when full, the heavy end of the pole helps to raise it. Water can thus be raised 10 or 15ft., and a succession of *shadufs* can raise it to any height required. When there is running water, a water-wheel with buckets on an endless chain is common in the Old World, or the wheel may be turned by animals or men. Where the underground supply of water is very deep, as in parts of India or in the Sahara, a pit is dug, walled in with masonry, and a skin bag lowered over a pulley by long ropes to a depth of 100 or 200ft. The ends of the ropes are attached to bullocks, mules, donkeys, camels, women or slaves, who walk down a slope equal to the depth of the wall. Neither the *shaduf*, the water-wheel or the pulley was used in the New World, but there are extensive irrigation works in the drier Pueblo region, especially Arizona, where 150 miles of ancient irrigation ditches may be traced. In Mexico and Peru extensive engineering works prove the care given to irrigation. Channels were carried round the sides of mountains and even tunnelled through them; so that the waters of the higher valleys where the supply was abundant were made available for the cultivation of others where it was deficient; and these channels were made to irrigate not only the cultivated fields but the llama pastures on the mountain sides.

Terrace Cultivation.—In clearing the land for planting, the trees are felled, the stones are collected or undergrowth and weeds heaped up all along the edges of the space to be planted, and ridges and terraces are thus formed. The discovery of their value for preserving moisture and preventing erosion on slopes would easily lead to the artificial terracing so widely distributed throughout the Old and New Worlds. Terrace cultivation is imposed on agriculture by political, geographical, climatic or economic influences. An agricultural group is by its nature exposed to attacks which, by its nature, it is unable to resist except by retreat to a naturally fortified or easily defended position; and this is provided by the hills, where every patch must be carefully preserved and augmented. Artificial banks are therefore raised to prevent

further erosion, and, if necessary, loads of earth are retrieved from the valleys. Such is the precarious agriculture of the Man Tze, or "untameable worms," as the aboriginal inhabitants are called by their Mongol conquerors who forced them to retreat into the mountain fastnesses of the Yangtse valley, where, at a height of about 10,000ft. above sea-level, they perch their villages on the steep cliffs. The back of the house is burrowed out of the rock face; the front is supported on a platform, resting on beams; the approach is by steps made of bolts driven into the rock, and small children are tethered to the door-posts to prevent them from falling over the edge. Here in little patches between the rocks every inch of soil is carefully tilled and crops are raised though the only

access to the terrace may be by a rope (I. B. Bishop, *The Yangtse Valley and Beyond*, 1900). Both archaeology and history show evidence of early terracing round the Mediterranean and in Britain during the Bronze Age.

In hilly and mountainous districts where the rainfall is insufficient or irregular, terrace cultivation and irrigation go hand in hand. The water from a mountain stream is easily directed down

A PRIMITIVE EGYPTIAN RAKE OF THE XXth DYNASTY FOUND AT LISHT

the slope, and the embankments of the terraces preserve the moisture, so this method is universal on the drier slopes throughout the world. The Arabs in Yemen give the best example. Here the mountains are terraced from their base up to sometimes as high as 6,000ft., with terrace walls from 5ft. to 15ft. high. Reservoirs filled in the two rainy seasons supply the streams for the irrigation channels. When, in the 10th century, the Arabs reached Spain, they converted every mountain slope into a succession of green terraces. In the mountain areas of India, in Ceylon, in Tibet and in China, terrace cultivation can be seen on a large scale. The Chinese, farmers of 40 centuries, carry terracing to a fine art. In densely populated neighbourhoods every inch of soil is of value; it is collected in baskets in the valleys, carried up the barren hill slopes, and embanked, forming astonishingly productive gardens. Examples are rare in the New World, but in Peru the same necessities were met by the same device, and hundreds of terraces one above the other rose from the valleys to the utmost cultivable limit. These were extended year by year by communal labour, and produced the finest crops of potatoes and maize, eliciting the astonished admiration of Cortes: "There was not a span that was not cultivated." Increase of population and of civilized wants, with the growing importance of food-crops or drink-crops, lead to the intensive cultivation seen in the mountain zone of Europe; in Switzerland, for example, or the Moselle and Rhine valleys, in the Vosges and Black Forest, in the Subian Jura, in Italy, up the slopes of the Apennines or the Ligurian Alps, and in the "desperate agriculture" of Teneriffe, where camels laden with earth bring soil for the gardens almost daily into the town of Santa Cruz.

Implements.—The primitive implement is everywhere the digging stick, usually merely a strong stick, with one end pointed or flattened (a rudimentary spade) and often hardened in the fire. This is used for digging up roots by people who do not cultivate the soil, such as the Australians or the Bushmen of South Africa. The Bushmen weight their digging sticks with a heavy perforated stone whorl which acts as a lever. The digging stick or *δ* in use in Tahiti nearly a century ago was originally a stick sharpened at the point and hardened by charring at the end; but when iron was obtainable, a narrow sharp piece like a chisel was fixed at the end, and as much of the ground was stony, this was found very convenient. No use was made of the foot in thrusting the spade into the soil, but the digger assumed a crouching attitude, piercing the ground and breaking up the earth by the strength of hands and arms (Ellis, *Polynesian Researches*, p. 137-138). In Fiji the grass, reeds and undergrowth were broken down by a sharp-edged club. The digging sticks (poles with one end flattened) are used by three or four men encircling a large clod which they lever up. The women, fol-

lowing on their knees, pulverize this with their hands. A hoe, made of turtle shell or an oyster valve, was used for weeding. A knife has now replaced the club, but as a spade is painful to bare feet, the digging stick holds its place, though its power is now increased by an iron blade. In New Zealand the Maori lashed on a foot-piece at right angles to the digging stick; in Peru a foot-rest is bound on with leathern thongs, and, higher up, another rest is attached in the same way; this is for the left hand, which assists the foot in applying the weight of the body to the thrust. Similar types are found from New Mexico to Chile. The *caschrom*, still used in the stony patches of the Shetlands and the Hebrides, is a larger and more elaborate digging stick, with its end shod in iron and a foot-rest attached. The hoe is really a pick, with the digging end flattened. The simplest form is a piece of wood, with a natural angle, usually part of the trunk and a projecting branch, or two pieces of wood fastened together. The former is illustrated in Europe in the Swedish "hack" and the latter was characteristic of ancient Egypt. In North America a bent piece of wood, the shoulder blade of elk or bison, or a piece of tortoise shell is fastened to a handle, but the hoe was rare in America except in the eastern maize area. The African hoes are of iron, often set at an acute angle to the shaft, this and the shortness of the handle necessitating a crouching position when hoeing. The size and shape of the hoes in Nigeria reflect the variation of soil, a gradation being traced from the sandy soils of the north to the heavier land of the south.

A STONE SICKLE OF THE TYPE USED IN EGYPT 4,000 YEARS AGO RECONSTRUCTED FROM FRAGMENTS DISCOVERED AT THEBES

There can be little doubt that women were the earliest agriculturalists. Even when the harder labour of clearing the ground is done by men, planting, sowing, tending and collecting are still women's work. "When the women plant maize," say the Indians, "the stalk produces two or three ears. Why? Because women know how to produce children. They only know how to plant corn to ensure its germinating. Then let them plant it. They know more than we do." (Payne, *History of the New World*, ii. 7.) It is therefore easy to guess that the cultivation of plants was one of women's contributions to the development of civilization; and it is quite in harmony with this conjecture that the cereal deities are usually female, both in the Old World and in the New.

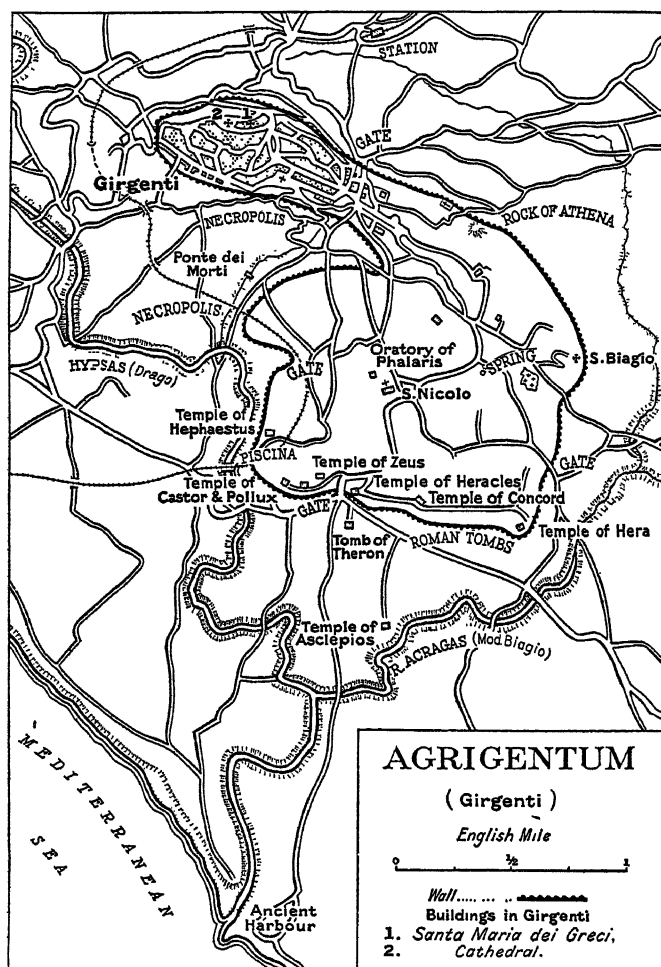

See O. T. Mason, *The Origins of Invention* (1895); E. J. Payne, *History of the New World called America* (1895); E. C. Semple, *Influence of Geographical Environment* (1911). (A. H. Q.)

AGRICULTURE, TROPICAL: see TROPICAL AGRICULTURE.

AGRI DECUMATES, "tithe lands" given by the Romans to Gallic settlers, and also to Roman veterans on the payment of a rent of a tenth (*decuma*) of the produce, on the east of the Rhine. (See LIMES GERMANICUS.)

AGRIGENTUM (Gr. *Ἀκράγας*, mod. AGRIGENTO), ancient city, south coast of Sicily, 2½ m. from the sea. Founded by Greek colonists from Gela as late as 582 B.C., its favourable site for cultivation and trade with Carthage made it second only to Syracuse. Pindar calls it *καλλίστα βροτέων πόλιων* (fairest of mortal cities). Ruled at first by tyrants, in 472 a democracy was established. In the struggle between Syracuse and Athens (415-413) the city remained neutral. Its prosperity continued to increase (its population is given at over 200,000) until in 405 B.C. it was captured and plundered by the Carthaginians, a blow from which it never entirely recovered. It was colonized by Timoleon in 338 B.C. with settlers from Velia in Lucania, and in the time of the tyrant Phintias (289-279) it had regained some of its power. In the first Punic War, however, it was sacked by the Romans (261) and the Carthaginians (255), and finally in the

second Punic War by the Romans (210). Still in the Roman period, it exported agricultural products, textile fabrics and sulphur. In the local museum are tiles used for stamping cakes of sulphur, which show that the mines, at any rate from the 3rd century A.D., were imperial property leased to contractors. The site is unusual and beautiful with a lofty ridge with two summits to the north. On the western summit is the modern town (985ft.), the eastern summit slightly higher, bears the name of Rock of Athena, owing to its identification by some scholars with the acropolis of Acragas as described by Polybius, who places upon it the temple of Zeus Atabyrius (said to have been erected by the half-mythical Phalaris) and that of Athena. The available space about 70 x 20 yds. on the eastern summit is, however, too small. In the modern town, on the other hand, the remains of one temple are to be seen in the church of Sta. Maria dei Greci, while the other is generally supposed to have occupied the site of the cathedral. On the north both summits are defended by cliffs; on the south the ground slopes away somewhat abruptly from the eastern summit towards the plateau on which the town stood, while the western summit is separated from this plateau by a valley traversed by a branch of the Hypsas (mod. *Drago*), the deep ravine of which forms the western boundary and defence of the city. On the east is the valley of the Acragas (Fiume S. Biagio). The church of S. Biagio, above it, is built into the temple of Demeter which was preceded by a sanctuary in the cliffs. The Acragas defends the approach from the east and the

deeper Hypsas that from the south-west. They unite south of the town and flow out in the small abandoned harbour. A row of important Doric temples crowns the southern slopes; they are built of the local porous stone, which is of a warm red brown colour, full of fossil shells and easily corroded when exposed to the air. Of all these temples the oldest is probably that of Heracles (eight columns of which have recently been re-erected).

*Dimensions in English feet.

while the best preserved are those wrongly attributed to Hera and Concordia, which are very similar in dimensions; the latter, indeed, lacks nothing but its roof, owing its preservation to its conversion into the cathedral in 597 by Gregory II., bishop of Girgenti. These temples are among the finest in existence. In front of the former, as in front of those of Heracles and Zeus, stood a huge altar for burnt offerings, as long as the façade of the temple itself. The *cella* of the temple of Heracles was modified in Roman times, and a statue of Asclepius seems to show change of cult.

In the colossal temple of Zeus the huge Atlantes (figures of Atlas), 25ft. in height, are noticeable. They seem to have stood in the inter-columniations half-way up the outside wall and to have supported the epistyle. The collapse both of this temple and of that of Heracles must be attributed to an earthquake; many fallen blocks of the former were removed in 1756 for the construction of the harbour of Porto Empedocle. The four columns

THE TEMPLE HERE SHOWN WITH ALL ITS COLUMNS STILL IN SITU, WHICH HAS BEEN WRONGLY ATTRIBUTED TO CONCORDIA, IS THE BEST PRESERVED OF THE NUMEROUS AND SPLENDID RUINS STILL TO BE FOUND ON THE SITE OF THE CITY OF AGRIGENTUM. IT OWES ITS PRESERVATION TO GREGORY II. BISHOP OF GIRGENTI

erected on the site of the temple of Castor and Pollux are a modern (and incorrect) restoration in which portions of two buildings have been used. Of that of Hephaestus only two columns remain, while that of Asclepius, a mile to the south of the town, an anta and two pillars are preserved. Other remains are unimportant. Near the picturesque church of S. Nicolo is the so-called oratory of Phalaris, a tomb of the 1st century B.C., 27½ft. by 23½ft., and not far off on the east are two private houses of the Roman period. The fishpond (circumference said by Diodorus to be 7 stadia) is an enormous excavation south-

west of the city, with drains in its sides; the bottom is now an orange garden.

The wall line can be traced, but actual remains are small except in the valley below the temple of Demeter (S. Biagio). East and west ravines gave protection, so a massive wall was unnecessary, while near the south-east angle a breastwork was formed by the excavation of the natural rock, in later times honeycombed with tombs. Close to this temple on the west is the site of the gate known in later times as the *Porta Aurea*, through which the modern road passes.

Tombs of the Greek period have been found mainly on the west of the town, outside the probable line of the walls, between the Hypsas and a small tributary, the latter having been spanned by a bridge, now called *Ponte dei Morti*, of which one massive pier, 45ft. in width, still exists. Just inside the south wall is a Christian catacomb, and outside it a tomb in two storeys, a mixture of Doric and Ionic architecture, belonging probably to the 2nd century B.C. A village of the Byzantine period has been explored at Balatizzo, immediately to the south of the modern town. The walls of the dwellings are entirely cut out of the natural rock.

The modern town, known as Girgenti till 1928 but now reverting to an older form of its name, is the capital of the province of Agrigento, and an episcopal see, 58 m. S. by E. of Palermo direct and 84½ m. by rail. Pop. (1921) 23,712 (town), 29,823 (commune). The cathedral occupies the highest point in the town; it was founded in the 13th century and there are other remains of architecture of this period. The museum contains fine vases, terra cottas, sculptures, etc. Porto Empedocle (pop. 1921, 11,743) 5½ m. S. by rail, is connected with Castelvetro, on the line from Palermo to Trapani. It is the principal port for the shipment of sulphur, the mining district beginning just north of Agrigento.

See J. Schubring, *Historische Topographie von Akragas* (1870). (T. A.)

AGRIMONY, a slender perennial herb (botanical name, *Agrimonia Eupatoria*, family Rosaceae), 1½ to 3ft. high growing in hedge-banks, copses and borders of fields. The leafy stem ends in spikes of small yellow flowers. The flower-stalk becomes recurved in the fruiting stage, and the fruit bears a number of hooks which enable it to cling to rough objects, such as the coat of an animal, thus ensuring distribution of the seed. The plant is common in Britain and widely spread through the north temperate region. The underground woody stem is astringent and yields a yellow dye.

The name has been unsystematically given to several other plants; for instance: bastard, Dutch, hemp or water agrimony (*Eupatorium cannabinum*); noble or three-leaved agrimony (*Anemone Hepatica*); water agrimony (*Bidens*); and wild agrimony (*Potentilla Anserina*).

AGRIOLGY is the science of the prehistoric human practices and ways of living, especially those pertaining to the key-factors of existence, food, shelter and clothing.

AGRIONIA, an ancient Greek festival, celebrated annually at Orchomenus in Boeotia and elsewhere, in honour of Dionysus Agrionius ("the wild") by women and priests at night. The tradition is that the daughters of Minyas, king of Orchomenus, having despised the rites of the god, were seized with frenzy and ate the flesh of one of their children. At this festival it was originally the custom for the priest of the god to pursue a woman of the Minyan family with a drawn sword and kill her. (Plutarch, *Quaest. Rom.* cii., *Quaest. Graecae*, xxxviii.)

AGRIPPA, a sceptical philosopher, whose date cannot be accurately determined. He must have lived later than Aenesidemus. To him are ascribed the five tropes (*πέντε τρόποι*) which, according to Sextus Empiricus, summarize the attitude of the later ancient sceptics. (1) Since some thinkers hold that nothing is known but the sensible; others that nothing is known but the intelligible, it follows that the only wise course is neither to affirm nor to deny. (2) The proof of one so-called fact depends on another fact which itself needs demonstration, and so on *ad infinitum*. (3) The data of sense are relative to the sentient being, those of reason to the intelligent mind; that in different conditions things themselves are seen or thought to be different. Where, then, is the absolute criterion? (4) All knowledge depends on certain hypotheses, or facts taken for granted. Such knowledge is hypothetical. (5) The fifth trope points out the impossibility of proving the sensible by the intelligible inasmuch as it remains to establish the intelligible in its turn by the sensible. Such a process is a vicious circle and has no logical validity. A comparison of these tropes with the ten tropes enumerated in the article *AENESIDEMUS* shows that scepticism has made an advance into the more abstruse questions of metaphysics. The first and the third include all the ideas expressed in the ten tropes, and the other three systematize the more profound difficulties which new thinkers had developed.

See Diogenes Laertius x. 88, and Zeller's *Greek Philosophy*. Also the articles *SEPTICISM*; *AENESIDEMUS*.

AGRIPPA, HEROD I. (c. 10 B.C.—A.D. 44), king of Judaea, the son of Aristobulus and Berenice, and grandson of Herod the Great, was born about 10 B.C. His original name was Marcus Iulius Agrippa. Josephus informs us that, after the murder of his father, Herod the Great sent him to Rome to the court of Tiberius, whose son Drusus became his friend. On the death of Drusus, Agrippa, who had been recklessly extravagant, was obliged to leave Rome overwhelmed with debt. After a brief seclusion, Herod the Tetrarch, his uncle, who had married Agrippa's sister Herodias, made him *Agoranomos* (Overseer of Markets) of Tiberias, and presented him with a large sum of money; but his uncle being unwilling to continue his support, Agrippa left Judaea for Antioch and soon after returned to Rome, where he was welcomed by Tiberius and became constant companion to the emperor Gaius (Caligula), then a popular favourite. Agrippa, overheard by his freedman Eutyches to express a wish for Tiberius' death and the advancement of Gaius, was betrayed to the emperor and cast into prison. In A.D. 37 Caligula, having ascended the throne, heaped wealth and favours upon Agrippa and gave him the tetrarchy of Batanaea and Trachonitis. To this he added that held by Lysanias; and Agrippa journeyed into Judaea to take possession of his new kingdom. In A.D. 39 he returned to Rome and brought about the banishment of Herod Antipas, to whose tetrarchy he succeeded. On the assassination of Caligula (A.D. 41) Agrippa supported the emperor Claudius, who gave him the government of Judaea, while the kingdom of Chalcis in Lebanon was, at his request, given to his brother Herod. Thus Agrippa became one of the greatest princes of the east, the territory he possessed equalling in extent that held by Herod the Great. He returned to Judaea and governed it to the great satisfaction of the Jews. His zeal, private and public, for Judaism is celebrated by Josephus and the rabbis; and the narrative of Acts xii, telling of his persecution of the Apostles James and Peter, gives a typical example of it. Both the Acts of the Apostles and Josephus give an account of his sudden death after an exhibition of games at Caesarea. A

third account says that Agrippa was assassinated by the Romans, who objected to his growing power. He had shown too independent a spirit in his attempt to strengthen the walls of Jerusalem and to summon a meeting of other client princes and after his death the emperor appointed no more kings of Judaea, but ruled the province by means of procurators.

See articles Josephus, J.A. 18 and 19 in *Ency. Bibl.* (W. J. Woodhouse), *Jewish Ency.* (M. Brann), with further references; N. S. Libowitz, *Herod and Agrippa* (2nd ed., 1898); Grätz, *Geschichte d. Juden*, iii. 318–361.

AGRIPPA, HEROD II. (27–100), son of Agrippa, Herod I., and like him originally Marcus Julius Agrippa, was born about A.D. 27, and received from Claudius the tetrarchy of Chalcis and the oversight of the Temple on the death of his uncle, Herod, A.D. 48. In A.D. 53 he was deprived of that kingdom and given other provinces instead. He tried to prevent the Jews from rebelling, and when war broke out sent auxiliaries to help the Romans. He died in Rome in A.D. 100. He was the seventh and last king of the family of Herod the Great. It was before him and his sister Berenice (q.v. B.2) that St. Paul pleaded his cause at Caesarea (Acts xxvi.). He supplied Josephus with information for his history.

AGRIPPA, MARCUS VIPSANIUS (63–12 B.C.), Roman statesman and general, son-in-law and minister of the emperor Augustus, was of humble origin. He was of the same age as Octavian (as the emperor was then called), and was studying with him at Apollonia when news of Julius Caesar's assassination (44 B.C.) arrived. By his advice Octavian at once set out for Rome. Agrippa played a conspicuous part in the war against Lucius, brother of Mark Antony, which ended in the capture of Perusia (40). Two years later he put down a rising of the Aquitanians in Gaul, and crossed the Rhine to punish the aggressions of the Germans. On his return he refused a triumph but accepted the consulship (37). At this time Sextus Pompeius, with whom war was imminent, had command of the sea on the coasts of Italy. Agrippa's first care was to provide a safe harbour for his ships, which he accomplished by cutting through the strips of land which separated the Lacus Lucrinus from the sea, thus forming an outer harbour; an inner one was also made by joining the lake Averna to the Lucrinus (Dio Cassius xlviii. 40; Pliny, *Nat. Hist.* xxxvi. 24). About this time Agrippa married Pomponia, daughter of Cicero's friend Pomponius Atticus. Having been appointed naval commander-in-chief he put his crews through a course of training, until he felt in a position to meet the fleet of Pompeius. In 36 he was victorious at Mylae and Naulochus, and received the honour of a naval crown for his services. In 33 he was chosen aedile and signalized his tenure of office by effecting great improvements in the city of Rome, restoring and building aqueducts, enlarging and cleansing the sewers, and constructing baths and porticos, and laying out gardens. He also first encouraged the public exhibition of works of art. The emperor's boast that he had found the city of brick but left it of marble ("marmoream se relinquere, quan latericiam accepisset," Suet. Aug. 20), might with greater propriety have been uttered by Agrippa. He was again called away to take command of the fleet when the war with Antony broke out. The victory at Actium (31), which gave the mastery of the world to Octavian, was mainly due to Agrippa. As a token of signal regard Octavian bestowed upon him the hand of his niece Marcella (28). We must suppose that his wife Pomponia was either dead or divorced. In 27 Agrippa was consul for the third time, and in the following year the senate bestowed upon Octavian the imperial title of Augustus. Probably in commemoration of the battle of Actium, Agrippa built and dedicated the Pantheon still in existence as *La Rotonda*. The inscription on the portico states that it was erected by him during his third consulship. His friendship with Augustus seems to have been clouded by the jealousy of his brother-in-law Marcellus, which was probably fomented by the intrigues of Livia, the second wife of Augustus, who feared his influence with her husband. In 23 B.C., Agrippa went as governor to the East, ruling by means of legates, while he himself remained at Lesbos. But the death of Marcellus, which took place in the same year, obliged the emperor to look

to Agrippa as his successor. He was recalled to Rome, and to strengthen the tie between him and Augustus was made to divorce Marcella and marry the emperor's daughter Julia (21), the widow of Marcellus. In 19 he was employed in putting down a rising of the Cantabrians in Spain. In 18 B.C. he received the Tribunician power for five years, and in the following year a renewal of his command in the East, where his just and prudent administration won him the goodwill of the provincials, especially the Hebrew population. His last public service was the bloodless suppression of an insurrection in Pannonia (13). He died at Campania in March of the year following his 51st year. Augustus honoured his memory by a magnificent funeral.

Agrippa was also known as a writer, especially on geography. Under his supervision Julius Caesar's design of having a complete survey of the empire made was carried out. Amongst his writings an autobiography, now lost, is referred to. Agrippa left several children; by Pomponia, a daughter Vipsania, who became the wife of the emperor Tiberius; by Julia three sons, Gaius and Lucius Caesar (adopted by Augustus as his successors) and Agrippa Postumus, and two daughters, Agrippina the elder, afterwards the wife of Germanicus, and Julia, who married Lucius Aemilius Paullus.

See Dio Cassius xlix.-liv.; Suetonius, *Augustus*; Velleius Paterculus ii.; Josephus, *Antiq. Jud.* xv. 10, xvi. 2; Turnbull, *Three Dissertations*, one of the characters of Horace, Augustus and Agrippa (1740); Frandsen, *Marcus Vipsanius Agrippa* (1836); Motte, *Étude sur Marcus Agrippa* (1872); Nispi-Landi, *Marcus Agrippa e i suoi tempi* (1901); D. Detlefsen, *Ursprung, Einrichtung und Bedeutung der Erdkarte Agrippas* (1906); V. Gardthausen, *Augustus und seine Zeit*. Vol. i. 762 foll., ii. 432 foll.

AGRIPPA VON NETTESHEIM, HENRY CORNELIUS (1486-1535), German writer, soldier, physician and by common reputation a magician. Agrippa was for many years in the service of Maximilian I., the German king, who sent him in 1510 on a diplomatic mission to England, where he was the guest of Dean Colet. From 1511 to 1518 he was in Italy in the service of William VI. of Monferrato and of Charles III. of Savoy. His interest in the occult sciences had brought him into conflict with the church at Dôle in 1509 when he lectured on John Reuchlin's *De verbo mirifico*; again at Pavia in 1515 when he lectured at the university on the *Pimander* of Hermes Trismegistus; and again at Metz in 1518, where he was town orator, for his defence of a woman accused of witchcraft. He then practised medicine in Cologne, Geneva, Freiburg and Lyons for short periods until Margaret, duchess of Savoy and regent of the Netherlands, appointed him archivist and historiographer to the emperor. Margaret's death in 1530 weakened his position, but after suffering a short imprisonment for debt at Brussels he lived at Cologne and Bonn, under the protection of Hermann of Wied, archbishop of Cologne. He then went to France, where he was arrested by order of Francis I. for some disparaging words about the queen-mother; but he was soon released, and on Feb. 18 1535, died at Grenoble. He was thrice married and had a large family. Agrippa's work, *De occulta philosophia*, which brought him into antagonism with the Inquisition, was written about 1510, partly under the influence of the author's friend, John Trithemius, abbot of Würzburg, but its publication was delayed until 1531, when it appeared at Antwerp. It is a defence of magic, by means of which men may come to a knowledge of nature and of God, and contains Agrippa's idea of the universe with its three worlds or spheres. His other principal work, *De incertitudine et vanitate scientiarum et artium atque excellentia Verbi Dei declamatio*, was written about 1527 and published at Antwerp in 1531. In it Agrippa denounces the accretions which had grown up around the simple doctrines of Christianity, and wishes for a return to the primitive belief of the early Christian church. He also wrote *De nobilitate et praecellentia feminei sexus*, dedicated to Margaret of Burgundy, *De matrimonii sacramento* and other smaller works. An edition of his works was published at Leyden in 1550 and they have been republished several times.

See H. Morley, *Life of H. C. Agrippa* (London, 1856); A. Prost, *Les sciences et les arts occultes au XVI. siècle: Corneille Agrippa, sa vie et ses oeuvres* (Paris, 1881); A. Daguet, *Cornelius Agrippa* (Paris, 1856); J. Orsier, *H. C. Agrippa, sa Vie et son Oeuvre* (1911).

AGRIPPINA, the "elder," daughter of Marcus Vipsanius Agrippa (q.v.) by his third wife Julia, was the granddaughter of Augustus and the wife of Germanicus. She accompanied her husband to Germany, when the legions on the Rhine revolted after the death of Augustus (A.D. 14). Three years later she was in the East with Germanicus (q.v.), who died at Antioch in 19, poisoned, it was said, by order of Cn. Calpurnius Piso, governor of Syria. Eager to avenge his death, she returned to Rome and boldly accused Piso of the murder of Germanicus. To avoid public infamy Piso committed suicide. Tiberius and his favourite Sejanus feared that her ambition might lead her to attempt to secure the throne for her children, and she was banished to the island of Pandataria off the coast of Campania, where she died on Oct. 18, 33, starved to death by herself, or, according to some, by order of Tiberius. Two of her sons, Nero and Drusus, had already fallen victims to the machinations of Sejanus. Agrippina had a large family by Germanicus, several of whom died young, while only two are of importance—Agrippina the "younger" and Gaius Caesar, who succeeded Tiberius under the name of Caligula. There is a portrait of Agrippina in the Capitoline Museum at Rome and a bronze medal in the British Museum, representing the bringing back of her ashes to Rome by order of Caligula.

See Tac. *Ann.* i.-vi.; Suetonius *Tiberius*, 53; Dio Cassius lvii. 6, lviii. 22, lix. 3; Elizabeth Hamilton, *Memoirs of the Life of Agrippina* (1804); Stahr, *Römische Kaiserfrauen* (1880).

AGRIPPINA, the "younger" (A.D. 16-59), daughter of Germanicus and Agrippina the elder, sister of Caligula and mother of Nero, was born at Oppidum Ubiorum on the Rhine, afterwards named in her honour Colonia Agrippinae (mod. Cologne). By her first husband, Gnaeus Domitius Ahenobarbus, she was the mother of the emperor Nero; her second husband was Passienus Crispus, whom she was accused of poisoning, in 49. After the death of Messalina, she married the emperor/Claudius, her uncle, and induced him to adopt the future Nero as heir to the throne in place of his own son (Britannicus). In 54 she poisoned Claudius and secured the throne for her son. Being alarmed at the influence of the freedwoman Acte over Nero, she threatened to support the claims of the rightful heir Britannicus. Nero thereupon murdered the young prince and decided to get rid of his mother. Pretending a reconciliation, he invited her to Baiae, where an unsuccessful attempt was made to drown her on a vessel especially constructed to founder. Eventually he had her put to death at her country house. Agrippina wrote memoirs of her times, referred to by Tacitus (*Ann.* iv. 53).

See Tac. *Ann.* xii., xiii., xiv.; Dio Cassius lix.-lxi.; Suetonius, *Nero*, 34; Stahr, *Agrippina, die Mutter Neros* (1880); Raffay, *Die Memoiren der Kaiserin Agrippina* (1884); B. W. Henderson, *The Life and Principate of the Emperor Nero* (1903); J. MacCabe, *Empresses of Rome*, ch. v. (1911); also article **NERO**.

AGRONOMY, the theory and practice of land management and husbandry; in the United States more specifically used of the production of farm crops and plant culture, e.g., the agronomy department attached to the agricultural experiment stations.

AGROTERAS THUSIA, an annual festival held at Agrae, near Athens, in honour of Artemis Agrotera, in fulfilment of a vow made by the city, before the battle of Marathon, to offer in sacrifice a number of goats equal to that of the Persians slain in the conflict. The number being so great, it was decided to offer 500 goats yearly.

See Plutarch, *De Maliginitate Herodoti*, 26; Xenophon, *Anab.* iii., 2. 12; Aelian, *Var. Hist.* ii., 25; Schol. on Aristophanes, *Equites*, 660.

AGUADILLA, the largest and most important town in the north-western section of Porto Rico. The population by the 1920 census of the town itself was 8,035 (1930, 10,952), while the population of the municipal district in 1930 was 28,319.

Aguadilla is situated on the west coast of Porto Rico, on the Mona channel which connects the Atlantic ocean with the Caribbean sea. It is a seaport, but at present has little shipping. It is situated on the belt-line railroad which follows the coastal plains around the island and also has connection by well-built highways with the principal cities of the island. It has several industries and its business houses are well established. Its schools are superior, and an old church is of especial interest.

According to tradition, Columbus's fleet of discovery in 1493 refilled its water-casks at the fountain which still flows in the centre of the town. It is certain that Columbus's landing was near Aguadilla. A tract of land south of the town and within a short distance has been secured for a Columbus park, which will be improved and a creditable monument erected to the discoverer. There is no other place under the U.S. flag on which Columbus landed except Porto Rico. (H. M. T.)

AGUASCALIENTES, an inland State of Mexico, bounded north, east and west by the State of Zacatecas, and south by Jalisco. Pop. (1910) 120,511; (1921) 107,581. Area, 2,499sq. miles. The State occupies a part of the plateau of central Mexico about 6,000ft. above sea level, extending from two spurs of the Sierra Madre, called the Sierra Fria and Sierra de Laurel, eastward to the rolling fertile plains of its eastern and south-eastern districts. It is well watered by numerous small streams and one large river, the Aguascalientes or Rio Grande, and has a mild healthy climate with a light rainfall. The fertile valleys of the north and west are devoted to agriculture and the plains to stock-raising. Indian corn, flour, cattle, horses, mules and hides are exported to the neighbouring States. Mining industries are still undeveloped, but considerable progress has been made in manufactures, especially of textile fabrics. The State has good railway communications and a prosperous trade. The capital, Aguascalientes, named from the medicinal hot springs near it, is a flourishing commercial and manufacturing city. Pop. (1910) 45,198, (1921) 48,141. It has cotton factories, smelting works, railway shops, potteries, tanneries, distilleries and wagon and tobacco factories. It is a station on the Mexican Central railway, 364m. N.W. of the city of Mexico, and is connected by rail with Tampico on the Gulf of Mexico. The city is well built, has many fine churches and good public buildings, street cars and electric lights. Other towns of the State are Rincón de Romos, Asientos de Ibarra and Calvillo, each having less than 5,000 inhabitants.

AGUE, the common name given to a form or stage of malarial disease; the ague fit is the cold, shivering stage, and hence the word is also loosely used for any such paroxysm. (See **MALARIA**.) For "brow-ague" see **NEURALGIA**.

AGUESSEAU, HENRI FRANCOIS D' (1668-1751), chancellor of France, was born at Limoges Nov. 27 1668, the son of Henri d'Aguesseau, who held many important posts in the Government. He studied law under Jean Domat and was one of the first masters of forensic eloquence in France. He was procurator general from 1700 to 1717, and defended the rights of the Gallican Church against Rome in the controversy which led to the promulgation of the bull *Unigenitus*.

In 1717 he was made chancellor by the Regent Orleans, but was dismissed next year because of his steady opposition to the financial projects of John Law which had been adopted by the regent. He was recalled in 1720. He then assented to the truce which Dubois made with Rome because he feared the outbreak of civil war. Popular opinion unjustly ascribed his attitude to base compliance with Dubois; but he opposed other measures of Dubois and was dismissed when the favourite became chief minister. After five years of retirement spent in study, he was recalled by Cardinal Fleury, and again became chancellor. He attempted, in vain, the codification of French law, but he executed a body of reform which placed him in the same rank with L'Hôpital and Lamoignon.

His grandson, **HENRI CARDIN JEAN BAPTISTE, MARQUIS D'AGUESSEAU** (1746-1826), was advocate general in the parlement of Paris and deputy in the Estates-General. Under the Consulate he became president of the court of appeal and later minister at Copenhagen. He was elected to the French Academy in 1787.

CATHEDRAL AT AGUASCALIENTES
Aguascalientes, capital of the inland Mexican State of the same name, is an industrial centre for the agricultural plateau surrounding it

Of H. F. d'Aguesseau's works the most complete edition is that of Jean Marie Pardessus, published in 16 vol. (1818-20); his letters were edited separately by Rives (1823); a selection of his works, *Oeuvres choisies*, was issued, with a biographical notice, by E. Falconnet in 2 vol. (Paris, 1865). His works include a treatise on money; a life of his father, which is interesting from the account which it gives of his own education; and *Metaphysical Meditations*.

See Charles Butler, *Mem. of Life of H. F. d'Aguesseau*, etc. (1830); Boullée, *Histoire de la vie et des ouvrages du chancelier d'Aguesseau* (Paris, 1835); Fr. Monnier, *Le Chancelier d'Aguesseau* (Paris, 1860; 2nd ed., 1863).

AGUILAR, GRACE (1816-47), English writer, the daughter of a Jewish merchant in London, was born in June 1816. Her works consist chiefly of religious fiction, such as *The Vale of Cedars* (1850) and *Home Influence* (1847). She also wrote, in defence of her faith and its professors, *The Spirit of Judaism* (1842) and other works. She died at Frankfurt-on-Main on Sept. 16, 1847.

AGUILAR, or **AGUILAR DE LA FRONTERA**, a town of southern Spain, in the province of Cordova. Pop. (1920) 14,864. Aguilar "of the Frontier" was so named in the middle ages from its position on the border of the Moorish territories. Situated in the south of the fertile *Campaña de Córdoba*, its olives and white wine are celebrated; the wine is known as Amontillado, from the adjacent town of Montilla.

ÁGUILAS, seaport and railway terminus, south-east Spain, province of Murcia. Pop. (1920) 17,078. Águilas is built on the landward side of a small peninsula, between two bays and has a good harbour. It is the chief outlet for the Spanish trade in esparto grass, and exports also iron ore and other mineral products of the neighbourhood.

AGUINALDO, EMILIO (c. 1869-), Filipino insurrectionary leader, was born near Cavite, Luzon, of Chinese and Tagalog parentage. He was educated in his native town and in the University of St. Thomas, conducted by Dominican friars in Manila. At the outbreak of the insurrection in Aug. 1896, he was mayor of Cavite Viejo. During this uprising Aguinaldo took a prominent part, displaying marked capacity for leadership and assuming dictatorial powers. But in Jan. 1898 he left the Philippines for Hongkong, agreeing to remain permanently in exile on condition of a substantial financial reward from Spain. Immediately after the battle of Manila, May 1, 1898, he returned to the Philippines with the express purpose, it is said, of assisting the United States in the war with Spain. Obtaining the consent of the U.S. authorities, he established a native government, of which he became the head, and organized an army. On Feb. 4, 1899, he began hostilities against the United States by making an unsuccessful attack on Manila. During 1899 there were several severe engagements, but in the end the native troops became so hard pressed that Aguinaldo, after repeatedly changing his capital, was forced to take refuge in the mountains. Here the struggle was protracted until March 23, 1901, when he was captured by Gen. Frederick Funston at Palawan, Luzon. On April 19, 1901, Aguinaldo took the oath of allegiance to the United States and retired to peaceful private life.

AGUIRRE, LOPE DE (1508-1561), Spanish adventurer. In 1559 he joined Pedro de Ursua's expedition to the Upper Amazon, in search of El Dorado, and took part in the murder of Ursua and his lieutenant in 1561, after which Guzman was elected captain by the crew, with Aguirre as his master of the camp. The murderers declared themselves rebels, and sailed down the Amazon, plundering and putting to the sword whole villages of Indians. Aguirre established a reign of terror on board ship, which culminated in the murder of Guzman, and his own self-appointment to the position of captain. In July of 1561 the party reached Margarita Island, where they murdered the governor, robbed the royal treasury and proceeded to make incursions into the mainland of Venezuela. About this time Aguirre wrote and despatched an amazing letter to the king of Spain, accusing him of ingratitude toward himself, Aguirre, and his followers, and giving a full account of his own villainous exploits on the voyage.

Soon after, his men began to desert him and just when an attack was expected from Spanish troops, he was shot by his own fellow-rebels, in Oct. 1561.

See R. Southey, *Expedition of Orsua, and the Crimes of Aguirre* (1821); and P. Simon, *The Expedition of Pedro de Ursua and Lope de Aguirre in search of El Dorado and Omagua* (1861).

AGUJARI, LUCREZIA (1743-1783), an Italian operatic singer, possessed of one of the most extraordinary voices, in respect of its almost incredible compass, ever known. Mozart, who heard her at Parma in 1770, noted down some of the passages which she sang, showing her range to have extended from middle C to C in altissimo, or more than an octave above the B flat which is about the limit of the average soprano. At the same time she was a brilliant executant. Known (and advertised) as *La Bastardella*, on account of the circumstances of her birth, as the natural daughter of a man of rank, she paid many visits to London where she received as much as £100 a night.

AHA, of Shabha, an 8th-century Talmudist. He was author of *Quaestiones* (*Sheiltoth*), a collection of homilies (at once learned and popular) on Jewish law and ethics. This is recorded as the first work written by a Jewish scholar after the completion of the Talmud.

AHAB, son of Omri, king of Israel from c. 875 to c. 852 B.C. (I Kings xvi. 29-xxii. 40). The more important aspects of his reign, which in some respects marks the high water mark of the success of the northern kingdom, may be summarized as follows: (1) *Foreign relations*.—In the reigns of Omri and Ahab the northern kingdom for the first time took an important part in international politics. Omri left to his son an empire which comprised not only territory to the east of Jordan, in Gilead and probably Bashan, but also the land of Moab, whose king was tributary, while Judah (and probably Edom also) if not actually subject to Omri, was certainly a subordinate ally. Ahab's marriage with Jezebel, daughter of Ethbaal of Sidon, revived an alliance which had been in abeyance since the time of Solomon. But throughout the reign of Ahab a fierce border war was waged with Damascus, in which Israel, in spite of occasional victory, proved the weaker, while Mesha, king of Moab, successfully revolted and occupied the southern portions of the territory of Gad. Yet the forces of Israel retained strength enough to contribute the second largest contingent of soldiers (the largest force of chariots) to the combined armies which, under the leadership of Benhadad of Damascus, checked the westward movement of Shalmaneser III. of Assyria at Karkar in 853 B.C. After the Assyrian repulse, however, the alliance broke up, and Ahab met his death fighting the Syrians in a vain attempt to recover Ramoth Gilead. (2) *Domestic affairs*.—Contact with a wider world, and especially the alliance with Phoenicia, had far-reaching results for the kingdom of Israel itself. Jezebel attempted to introduce into religion and government elements which were common enough elsewhere in the ancient world but strange in Israel. She endeavoured to set up the worship of the Tyrian Baal in Samaria, and to maintain the familiar oriental principle of the absolute despotic power and authority of the sovereign. This roused the bitter hostility of that conservative party which clung to the sole worship of the national God, Yahweh, and at the same time held to those democratic conceptions of society which the Hebrews had brought with them from the wilderness and had consistently maintained through their history. The spirit of this party found expression in the prophet Elijah (q.v.), who protested alike against the establishment of the Baal priests and the judicial murder of Naboth. He and those who came after him seem to have been successful in eliminating the foreign worship, though in the end their purpose was only achieved by a bloody revolution; but they were powerless to stem the tide of social and moral deterioration. (See Amos.) It is to the reign of Ahab that we may trace the beginning of that sapping of the national life which led to the condemnations of the 8th century prophets and to the downfall of Samaria. (T. H. R.)

AHAGGAR, general name for a large plateau region of the north centre of the Sahara, culminating about 900m. due S. of Algiers and 1,200m. due N. of the mouth of the Niger. The

highest peaks do not greatly exceed 8,000ft. above sea-level. (See also SAHARA.)

AHASUERUS, a royal Persian name occurring in Ezra iv. 6, Dan. ix. 1, and throughout the book of Esther, but its occurrence in Tobit xiv. 15, in some Greek mss., is due to a copyist's blunder. It is the Latinized form of the Hebrew *Ahāšwērōš* (LXX. Ἀσσοῦρος). In Ezra iv. 6 Ahasuerus is mentioned as a king of Persia, to whom the enemies of the Jews sent representations opposing the rebuilding of the temple at Jerusalem. He here occupies a place in a chronological series of those Persian rulers who were directly concerned with events of Jewish history. (See EZRA AND NEHEMIAH.) Immediately preceding Artaxerxes I. Longimanus, he is evidently to be identified with Xerxes. This conclusion is supported by the resemblance of the Hebrew form of the name to the Babylonian *Ahšiyarš(u)*, the Egyptian-Aramaic transliterations, etc. The old Persian form, found in inscriptions, is *Khšayāršā*.

In the book of Esther the king, at whose court the scene is laid, bears the same Hebrew name, rendered *Assuerus* in the Latin version and *Ahasuerus* in the English Bible (but in LXX. "Artaxerxes" throughout). Most modern scholars are agreed that here also Xerxes is the king intended. (See ESTHER.)

In Dan. ix. 1 "Ahasuerus" (*Ahāšwērōš*) is the father of "Darius the Mede," who is said to have become king over Babylonia upon the death of Belshazzar. (See also v. 30, vi. 1, 29.) The name seems impossible here, however, and is probably due to some accident in the literary transmission (Josephus, *Ant.* x. 11, 4, has "Astyages"). It was perhaps originally a Hebrew form of *Huwahšātara* (Cyaxares). No other name resembling Ahasuerus, nor any name like Darius, is to be found in the list of Median kings. We know, moreover, from the Cyrus cylinder, as well as from the Greek historians, that the immediate successor of Nabonidus and Belshazzar as ruler of Babylonia was Cyrus (he is represented in Dan. x. 1, xi. 1, as successor of this Darius). Comparison with the list of Persian kings in the book of Ezra (see above) seems to show that in the Jewish tradition Darius I. Hystaspis was placed before Cyrus as "Darius the Mede."

See articles "Ahasuerus" in the *Encyclopaedia Biblica*, Hastings' *Dictionary*, the *Jewish Encyclopaedia*; Driver, *Introd. to the Lit. of the Old Test.*; Torrey, *Ezra Studies*, pp. 38 seq., 135 seq., 141. (C. C. T.)

AHAZ, king of Judah. After the death of Menahem, Pekah, king of Israel, and Rezin (rather Rasun), king of Syria, allied against Assyria and invaded Judah. At the same time the Edomites recovered Elath on the Gulf of Akabah and Judah was isolated. Notwithstanding the counsel of Isaiah, Ahaz called in the aid of Tiglath-pileser I., who, after attacking the Philistines, destroyed the power of Syria, and exacted heavy tribute from Judah. It was as a vassal that Ahaz presented himself to the Assyrian king at Damascus, and brought back religious innovations, on the nature of which see W. R. Smith, *Relig. of Semites*, pp. 485 sqq. and commentaries on II. Kings xvi. 17.

AHAZIAH, the name of two kings in the Bible. (1) Ahaziah, 8th king of Israel, was the son and successor of Ahab, and reigned for less than two years. On his accession the Moabites refused any longer to pay tribute. Ahaziah lost his life through a fall from the lattice of an upper room in his palace (2 Kings i. 2-17). (2) Ahaziah, 6th king of Judah, son of Jehoram and Ahab's daughter Athaliah, reigned one year. He, together with Joram, king of Israel, was slain by Jehu, son of Nimshi. He is variously called Jehoahaz and Azariah (2 Kings viii. 25-ix. 28).

AHENOBARBUS [Lat. "brazen-bearded"], the name of a very extensive plebeian Roman family of the *gens Domitia*. The name was derived from the red beard and hair by which many of the family were distinguished. Amongst its members the following may be mentioned:—

GNAEUS DOMITIUS AHENOBARBUS, tribune of the people 104 B.C., brought forward a law (*lex Domitia de Sacerdotiis*) by which the priests of the superior colleges were to be elected by the people in the *comitia tributa* instead of by co-optation; the law was repealed by Sulla, revived by Julius Caesar and (perhaps) again repealed by Marcus Antonius, the triumvir (Cicero, *De*

Lege Agraria, ii. 7; Suetonius, *Nero*, 2). Ahenobarbus was elected pontifex maximus in 103, consul in 96 and censor in 92 with Lucius Licinius Crassus the orator, with whom he was frequently at variance. They took joint action, however, in suppressing the recently established Latin rhetorical schools, which they regarded as injurious to public morals (Aulus Gellius xv. 11).

LUCIUS DOMITIUS AHENOBARBUS, son of the above, and husband of Porcia the sister of Cato Uticensis. Being a convinced aristocrat he opposed Pompey and Caesar while they were united, and when their friendship cooled, attached himself to Pompey. He was consul in 54 B.C., and in 49 B.C. he was appointed by the senate to succeed Caesar as governor of Gaul. After the outbreak of the civil war he commanded the Pompeian troops at Corfinium, but was obliged to surrender. Although treated with great generosity by Caesar, he stirred up Massilia (Marseille) to an unsuccessful resistance against him. After its surrender, he joined Pompey in Greece and was slain in the flight after the battle of Pharsalus (Caesar, *Bellum Civile*, i., ii., iii.; Dio Cassius xxxix., xli.; Appian, B.C. ii. 82).

GNAEUS DOMITIUS AHENOBARBUS, son of the above, accompanied by his father at Corfinium and Pharsalus, and, having been pardoned by Caesar, returned to Rome in 46 B.C. After Caesar's assassination he attached himself to Brutus and Cassius, and in 43 B.C. was condemned by the *lex Pedia* as having been implicated in the plot. He obtained considerable naval successes in the Ionian Sea against the triumvirate, both before and after Philippi, but in 40 B.C. became reconciled to Antony, who made him governor of Bithynia. He took part in Antony's Parthian campaigns, and was consul in 32 B.C. When war broke out between Antony and Octavian, he at first supported Antony, but, disgusted with his intrigue with Cleopatra, went over to Octavian shortly before the battle of Actium (31 B.C.). He died soon afterwards (Dio Cassius xlviii.-l.; Appian, *Bell. Civ.*, iv., v.). His son was married to Antonia, daughter of Antony, and became the grandfather of the emperor Nero.

See Drumann, *Geschichte Rom.*, 2nd ed. by Groebe, vol. iii. pp. 14 ff.

AHITHOPHEL, one of David's most trusted advisers, whose counsel was "as though one inquired of the word of God." He took a leading part in Absalom's revolt, and his defection was a severe blow to the king, who prayed that God would bring his counsel to "foolishness." At Ahithophel's advice Absalom first took the precaution of asserting his claim to the throne by seizing his father's concubines. The immediate pursuit of David was then suggested but Hushai recommended waiting till the levies of all Israel could be called up. This advice was adopted, and David had time to escape across the Jordan. Finding that his policy was neglected, and foreseeing the disaster which actually occurred, Ahithophel went home and hanged himself. (2 Sam. xv. 31-37; xvi. 20-xvii. 14, 23.)

AHLEN, a town in the south-east of the district of Münster, in the Prussian province of Westphalia. Pop. (1925) 22,244. It produces metal-work, enamelling, die-stamping, galvanizing, etc.

AHMADABAD, a city and district of British India in the northern division of Bombay. The city was once the handsomest and most flourishing in western India, and it still ranks next to Agra and Delhi for the beauty and extent of its architectural remains. It was founded by Ahmad Shah in A.D. 1411 on a site used for earlier Hindu towns, and embellished with fine buildings of marble brought from a distance. The Portuguese Barbosa described it as "very rich and well embellished, with good streets and squares supplied with houses of stone and cement." In Sir Thomas Roe's time, A.D. 1615, "it was a goodly city as large as London." From 1411 to 1511 it grew in size and wealth; from 1512 to 1572 it declined with the decay of the dynasty of Gujarat; from 1572 to 1709 it renewed its greatness under the Moghul emperors; from 1709 to 1809 it dwindled with their decline; and from 1818 onwards it has again increased under British rule.

In consequence of these changes of dynasty, Ahmadabad became the meeting-place of Hindu, Mohammedan and Jain architecture. Ahmad Shah pulled down Hindu temples in order to build his mosques with the material. The Jama Masjid itself, with its 300 pillars fantastically carved, is a Hindu temple con-

verted into a mosque (see INDIAN ARCHITECTURE, Plate III., fig. 15). Many of the houses are beautifully carved and there are numerous fine mosques, tombs, etc. One of the finest is the modern Jain temple of Hathi Singh outside the Delhi gate, which was built only in 1848. Two of the windows in Sidi Said's mosque of filigree marble work are marvels of delicacy and grace, and finer than anything of the kind to be found in Agra or Delhi.

The modern city of Ahmadabad is situated on the left bank of the river Sabarmati; Sabarmati, on the opposite bank of the river, is practically part of Ahmadabad. Its population, which has steadily increased, was (in 1921) 274,007. It has a station on the Bombay and Baroda railway, 309m. from Bombay, whence

FROM "ARCHITECTURE OF AHMEDABAD," BY COURTESY OF JOHN MURRAY

THE TEMPLE OF HATHI SINGH AT AHMEDABAD, BUILT IN 1848 AS THE LOCAL SHRINE OF JAINISM

branch lines diverge to Delhi, Khed, Brahma and Dolka, and is the largest centre for trade and manufacture in the presidency after Bombay. Its native bankers, shopkeepers and workers are all strongly organized in guilds. It has numerous cotton mills, about one-third of the population being dependent on the cotton industry, and factories for ginning and pressing cotton. Other industries include oil, flour and silk mills, manufactures of soap, matches, glass, tobacco and hosiery, carpet works and tanneries. Ahmadabad is famous for its handicrafts, including brocades and tinsel lace, copper and brass working, jewellery and wood-carving. Filtered water is obtained from wells in the river bed and the main streets are lighted by electricity. The military cantonment, 3m. N. of the native town, is the headquarters of the northern division of the Bombay command, with an arsenal.

The district of Ahmadabad lies at the head of the Gulf of Cambay, between Baroda and Kathiawar. Area 3,824 square miles. The river Sabarmati and its tributaries, flowing from north-east to south-west into the Gulf of Cambay, are the principal streams that water the district. The north-eastern portion is dotted with low hills, which gradually sink into a vast plain, subject to inundation on its western extremity. With the exception of this latter portion, the soil is very fertile, and some parts are wooded. The population in 1921 was 890,911. The principal crops are millets, cotton, wheat and pulse. The district is traversed by the Bombay and Baroda railway, and has two seaports, Dholera and Gogo, the former of which has given its name to a mark of raw cotton in the Liverpool market.

AHMAD IBN HANBAL (780-855), the founder, involuntarily and after his death, of the Hanbalite school of canon law, was born at Baghdad in A.H. 164 (A.D. 780) of parents from Merv, but of Arab stock. He studied the Koran and its traditions (*hadith, sunna*) there and on a student journey through Mesopotamia, Arabia and Syria. After his return to Baghdad he studied under ash-Shāfi'i between A.H. 195 and 198, and became, for his life, a devoted Shāfi'ite. But his position in both theology and law was more narrowly traditional than that of ash-Shāfi'i; he rejected all reasoning, whether orthodox or heretical in its conclusions, and stood for acceptance on tradition (*naql*) only from the Fathers. In consequence, when al-Ma'mūn and, after him, al-Mu'tasim and al-Wāthiq tried to force upon the people the rationalistic Mu'tazilite doctrine that the Koran was created, ibn Hanbal, the most prominent and popular theologian who stood for the old view, was imprisoned and scourged. In A.H. 234, under al-Motawakkil, the Koran was finally decreed un-

created, and ibn Hanbal, who had come through this trial better than any of the other theologians, enjoyed an immense popularity with the mass of the people as a saint, confessor and ascetic. He died at Baghdad in A.H. 241 (A.D. 855) and was buried there.

BIBLIOGRAPHY.—On his great work, the *Musnad*, a collection of some 30,000 selected traditions, see Goldziher in *ZDMG*, l. 465 ff. For his life and works generally, see W. M. AHMADIYYAH: see ISLAM.

AHMADNAGAR, a city and district of British India in the central division of Bombay on the left bank of the river Sina. Pop. (1921) 49,878. The town was founded in 1494 on the site of a more ancient city, Bhingar, by Ahmad Nizam Shah, who established a new monarchy, which lasted till its overthrow by Shah Jahan in 1636. In 1759 the Peshwa obtained possession of the place by bribery, and in 1797 it was ceded to the Mahratta chief, Daulat Rao Sindhia. During the war with the Mahrattas in 1803 Ahmadnagar was invested by Gen. Wellesley and captured. Restored to the Mahrattas, it again became a British possession in 1817, under the Treaty of Poona. There is a large trade in cotton and silk goods, while turbans and copper and brass pots are made. There are also factories for ginning and pressing cotton, indigo works and a tannery. Ahmadnagar is a station on the loop line of the Great Indian Peninsula railway, 218 m. from Bombay, a military station of the Poona district and an important mission station.

The district of Ahmadnagar is a comparatively barren tract with a small rainfall. The area is 6,610 square miles. The population in 1921 was 731,552, showing a considerable decrease in the decade. On the north the district is watered by the Godavari and its tributaries, the Prawara and the Mula; on the north-east by the Dor, another tributary of the Godavari; on the east by the Sephani, which flows through the valley below the Balaghat range; and in the extreme south by the Bhima and its tributary the Gor. The Sina river, another tributary of the Bhima, flows through the Nagar and Karjat talukas. The principal crops are cotton, millet, pulse and wheat and dyes are produced.

AHMAD SHAH (1724–73), founder of the Durani dynasty in Afghanistan, was the son of Sammaun-Khan, hereditary chief of the Abdali tribe. While still a boy, Ahmad fell into the hands of the hostile tribe of Ghilzais, by whom he was kept prisoner at Kandahar. In March 1738 he was rescued by Nadir Shah, who soon afterwards gave him the command of a body of cavalry composed chiefly of Abdalis. On the assassination of Nadir in 1747, Ahmad, having failed in an attempt to seize the Persian treasures, retreated to Afghanistan, where he persuaded the tribes to assert their independence and accept him as their sovereign. He was crowned at Kandahar in Oct. 1747, and about the same time he changed the name of his tribe to Durani. He first crossed the Indus in 1748, when he took Lahore; and in 1751, after a feeble resistance on the part of the Mohammedan viceroy, he became master of the entire Punjab. In 1750 he took Nishapur, and in 1752 subdued Kashmir. His great expedition to Delhi was undertaken in 1756 in order to avenge himself on the Great Mogul for the recapture of Lahore. Ahmad entered Delhi with his army in triumph, and for more than a month the city was given over to pillage. The shah himself added to his wives a princess of the imperial family, and bestowed another upon his son Timur Shah, whom he made governor of the Punjab and Sirhind. As his viceroy in Delhi he left a Rohilla chief in whom he had all confidence, but scarcely had he crossed the Indus when the Mohammedan wazir drove the Afghan chief from the city, killed the Great Mogul and set another prince of the family, a tool of his own, upon the throne. The Mahratta chiefs availed themselves of these circumstances to endeavour to possess themselves of the whole country, and Ahmad was compelled more than once to cross the Indus in order to protect his territory from them and the Sikhs, who were constantly attacking his garrisons. In 1758 the Mahrattas obtained possession of the Punjab, but on Jan. 6, 1761, they were totally routed by

Ahmad in the great battle of Panipat. In a later expedition he inflicted a severe defeat upon the Sikhs, but had to hasten westwards immediately afterwards in order to quell an insurrection in Afghanistan. Meanwhile the Sikhs again rose, and Ahmad was forced to abandon all hope of retaining the command of the Punjab. He died in 1773, leaving to his son Timur the kingdom he had founded.

AHMED I. (1589–1617), sultan of Turkey, was the son of Mohammed III., whom he succeeded in 1603, being the first Ottoman sultan who reached the throne before attaining his majority. He was of kindly and humane disposition, as he showed by refusing to put to death his brother Mustafa, who eventually succeeded him. In the earlier part of his reign he gave proofs of decision and vigour, which were belied by his subsequent conduct. The wars which attended his accession both in Hungary and in Persia terminated unfavourably for Turkey, and her prestige received its first check in the peace of Sitvatörök, signed in 1606, whereby the annual tribute paid by Austria was abolished. Ahmed gave himself up to pleasure during the remainder of his reign—which ended in 1617—and demoralization and corruption had become as general throughout the public service as indiscipline in the ranks of the army. The use of tobacco is said to have been introduced into Turkey during Ahmed I.'s reign.

AHMED II. (1643–95), sultan of Turkey, son of Sultan Ibrahim, succeeded his brother Suleiman II. in 1691. His chief merit was to confirm Mustafa Kuprili as grand vizier. But a few weeks after his accession Turkey sustained a crushing defeat at Slankamen (1691) from the Austrians under Prince Louis of Baden and was driven from Hungary; during the four years of his reign disaster followed on disaster, and on Feb. 6, 1695, Ahmed died, worn out by disease and sorrow.

AHMED III. (1673–1736), sultan of Turkey, son of Mohammed IV., succeeded to the throne in 1703 on the abdication of his brother Mustafa II. He cultivated good relations with England, and he afforded a refuge in Turkey to Charles XII. of Sweden, after his defeat at Poltava (1709). Forced into war with Russia, he came nearer than any Turkish sovereign before or since to breaking the power of his northern rival, whom his Grand Vizier, Baltaji Mohammed Pasha succeeded in completely surrounding near the Pruth (1711). In the treaty which Russia was compelled to sign Turkey obtained the restitution of Azov, the destruction of the forts built by Russia, and the undertaking that the tsar should abstain from future interference in the affairs of the Poles or the Cossacks. Discontent at the leniency of these terms was so strong at Constantinople that it nearly brought on a renewal of the war. In 1715 the Morea was taken from the Venetians. This led to hostilities with Austria, in which Turkey was unsuccessful, and Belgrade fell into the hands of Austria (1717). Through the mediation of England and Holland the peace of Passarowitz was concluded (1718), by which Turkey retained her conquests from the Venetians, but lost Hungary. A war with Persia terminated in disaster, leading to a revolt of the janissaries, who deposed Ahmed in Sept. 1730. He died in captivity.

AHMED KUPRILI: see KUPRILI.

AHMED VEFIK, PASHA (1810–1891), Turkish statesman and man of letters, was born in Stambul and educated in Paris. He was appointed to a post in the *bureau de traduction* of the ministry for foreign affairs, and devoted his leisure to the translation of Molière's plays into Turkish and to the compilation of educational books (dictionaries, historical and geographical manuals, etc.) for use in Turkish schools. In 1847 he brought out the first edition of the *Salmameh*, the official annual of the Ottoman empire. Two years later he was appointed imperial commissioner in the Danubian principalities, and in 1851 ambassador to Persia. After his return he was appointed a member of the Grand Council of Justice, and was entrusted with the revision of the penal code and the code of procedure.

In 1860 he was sent as ambassador to Paris, to avert the intervention of France in the affairs of Syria. Ahmed Vefik held various important posts in the Turkish Government during the next two decades, and was twice minister of public instruction, but the position in which he rendered his most distinguished

service was as vali of Brusa (1879-82). The drainage of the pestilent marshes, the water-supply from the mountains, the numerous roads, the suppression of brigandage, the multiplication of schools, the vast development of the silk industry through the substitution of mulberry plantations for rice-fields, the opening out of the mineral springs of Chitli, the introduction of rose trees and the production of attar of roses—all these were Ahmed Vefik's work. A few days after his return he was again appointed prime minister (Dec. 1, 1882), but he made conditions which were unacceptable to the sultan, and Said Pasha was appointed in his place. For the rest of his life Ahmed Vefik, by the sultan's orders, was practically a prisoner in his own house.

Ahmed Vefik was a great linguist. He spoke and wrote French perfectly, and thoroughly understood English, German, Italian, Greek, Arabic and Persian. From all these languages he translated many books into Turkish, but wrote no original work. His splendid library of 15,000 volumes contained priceless manuscripts in many languages. In his lifetime he appreciably aided the progress of education; but, as he had no following, the effects of his labour and influence in a great measure faded away after his death.

AHOM, the branch of the Tai race settled in and giving its name to Assam (*q.v.*). This people came into Assam in the 13th century under a leader named Sukupha and gradually extended their rule westward down the Brahmaputra valley, which they dominated till its invasion by the Burmese early in the 19th century. They instituted and retained in Assam a form of government in which taxes were paid by personal service and the population was organized in *paiks* of three householders, one of whom had always to be on duty. Religion was animistic until Hinduized; society was organized in clans (*khel*), originally exogamous, but tending to become under Hinduism endogamous occupational groups. There was a written language in script derived ultimately from Devanagari, but now, like the spoken tongue, extinct, though palm-leaf books written in it are still extant. (See also SHAN.)

See Hastings' *Encyclopaedia of Religion and Ethics* (*s.v.*) "Ahom"; E. A. Gait, *History of Assam* (1926).

AHRENS, FRANZ HEINRICH LUDOLF (1809-81), German philologist, was born at Helmstedt, June 6, 1809, and died Sept. 25, 1881. His most important work is *De Graecae Linguae Dialectis* (1839-43, new ed. by Meister, 1882-89), which, although unfortunately incomplete, dealing only with Aeolic and Doric, and in some respects superseded by modern research, remains a standard treatise. A volume of his minor works (ed. Haebler, 1891) contains a complete list of his writings.

AHRIMAN, the name of the principle of evil in the dualistic doctrine of Zoroaster (Gr. *Ἀριμάνιος* in Aristotle, or *Ἀριμάνης* in Agathias; in the *Avesta*, *Añgrô Mainyush*)—"the Destructive Spirit"). In the *Avesta* he is called the twin-brother of the Holy Spirits, and contrasted either with the Holy Spirit of Ormazd or with Ormazd himself. He is the all-destroying Satan, the source of all evil in the world. Eventually, in the great world catastrophe, he will be defeated by Ormazd and disappear. (See ZOROASTER.)

AHRWEILER, a town in Rhenish Prussia, Germany, on the river Ahr. Pop. (1925) 6,750. The town is surrounded by mediaeval walls and gates. The Gothic church dates from 1245. There is trade in the red wine of the district.

AHT, a confederacy of 22 tribes of North American Indians of the Wakashan stock. They are settled on the west coast of Vancouver, British Columbia. The chief tribes included are the Nitinaht, Tlaasht or Makah, Tlaokiwaht or Clahoquaht, Ahan-sht and Ehatishaht. In the year 1928 the confederacy numbered some 3,500.

AHTENA ("ice people"), the name of an Athapascan tribe of North American Indians, in the basin of Copper river, Alaska.

See *Handbook of American Indians*, ed. F. W. Hodge (Washington, 1907).

AHURA MAZDA, the Good Spirit in the dual system of Zoroaster, opposed to Ahriman, Angra Mainyu or Druj, the Spiritual Enemy. The name is sometimes translated as the "Wise Lord" and it is the origin of the modern Persian *Ormazd* or *Ormuzd*.

AHWAZ, a town of south-west Persia, in the province of Khuzistan, on the left bank of the River Karun, 85m. by road and 105m. by river from Mohammerah (*q.v.*), 31° 20' N., 48° 48' E. It has been identified with the Aginis of Nearchus, and occupies the site of what was once an extensive and important city, of which, however, very few vestiges remain, the present town having been built in the last 50 years from the ruins of the old. Close by are to be seen the ruins of a stone dam of great strength, constructed across the Karun for the purposes of irrigation. Dependent on it was a system of great canals on both banks which served in the 12th and 13th centuries, if not before, to irrigate an area which was estimated by Major W. R. Morton, R. E., in 1907, at approximately half a million acres. Arab historians of the 12th and 13th centuries describe Ahwaz as the centre of a great sugar, rice and silk growing area, exporting its products all over Persia and as far west as Syria. Since the opening of the Karun to foreign commerce in Oct. 1888 another settlement, called Bandar Násiri, in compliment to the Shah Násir ed Din (d. 1896), has arisen, 1m. below Ahwaz, at the point below the rapids where steamers come to anchor. Here are situated the Government post and telegraph offices, the British consulate and the Soviet consular agency. Bandar Násiri is an official port of entry under the Anglo-Persian Commercial Convention of 1903, and a custom-house is established there. The climate is dry and healthy and the town, which was well laid out between 1903 and 1925 by the Arab governor of the province, Shaikh Khazál, has a mixed Persian and Arab population of some 15,000 souls. The Anglo-Persian Oil Company's European staff at Ahwaz, where some 70,000 tons of cargo are transhipped annually and where their work-shops and stores are situated, number about 70, together with some 2,000 Persians, for most of whom special quarters have been built north of the old town. Motor routes run from Ahwaz along the right bank of the Karun and Diz to Dizful (85m.), to Shushtar (64m.), crossing the Karun at Band-i-Qir (28m.), and to Ram Hormuz (60m.) and Behbahan (126m.) (*q.v.*) and Masjid Suleiman (70 miles). An important caravan route also runs from Ahwaz to Isfahan (271m.) via Malamir.

AI (*ah'è*), a three-toed sloth (*Bradypus tridactylus*), a tree-dwelling mammal native to dense forests in tropical America, so called because of its plaintive cry which somewhat resembles the sound indicated by its name. For descriptive details and illustration see EDENTATA: *Pilosa*; SLOTH.

AI, in Hebrew always with the definite article, *Haai*, "the heap of ruins." Other forms of the name are *Ayya* (Neh. ii. 31), *Ayyath* (Isa. x. 28). Some mss. read, probably correctly, *Ayya* for Gaza in I Chron. vii. 28. It was a royal city of the Canaanites and is best known for its complete destruction by Joshua (viii. 28), from which time, indeed, the name may date. Abraham pitched his tent between Ai and Bethel (Gen. xii. 8, xiii. 3). It lay somewhere east of Bethel (Beitin) near Beth-Aven with valleys to the north and west (Josh. viii. 11, 12). Identifications have fluctuated. Et-Tell (*Tell el-Hajar*), Khirbet el-Qudeira, Khirbet el-Haya and Khirbet Hayyan, all of which are mounds or ruined sites in the neighbourhood, have had their advocates. The weight of authority now favours Khirbet Hayyan with visible evidence of extensive habitation in rock-hewn reservoirs and débris of stone buildings. This site is rather more than 2m. south-east of Beitin on the road leading to the Jordan valley.

See *Pal. Expl. Fund. Quart. Statement* (1869), p. 123; (1874), p. 62-4; (1878), pp. 10, 132, 195; (1881), p. 254; E. Robinson, *Bib. Researches*, i. 143, ii. 312 ff.; Sellin, *Mitt. des Deutsch. Palästina Vereins* (1900), p. 1 ff.; W. F. Albright, *Annual Amer. Schools of Orient. Research* (1924), appendix v. (E. Ro.)

AICARD, JEAN FRANÇOIS VICTOR (1848-1921), French poet and dramatist, was born at Toulon. He went to Paris to study law, and his first visit was to Victor Hugo, who returned the young man's admiration in kind, and is reported to have said in the Académie Française, "Je promets ce poète à la France." Aicard won the Vitet prize, and soon became known in literary circles in Paris for the charm and luminous simplicity of his verse. His poetry includes: *Les Rébellions et les apaisements* (1871); *Poèmes de Provence* (1874), and *La Chanson de l'enfant* (1876), both of which were crowned by the Academy; *Miette et Noré*

(1880), a Provençal idyll; *Le Livre d'heures de l'amour* (1887); *Jésus* (1896), etc. Of his plays the most successful was *Le Père Lebonnard* (1890), which was originally produced at the Théâtre Libre. Among his other works are the novels, *Le Roi de Camargue* (1890), *L'Âme d'un enfant* (1898) and *Tatas* (1901), *Benjamine* (1906) and *La Vénus de Milo* (1874), an account of the discovery of the statue from unpublished documents.

AICHINGER, GREGOR (c. 1565–1628), a distinguished composer. He was organist to the Fugger family at Augsburg in 1584. Proske, in the preface to vol. ii. of his *Musica Divina*, calls him a priest of Regensburg, and is inclined to give him the palm for the devout and ingenuous mastery of his style.

AIDAN (or AEDAN), a monk of Iona, and first bishop of Lindisfarne (A.D. 635–651). In 635 Oswald, who had succeeded to the kingdom of Bernicia in the previous year, re-united the whole of Northumbria under himself. Northumbria had been converted to Christianity by Paulinus (625–633), but had relapsed under the heathen successors of Edwin, and in 635 Oswald, who was an earnest Christian, sent for a new bishop. Paulinus had been a member of the Roman Church, but his successor was summoned from the headquarters of the Celtic church, the monastery of Iona, which Oswald had visited during his exile. The first monk sent was unsuccessful; when he reported at Iona that he could do nothing with the uncouth Northumbrians, Aidan suggested that "he had not first given them the milk of mild doctrine . . . until they were able to understand the more perfect mysteries . . . of God." Thereupon it was decided to send Aidan as bishop to Northumbria.

True to the traditions of the Celtic church, he fixed his abode on the island of Lindisfarne. Under his influence, and that of the Irish monks who joined him, churches were built, and monasteries established, and a school founded where 12 boys were trained as preachers.

Christianity spread apace through Northumbria, partly because Aidan was building on the foundations laid by Paulinus, and partly because of the active support given by Oswald. There was a close friendship between king and bishop, and Bede tells us that when Aidan was preaching, Oswald, who understood Scottish, would often act as his interpreter. But the main cause of Aidan's success was his own character; Bede, though disapproving of his observance of the Celtic Easter, gives him the highest praise for his learning, simplicity of life, and open-handed generosity. "What chiefly commended his teaching to all men was that it agreed with the life he and his followers led."

The defeat and death of Oswald at Maserfield (Aug. 5, 642) did not destroy the Northumbrian Church; though the kingdom was divided, Aidan retained his see, and legend tells that his prayers saved Bamburgh from destruction by Mercian invaders. He died at Bamburgh, Aug. 31, 651, eleven days after the murder of his friend, King Oswin of Deira.

Aidan by his energy and saintly character had established in Northumbria Christianity in its Celtic form. But the phase was not lasting; in 664, at the Synod of Whitby, Oswy adopted the Roman Easter, and, abandoning the Celtic church with its monastic ideal, brought Northumbria again into touch with the Christianity of Southern England and the Continent.

See Bede, *Hist. Eccl.* iii. 3, 5, 14–17, 25—Plummer's edition, with excursus on the Paschal Controversy; Oman, *England before the Conquest* (1921), ch. xiv.; W. Bright, *Chapters of Early English Church History* (1897) chaps iv., v. See article EASTER.

AIDAN (d. 606), king of the Scottish kingdom of Dalriada, was the son of Gabran, king of Dalriada, and became king after the death of his kinsman, King Conall, when he was crowned at Iona by St. Columba. He refused to allow his kingdom to remain in dependence on the Irish Dalriada, but coming into collision with his southern neighbours he led a large force against Aethelfrith, king of the Northumbrians, and was defeated at a place called Daegsanstane, probably in Liddesdale.

See Bede, *Historiae Ecclesiasticae gentis Anglorum*, ed. by C. Plummer (1896); Adamnan, *Vita S. Columbae*, ed. by J. T. Fowler (1894).

AIDE-DE-CAMP (Fr. for camp-assistant or, perhaps, field-assistant), an officer of the personal staff of a general, who acts

as his confidential secretary in routine matters. On Napoleon's staff such officers were frequently of high military qualifications, and acted both as his "eyes" and as the interpreters of his mind to subordinate commanders, even on occasion exercising a delegated authority. But in modern times, particularly in the British army, they have usually been of very junior rank and their duties largely social. In Great Britain the office of aide-de-camp to the king is given to senior officers as a reward or an honorary distinction. In many foreign armies the word *adjutant* is used for an aide-de-camp, and *adjutant-general* for a royal aide-de-camp. The common abbreviation for aide-de-camp in the British service is "A.D.C.," and in the United States "aid." Civil governors, such as the lord lieutenant of Ireland, have also, as a rule, officers on their staffs with the title and functions of aides-de-camp. The aide-de-camp of the governor of a State in the United States has the title of colonel.

AIDIN. (1) A vilayet in the south-west of Asia Minor including the lower part of the Maeander valley. (2) The principal town of the vilayet about 70m. E.S.E. of Smyrna. It was taken by the Seljuks, Aidin and Mentesh, late in the 13th century, and about 1390, when ruled by Isa Bey, a descendant of the first-named, acknowledged Ottoman suzerainty. In the Seljuk period it was only a secondary city under the provincial capital, Tireh. In the 17th century it came under the power of the Karasmans of Manisa and remained so till about 1820. Aidin is on the Smyrna-Dineir railway. On a neighbouring height are still to be seen the ruins of the ancient *Tralles* (q.v.). Aidin itself suffered severely in the Greco-Turkish conflict of 1919–1922. Pop. (1927), 70,307.

AIDONE, a town of Sicily, in the province of Caltanissetta, about 22m. E.S.E. of the town of that name. Pop. (1921), 7,598. There are ruins of an ancient city on Mte. Serra Orlando near by. Aidone has some interesting 14th-century churches. (See E. Mauceri in *L'Arte*, 1906–17.)

AIDS, a term of mediaeval finance, were part of the service due to a lord from his men, and appear to have been based upon the principle that they ought to assist him in special emergency or need. The occasions for demanding them and the amount to be demanded would thus be matters of dispute, while the loose use of the term to denote many different payments increases the difficulty of the subject.

Both in Normandy and in England in the 12th century the two recognized occasions on which, by custom, the lord could demand "aid" were (1) the knighting of his eldest son, (2) the marriage of his eldest daughter; but while in England the third occasion was, according to Glanvill, as in Normandy, his payment of "relief" on his succession, it was, according to the Great Charter (1215), the lord's ransom from captivity. By its provisions, the king covenanted to exact an "aid" from his barons on these three occasions alone—and then only a "reasonable" one—except by "the common counsel" of his realm. Enormous importance has been attached to this provision, as establishing the principle of taxation by consent, but its scope was limited to the barons and the City of London, and the word "aids" was omitted from subsequent issues of the charter. The barons, on their part, covenanted to claim from their feudal tenants only the above three customary aids. The last levy by the Crown was that of James I. on the knighting of his eldest son (1609) and the marriage of his daughter (1613).

From at least the days of Henry I. the term "aid" was also applied (1) to the special contributions of boroughs to the king's revenue, (2) to a payment in lieu of the military service due from the Crown's knights. Both these occur on the pipe roll of 1130, the military payment as *auxilium militum* (and possibly as *auxilium comitatus*). The borough "aids" were alternatively known as "gifts" (*dona*), resembling in this the "benevolences" of later days. When first met with, under Henry I., they are fixed round sums, but under Henry II., as the *Dialogue on the Exchequer* explains, they were either assessed on a population basis by Crown officers or were sums offered by the towns and accepted by them as sufficient. In this case the townsfolk were collectively responsible for the amount.

Aids and the Great Charter.—The Great Charter, as before stated, extended specially to London the limitation on baronial "aids," but left untouched its liability to tallage, a lower and more arbitrary form of taxation, which the towns shared with the Crown's demesne manors, and which London resisted in vain. The two exactions, although distinct, have to be studied together, and when in 1296–97 Edward I. was forced to his great surrender, he was formerly supposed by historians to have pledged himself, under *De tallagio non concedendo*, to levy no tallage or aid except by common consent of his people. It is now held, however, that he limited this concession to *aides*, *mises* and *prises*, retaining the right to tallage. Eventually, by a statute of 1340, it was provided that the nation should not be called upon "to make any common aid or sustain charge" except by consent of parliament. The aids spoken of at this period are of yet another character, namely, the grant of a certain proportion of all "movables" (*i.e.*, personal property), a form of taxation introduced about 1188 and of rapidly increasing importance. These subsidies were conveniently classed under the vague term "aids," as were also the grants made by the clergy in convocation, the term covering both feudal and non-feudal levies from the higher clergy and proportions not only of "movables" but of ecclesiastical revenues as well.

The "knight's aid" of 1130 spoken of above is probably identical with *auxilium exercitus* mentioned in the oldest customs of Normandy, where the phrase appears to represent what was known in England as "scutage." Even in England the phrase "*quando Rex accipit auxilium de militibus*" occurs in 1166 and appears to be loosely used for scutage.

The same loose use enabled the early barons to demand "aid" from their tenants on various grounds, such as their indebtedness to the Jews, as is well seen in the Norfolk fragments of returns to the Inquest of Sheriffs (1170).

Sheriff's aid was a local payment of a fixed nature paid in early days to the sheriff for his service. It was the subject of a hot dispute between Henry II. and Becket in 1163.

AIGRETTE, the long back plumes which the egret (*q.v.*) assumes in the breeding season, the use of which as ornaments in

women's headdresses has become rare, owing to the protests of humanitarians on account of the cruelty involved in slaughtering the birds and leaving their young to starve. The name is also given to any similar ornament, in gems, etc., to the insignia of rank of colonels in the French army and, in science, to feathery excrescences such as the *pappus* of the dandelion and the luminous rays seen diverging from the moon's edges in solar eclipses.

BY COURTESY OF THE CHAMBER OF COMMERCE OF THOMASVILLE, GA.

EGRETS ON A SOUTHERN RESERVE ESTABLISHED AND MAINTAINED BY THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

AIGUES-MORTES, a town of south-east France, department of Gard, 25m. S.S.W. of Nîmes on a branch line of the P.L.M. railway. Population (1926) 3,411. It occupies an isolated position in the marshy plain at the western extremity of the Rhone delta, 2½m. from the Gulf of Lions. Louis IX. embarked from Aigues-Mortes in 1248 and 1270 for the 7th and 8th crusades, and developed the town. The mediaeval fortifications which surround it are of great interest. They form a parallelogram 596yd. long by 149yd. broad and consist of crenellated walls from 25 to 36ft. in height, dominated by towers, of which the Tour de Constance (N.W.), built by Louis IX., was used as a prison for Protestants after the revocation of the Edict of Nantes. The fortifications were completed under Philip III. To further the prosperity of the town a most liberal charter was granted to it, and in addition the trade of the port was artificially fostered by a

decree requiring that every vessel navigating within sight of the lights should put in there. This ordinance remained in force till the reign of Louis XIV. The town, although steadily decreasing in population, remains important historically as an outstanding example of mediaeval city planning. Aigues-Mortes is the meeting-place of several canals connecting with Beaucaire, Cette, the Lesser Rhone and the Mediterranean. Fishing and the manufacture of soda are industries, with trade in coal, fruits and wine. In the surrounding country there are important vineyards, which are preserved from disease by periodical submersion.

AIGUILLE (Fr. for needle), the sharp jagged point above the snow-line formed by a part of a mountain which has been split by frost action along joints or planes of cleavage with sides too steep for snow to rest upon them. Aiguilles are thus the forms left from the splitting up of the high ridges with "house-roof" structure into detached pinnacles. (See *ARÊTE*.)

AIGUILLON, EMMANUEL ARMAND DE WIGNEROD DU PLESSIS DE RICHELIEU, Duc d' (1720–1782), French statesman, nephew of the maréchal de Richelieu, was born on July 31, 1720. He was a member of the so-called *parti dévot*, the faction opposed to Madame de Pompadour, to the Jansenists, and to the parlement. In 1753 he was appointed commandant (governor) of Brittany and was engaged in constant disputes with the Breton parlement, in 1768 returning to court, where he resumed his intrigue with the *parti dévot* and finally obtained the dismissal of the minister Choiseul (Dec. 24, 1770). When Louis XV., acting on the advice of Madame Dubarry, reorganized the government with a view to suppressing the resistance of the parlements, d'Aiguillon was made minister of foreign affairs, Maupeou and the Abbé Terray (1715–1778) also obtaining places in the ministry. D'Aiguillon was blamed for having provoked the *coup d'état* of Gustavus III., king of Sweden, in 1772, although the instructions of the comte de Vergennes, the French ambassador in Sweden, had been written by the minister, the duc de la Vrillière. D'Aiguillon, however, could do nothing to rehabilitate French diplomacy; he acquiesced in the first division of Poland, renewed the Family Compact, and, although a supporter of the Jesuits, sanctioned the suppression of the society. After the death of Louis XV. he quarrelled with Maupeou and with the young queen, Marie Antoinette, who demanded his dismissal from the ministry (1774). He died, forgotten, in 1782.

See *Mémoires du Ministère du duc d'Aiguillon* (3rd ed., 1792), probably written by J. L. Soulavie. On d'Aiguillon's governorship of Brittany see Carré, *La Chalotais et le duc d'Aiguillon* (1893); Marion, *La Bretagne et le duc d'Aiguillon* (1898); and Barthélemy Pocquet, *Le Duc d'Aiguillon et La Chalotais* (1901–02). The three last have full bibliographies. See also Flammermont, *Le Chancelier Maupeou et les parlements* (1883); Frédéric Masson, *Le Cardinal de Bernis* (1884).

AIGUILLON, MARIE MADELEINE DE WIGNEROD DU PONT DE COURLAY, DUCHESSE D' (1604–75), daughter of Cardinal Richelieu's sister. In 1620 she married a nephew of the Constable de Luynes, Antoine de Beauvoir du Roure, Sieur de Combalet, who died in 1622. In 1625, through her uncle's influence, she was made a lady-in-waiting (*dame d'atour*) to the queen-mother, and in 1638 was created duchess of Aiguillon. After the death of the cardinal (1642) she withdrew from the court, and devoted herself entirely to works of charity. She helped St. Vincent de Paul to establish the hospital for foundlings, and also took part in organizing the General Hospital and several others in the provinces. She died on April 17, 1675. Corneille dedicated to her his tragedy of *Le Cid*.

See E. Fléchier, *Oraison funèbre de Mme. Marie de Wignerod, duchesse d'Aiguillon*; Bonneau-Avenant, *La duchesse d'Aiguillon* (1879); *Mémoires de Saint-Simon*, ed. by A. de Boislisle (1879 et seq.).

AIGUN (49° 58' N. 127° 35' E.) a treaty port on the south bank of the Amur in Northern Manchuria on the extreme north-eastern frontier of China. It lies on the opposite bank to, but about 20 miles below, the Russian city of Blagovyeshchensk, for which it serves as an entrepôt. Its trade is concerned primarily with the shipping of Mongolian cattle and meat and Manchurian grain and flour across the river to Blagovyeshchensk. But, since it was burnt down in 1900 during the Boxer troubles, this func-

tion has passed to Ta-hei-ho T'an which lies immediately opposite Blagovyeschensk. The trade of Aigun is becoming more and more local and what general traffic it once had has been diverted from the Amur to the Chinese Eastern railway which offers a more direct route between Manchuria and the better-peopled parts of Siberia. Its total trade in 1926 amounted to Hk.Tls.-2,069,279. The Treaty of Aigun (1858) was one of a series of treaties which attempted to define the boundaries between the Chinese and Russian Empires.

AIKEN, a city of South Carolina, U.S.A., 17 m. E.N.E. of Augusta, Ga., on the highest point between Augusta and Charleston, 565 ft. above sea-level; the county seat of Aiken county. It is on Federal highways 1 and 78 and the Southern railway, and is connected with Augusta by an electric line. The resident population is small (4,103 in 1920, 2,286 negroes; 1930, 6,033) but it is greatly increased by visitors during the winter, spring and autumn, for Aiken is a health and pleasure resort of high repute. The climate is unusually dry and equable, and the air is filled with fragrance from the forests of yellow Southern pine. There are many luxurious private estates and country clubs, besides hotels and apartments. Fox-hunting, pigeon-shooting, riding, polo, tennis and golf are popular sports. With its seven polo fields, Aiken has been adopted as the winter training-ground for this game.

Aiken was settled early in the 19th century and was incorporated in 1835. It was on the line of one of the earliest railways, and was named after the first president of that road, William Aiken (1806-87), who was governor of the State (1844-47).

AIKIN, JOHN (1747-1822), English physician and author, was born at Kibworth-Harcourt on Jan. 15, 1747, and died at Stoke Newington, London, on Dec. 7, 1822. He practised as a consulting physician in London from 1792 onwards, but gradually became absorbed in literary pursuits. Aikin and his sister, Anna Letitia Barbauld, wrote popular books which had a great vogue. Their admirable miscellany, *Evenings at Home* (1792-95) was translated into many European languages. Aikin's voluminous works include *General Biography* (1799-1815), and *Lives of John Selden and Archbishop Usher* (1812).

His daughter, **LUCY AIKIN** (1781-1864), born at Warrington on Nov. 6 1781, wrote several books for children, including versions of classical stories written in monosyllables. She also wrote: a novel, *Lorimer* (1814); *Memoirs of the Court of Queen Elizabeth* (1818); *Memoirs of the Court of James I.* (1822); *Memoirs of the Court of Charles I.* (1833) and a *Life of Addison* (1843). Miss Aikin died at Hampstead, where she had lived for 40 years, on Jan. 29 1864.

See a *Memoir of John Aikin, with selections of his miscellaneous pieces* (1823), by his daughter; and the *Memoirs, Miscellanies and Letters of Lucy Aikin* (1864), including her correspondence (1826-42) with William Ellery Channing, edited by P. H. Le Breton.

AILANTHUS (more correctly *ailantus*, from *ailanto*, an Amboyna word probably meaning "Tree of the Gods," or "Tree of Heaven"), a genus of trees belonging to the family Simarubaceae. The best known species, *A. glandulosa*, Chinese sumach or tree of heaven, is a handsome, quick-growing tree with spreading branches, and large compound leaves, resembling those of the ash, and bearing numerous pairs of long pointed leaflets. The small greenish flowers are borne on branched panicles; and the male ones are characterized by having a disgusting odour. The fruits are free in clusters, and each is drawn out into a long wing with the seed in the middle. The wood is fine grained and satiny. The tree, which is a native of China and Japan, was introduced into England in 1751 and is a favourite in parks and gardens. It has been extensively planted in the eastern United States where it is one of the few trees which will grow in smoky manufacturing districts. Two other species, *A. imberiflora* and *A. punctata* are important Australian timber-trees; *A. excelsa* is common in India.

AILANTHUS MOTH (*Philosamia cynthia*), a large silk-spinning moth inhabiting China. The larvae feed on the leaves of the ailanthus tree and yield a silk more durable and cheaper than mulberry silk, but inferior to it in fineness and gloss. The moth measures about 5 in. across, and is olive-brown in colour

with a whitish spot and a white and purplish transverse bar on each wing. It was introduced with its food-tree into the eastern United States where it is now common.

AILERON, a movable part of the wing of an aeroplane (*q.v.*) situated at or near the wing tips as shown in fig. 1. They are so connected to the control column that a movement of it, e.g., to the right (or a corresponding rotation of the control

FIG. 1.—NORMAL TYPE OF AILERON
The banking of an aeroplane in turning is brought about by two ailerons, one on the rear edge of each wing. One goes up as the other goes down

wheel), raises the aileron on the right wing and lowers that on the left wing, causing the aeroplane to bank for a turn to the right.

Ailerons of the type shown in fig. 1 are effective in normal flight but when the aeroplane is stalled they become ineffective and a possible source of danger. As the result of research initiated by the Aeronautical Research committee a form of aileron has been developed practically free from this defect. The part of the wing covered by the aileron is "slotted" on the principle invented by F. Handley-Page (*see* AEROPLANE). Fig.

FIG. 2.—AILERON COMBINED WITH HANDLEY-PAGE SLOTTED WING
The purpose of this auxiliary wing is to remove one of the most serious risks of flying. In stalling the ailerons become ineffective. By this device the "slot" opens automatically when the wing stalls and this renders the aileron effective. The illustration shows a right wing seen from below

2 shows one form. The universal adoption of some device of this kind is of vital concern to the future of flying, since it will remove one of the most serious risks.

See AERONAUTICS.

AILLY, PIERRE D' or PETRUS DE ALLIACO (1350-1420), French churchman and schoolman, was born at Compiègne and studied at the College of Navarre of the University of Paris. He became master of the college in 1384 and later obtained the highest dignity in the university, the chancellorship of Notre Dame. John Gerson was one of Ailly's pupils and his lifelong friend. The two men played an important part in the later history of the papal schism. Pierre d'Ailly acted as spokesman of the university before the king's council (May 20 1381) with the proposal that the best way of ending the scandal of the existence of two popes, Urban VI. at Rome and Clement VII. at Avignon, was the summoning of a general council. The suggestion was unacceptable and Ailly retired from Paris for some time. As master of the College of Navarre he was twice sent by the university on missions to Clement VII., and on the death of that pope, he was sent by the king to congratulate Clement's successor, Benedict XIII. His acceptance of that mission displeased the university, which was already beginning to demand the resignation of both popes as a preliminary to the re-unification of the church. Suspicion of his attitude was deepened by his nomination by Benedict XIII. as bishop of Le Puy (1395) and then bishop of Cambrai (1397). At the ecclesiastical council, held in Paris in 1406, Ailly, by the king's order, defended Benedict XIII., and it was not until the convocation of the general Council of Pisa (1409) that he forsook Benedict's cause and returned to the point of view of the University of Paris, of which he had been the champion before his preferment. He and Gerson urged that the unity of the church could only be restored by a general council which, in case of schism, would be supreme and legitimate even though it were not convoked by the pope. The nominee of the Council of Pisa died within a year. His successor, John

XXIII., gave Ailly the bishopric of Orange and made him a cardinal. Nevertheless Ailly was one of the most formidable adversaries of John XXIII. at the Council of Constance (Nov. 1414–April 1418). He maintained that, as the decisions of the Council of Pisa had not been accepted and there were now three “popes,” it was necessary to begin *de novo* and treat the claims of all three alike, and he made serious depositions against John. The theory put forward by Ailly and Gerson that the general council had jurisdiction over the pope himself was a dangerous one, and, according to later decisions, even heretical; but both men were seeking an outlet from an impossible situation. Ailly found in the end an ingenious compromise on the rights of the Sacred College and the council and the schism was healed by the appointment of Martin V.

During the Council of Constance, Ailly had earned the hatred of the Anglo-Burgundians by trying to reduce the power of the English by contesting their right to form one of the four separate nations. He was compelled to retire to Avignon, where he died on Aug. 9 1420.

Pierre d'Ailly's written works are numerous. Many of them were published with the works of Gerson (by Ellies du Pin, Antwerp, 1706); others appeared in the 15th century, probably at Brussels; and there are many treatises and sermons still unpublished. In philosophy he was a nominalist.

(1894); N. Valois, *La France et le grand schisme d'Occident* (1896–1902); and *Bibliothèque de l'école des chartes*, vol. lxx., p. 557–574 (1904).

AILSA CRAIG, an island rock at the mouth of the Firth of Clyde, 10m. W. of Girvan, Ayrshire, Scotland. It is of conoidal form, with an irregular elliptic base, and rises abruptly to a height of 1,097ft. The only side from which the rock can be ascended is the east, the other sides being for the most part perpendicular, and generally presenting lofty columnar forms, though not so regular as those of Staffa. The island is composed of micro-granite with riebeckite, of great interest on account of the rare occurrence of this type in Britain. It is fine-grained and of a greyish colour, and may be of Tertiary age. Pebbles of this rock were carried far south (e.g. to Welsh shores) by glaciers of the Ice age. The rock is a favourite material for curling-stones. Hence curling-stones are popularly known as “Ailsas” or “Ailsa Craigs.” The rock is also used for paving stones. A columnar cave exists towards the north side of the island, and on the east are remains of a tower. Two springs occur and some scanty grass affords subsistence to rabbits, and, on the higher levels, to goats. The precipices have large breeding colonies of gannets and other sea birds which spend the winter months at sea. A lighthouse on the south side flashes a light visible for 13 miles.

AIMAK, the name of nomadic or semi-nomadic Mongolian tribes inhabiting the north and north-west Afghan highlands north of Herat. *Aimak* is a Mongolian word meaning “clan” or “section of a tribe.” They were originally known as “chahar (the four) eimaks,” because there were four principal tribes: the Taimani, the Ferozkhoi, the Jamshidi and the Hazara. They number about 250,000, and speak a dialect akin to Kalmuck. They are Sunnite Mohammedans.

AIMARD, GUSTAVE, the pen-name of OLIVIER GLOUX (1818–83), French novelist, who was born in Paris Sept. 13, 1818, and died there June 20, 1883. He made use of the materials collected in a roving and adventurous youth and early manhood in numerous romances in the style of J. Fenimore Cooper. Among the best of them are: *Les Trappeurs de l'Arkansas* (1858); *La grande fibuste* (1860); *Nuits mexicaines* (1863); *La Forêt vierge* (1870).

AIMOIN (c. 960–c.1010), French chronicler, spent the greater part of his life in the monastery of Fleury. His chief works are: *Historia Francorum* or *Libri V. de gestis Francorum*, a history of the Franks from the earliest times to 633, which was continued by other writers and brought down to the middle of the 12th century; a life of Abbo, abbot of Fleury; and books ii. and iii. of the *Miracula S. Benedicti*.

BIBLIOGRAPHY.—The *Historia* is printed in *Monumenta Germaniae historica: Scriptores*, Band xxvi.; and the *Vita* and the *Miracula* in Mabillon, *Acta sanctorum ordinis S. Benedicti* (Paris, 1668–1701). Some fragments by another Aimoin, a monk of St. Germain-des-Prés, are printed in *Historiae Francorum Scriptores*, tome ii. (1639–49). AIN, a department of eastern France, formed from Bresse, the Pays de Dombes on the lowland and the Pays de Gex, Valromey and Bugey among the high parallel scarps of the Jura reaching south to the Rhone between Geneva and Lyons. Area 2,248 sq.m. Pop. (1926) 317,195. The name is that of the river which roughly separates the two first from the other districts, running north to south at first between outer hill ranks and then along the foot of the highland to join the Rhone. The western boundary is the Saône, the southern the Rhone, the eastern Switzerland and the northern the departments of Saône-et-Loire and Jura, the boundary over against the latter being closely linked with that of old between Burgundy and Franche Comté. The Pays de Gex includes some of the highest Jura scarps (Crêt de la Neige 5,653-ft.), the Pays de Valromey flanks on the west the deep Rhone gorge below Bellegarde, the Pays de Bugey is the south-pointing triangle of the Rhone focussing on Belley. West of the hills, Bresse occupies the fertile north part of the department and is effectively drained to the Saône, thus contrasting with the Pays de Dombes, mantled in boulder clay and possessing endless pools and marshes with, still, a good deal of consequent malarial trouble. The summers are warm in the lowland but the winters, generally, are sharp, the rainfall rises well above 1 metre per annum in the highland. The farms of Bresse are famous for pigs and poultry and the latter (especially geese) are also bred, in Dombes, which also raises horses. In the Jura hill country, pastures feed sheep and cattle from which cheese is produced, while many slopes are well forested. Bresse produces considerable cereal and other crops but the rest of the department is thus concerned mainly with stock-raising or with activities connected with its forests (of fir and oak) or with extensions of the silk industry from Lyons just beyond the south-west corner of the department, thanks to the water power available from the rivers among the gorges of the limestone country. Bourg is the capital of the department; the three arrondissements of which take their names from Bourg, Belley (the seat of a bishop in the archiepiscopal province of Besançon) and Nantua. The departmental appeals are heard at the court of Lyons and the department is also under Lyons educationally. Bourg (*q.v.*) is a market town specially known in connection with the famous church of Brou, wrongly described in Arnold's well known poem as being in Savoy. Among silk towns one may mention Jujurieux, Tenay, St. Rambert, St. Bernard en Bugey; Bellegarde and St. Rambert make wood pulp; and Oyonnax, a rather larger town than several of the others, north of Nantua, makes articles in wood and horn and is specially well known for its combs. Seyssel, on the far east, yields asphalt and many parts of the department give building stones, cement or potter's clay. There is a good tourist industry for winter sports, angling, etc., and some of the gorges and ridges are very striking; near Bellegarde, at the Perte du Rhone, that great river formerly disappeared down a fissure. Though the main P.L.M. railway from Dijon to Lyons lies west of the Saône, and so outside the department, the main line from Paris to Geneva runs through Bourg and Ambérieu to Bellegarde; both the Saône and the Rhone are navigable for considerable lengths along the confines of the department.

AINGER, ALFRED (1837–1904), English divine and man of letters, was born in London on Feb. 9, 1837, the son of an architect. He was educated at King's College, London, and at Trinity College, Cambridge, and was ordained in 1860 to a curacy at Alrewas, near Rugeley. His connection with the Temple Church, in London, began in 1866, when he was appointed reader; and in 1894 he succeeded Dr. Vaughan as master. In 1887 he was presented to a canonry in Bristol cathedral, and he was chaplain-in-ordinary to Queen Victoria and King Edward VII. He died on Feb. 8, 1904. Canon Ainger's gentle wit and humour, his generosity and lovable disposition, endeared him to a wide circle. In literature his name is chiefly associated with his sympathetic appreciation of Charles Lamb and Thomas Hood.

His works include: *Charles Lamb* (1882) and *Crabbe* (1903) in the "English Men of Letters" series; editions of Lamb's *Essays of Elia* (1883) and of his *Letters* (1888; 2nd ed., 1904), of the *Poems* (1897) of Thomas Hood, with a biographical introduction; *The Life and Works of Charles Lamb* (1899-1900); articles on Tennyson and Du Maurier in the *Dictionary of National Biography*; *The Gospel and Human Life* (1904), sermons; *Lectures and Essays* (1905), edited by the Rev. H. C. Beeching.

See Edith Sichel, *The Life and Letters of Canon Ainger* (1906).

AINHARDUS: see EINHARD.

AINMÜLLER, MAXIMILIAN EMMANUEL (1807-1870), German artist and glass-painter, was born at Munich on Feb. 14, 1807. In 1828 he was appointed director of the newly-founded royal painted-glass manufactory at Munich. The method which he gradually perfected there was a development of the enamel process adopted in the Renaissance, and consisted in actually painting the design upon the glass, which was subjected, as each colour was laid on, to carefully-adjusted heating. The earliest specimens of Airmüller's work are to be found in the cathedral of Ratisbon. With a few exceptions, all the windows in Glasgow cathedral are from his hand. Specimens may also be seen in St. Paul's cathedral, and Peterhouse, Cambridge, and Cologne cathedral contains some of his finest productions. Airmüller had considerable skill as an oil-painter, especially in interiors. He died on Dec. 9, 1870.

AINSWORTH, HENRY (1571-c. 1622), English Nonconformist divine and rabbinical scholar, was born at Swanton Morley, Norfolk. He was a scholar of Caius College, Cambridge, joined the Puritan party in the church, and eventually the Separatist. Driven abroad in the persecution of 1593, he found a home in "a blind lane at Amsterdam." He acted as "porter" to a scholarly bookseller in that city, who, on discovering his skill in Hebrew, enabled him to continue his Hebrew studies. When part of the London church, of which Francis Johnson (then in prison) was pastor, reassembled in Amsterdam, Ainsworth was chosen as their doctor or teacher.

In 1596 he drew up a confession of their faith, which he re-issued in Latin in 1598. Johnson joined his flock in 1597, and in 1604 he and Ainsworth composed *An Apology or Defence of such true Christians as are commonly but unjustly called Brownists*. In 1610 he was forced reluctantly to withdraw, with a large part of their church, from F. Johnson and his adherents on a question of church government, Ainsworth taking the more congregational view. (See CONGREGATIONALISM.) But in spirit he remained a man of peace. The fruit of his rabbinical learning appeared in his *Annotations—on Genesis* (1616); *Exodus* (1617); *Leviticus* (1618); *Numbers* (1619); *Deuteronomy* (1619); *Psalms* (including a metrical version, 1612); *Song of Solomon* (1623). These were collected in folio in 1627, and again in 1639. From the outset the *Annotations* took a commanding place, especially among Continental scholars.

BIBLIOGRAPHY.—John Worthington's *Diary* (Chetham Society), by Crossley, i. 263-266; works of John Robinson (1851); H. M. Dexter, *Congregationalism of the Last Three Hundred Years* (1880); W. E. A. Axon, *H. Ainsworth, the Puritan Commentator* (1889); F. J. Powicke, *Henry Barrow and the Exiled Church of Amsterdam* (1900); J. H. Shakespeare, *Baptist and Congregational Pioneers* (1906).

AINSWORTH, ROBERT (1660-1743), English schoolmaster and author, was born at Eccles, near Manchester, in Sept. 1660. Ainsworth's name is associated with his Latin-English dictionary, begun in 1714 and published in 1736 as *Thesaurus lingue Latine compendarius*. He died in London, April 4, 1743.

AINSWORTH, WILLIAM HARRISON (1805-1882), English novelist, was born at Manchester, Feb. 4, 1805. He was educated for the law, but at the age of 21 he married a daughter of John Ebers, the publisher, and followed his father-in-law's profession for a short time. A novel called *Sir John Chiverton*, in which he had a share, won the praise of Sir Walter Scott, and he turned to novel-writing. *Rookwood* (1834), with its description of the ride of Dick Turpin to York, had an immediate success. He published about 40 "historical" novels, of which the

best known are *Jack Sheppard* (1839), *The Tower of London* (1840), *Old St. Paul's* (1841) and *Windsor Castle* (1843). He edited *Bentley's Miscellany*, in which *Jack Sheppard* was published as a serial, and in 1842 he became proprietor of *Ainsworth's Magazine*. In 1853 it ceased to appear, and Ainsworth bought the *New Monthly Magazine*. He died at Reigate, Jan. 3, 1882.

See S. M. Ellis, *William Harrison Ainsworth and his Friends* (London, New York, 1911).

AINTAB (anc. DOLICHE), a city of Anatolia just outside French mandated territory, pop. about 60,000 (two-thirds are Muslim, mainly of Turkoman origin and there are 15,000 Armenians). In ancient times (2nd Mil. B.C.) Aintab was in the Hittite area and is probably of Hittite origin. Duluk, the site of *Doliche*, famous for the worship of Zeus Dolichenus (Baal), is marked by a mound two hours distant to the north-west. In Crusading times its strong castle (*Hamtab*) was a strategic point of importance and was captured by Saladin in 1183. It served as the last base of Ibrahim Pasha before his victory over the Turks at Nezib, 25m. to the north-east (1839). In the winter of 1920-21 the armed opposition of the Turkish nationalists to the French occupation of north Syria centred in Aintab which became the "Verdun of Anatolia." After an investment lasting six months, despite determined Turkish efforts to relieve it, the city surrendered to the French troops. France returned it to Anatolia under the Angora Treaty of Oct. 30, 1921.

The modern city stands high (3,500ft.) in the open, treeless valley of the Sajur, a tributary of the Euphrates, some 65m. N.E. of Aleppo. Important educational and medical work is carried on by the American Mission Board in their college (founded 1874) and girls' seminary. There is also a Franciscan mission. Manufactures include striped dress materials (the chief of which is a mixture of silk and cotton), black goats' hair cloth for tents, morocco leather (*sakhtiyan*) made from goats' skins (it is estimated that nearly 400,000 are tanned here annually), "Aleppo soap" made from olive oil, *Pekmez*, a sweet paste made from grapes, and the dyeing of yarns. The exports include pistachio nuts, tobacco, cotton and cereals.

AINU, who are racially closely akin to, if not identical with, the Neolithic inhabitants of Japan (see JAPAN, Section, *History*)

are now very reduced in numbers and live in Hokkaido, the northern island of Japan, in part of Saghalien, and have kinsfolk in the Ryukyu islands (*q.v.*). They are dwindling fast and are unable to compete with the advance of Japanese civilization. Physically they are probably the remains of an old Proto-Nordic population once widely spread over Northern Asia, and are certainly the relics of a very old human stock. Their culture recalls in many ways stone age man and they have preserved the very earliest stage of agriculture, when the men are still hunters but the women have developed beyond the mere collecting stage and are beginning actually to plant crops.

The Ainu religion is closely akin to the animistic religion practised by various primitive peoples of northern Asia, and they are particularly liable to that peculiar kind of religious ecstasy known as Arctic hysteria. One of their special cults is that of the bear. This animal is caught as a cub, and is carefully tended by the women who will even suckle it. At about three years old the bear is sacrificed with elaborate ceremony. In most of the Ainu villages, the special wooden cages in which the bears are kept can be seen. Prominent also in the villages are sticks which have been whittled (*inao*) and the shavings left on. The sticks are stuck in the ground and have a religious significance.

AN AINU VILLAGE CHIEF

The Ainu are now under Japanese rule, but in former times their affairs were administered by hereditary chiefs, three in each village

AIR, the atmosphere that surrounds the earth. With the development of analytical and especially of pneumatic chemistry, the air was recognized not to be one homogeneous substance, as was long supposed, and different "airs," or gases, came to be distinguished. At the end of the 18th century oxygen gas was known as *dephlogisticated air*, nitrogen or azote as *phlogisticated air*, hydrogen as *inflammable air*, carbonic acid gas as *fixed air*. The name is now ordinarily restricted to atmospheric air (see **ATMOSPHERE**). The sense of atmosphere or environment may have led to the further use of the word "air" to mean "manner" or "appearance"; and so to its employment (cf. Lat. *modus*) in music for "melody." (See **ARIA**.)

AIR or **ASBEN**, a country of West Africa, lying between 15° and 19° N. and 6° and 10° E. It is within the Sahara, of which it forms one of the most fertile regions. The northern portion of the country is mountainous, some of the peaks rising to a height of 5,000ft. Richly wooded hollows and extensive plains lie between the hills. The mimosa, the doum palm and the date are abundant. Some of the plains afford good pasturage for camels, asses, goats and cattle; others are desert tablelands. The country generally is of sandstone or granite formation, with occasional trachyte and basaltic ranges. There are no permanent rivers; but during the rainy season, from August to October, the water-courses in the hollows of the mountains are converted into broad and rapid streams. Numerous wells supply the people and their cattle. To the south of this region lies a desert plateau, 2,000ft. above sea-level. Still farther south is the fairly fertile district of Damerghu, of which Zinder is the chief town. There is cultivation in the neighbourhood of the villages. Millet, dates, indigo and senna are the principal products.

Air was called Asben by the native tribes until they were conquered by the Berbers. The present inhabitants combine the finer traits of the Berbers with negro characteristics. The sultan of Air is much dependent on the chiefs of the Tuareg tribes inhabiting a vast tract of the Sahara to the north-west. A large part of his revenue is derived from tribute exacted from the salt caravans. Since 1890 Air has been included in the French sphere of influence in West Africa.

Agades, the capital of the country, which has a circuit of 3½m., is built on the edge of a plateau 2,500ft. high, said to have been founded by the Berbers to serve as a secure magazine for their extensive trade with the Songhai empire. The language of the people is a dialect of Songhai. In former times Agades had a great trade, with a population of about 50,000. Since the beginning of the 16th century the prosperity of the town has, however, gradually declined.

AIRAY, HENRY (1560?–1616), English Puritan divine, was born at Kentmere, Westmorland, but no record remains of the date of either birth or baptism. He died on Oct. 6, 1616. His character as a man, preacher, divine, and as an important ruler in the university, will be found portrayed in the Epistle by John Potter, prefixed to his *Commentary on the Epistle to the Philippians* (1618). He must have been a fine specimen of the more cultured Puritans—possessed of a robust common sense in admirable contrast with some of his contemporaries.

AIR-BLADDER, the name given to a structure present in all bony fishes (Teleosts) and homologous with the lungs of land vertebrates. The functions of this organ, which contains gas having a high percentage of oxygen, are obscure; hydrostatic uses have been attributed to it with doubtful validity. In some fishes (especially Siluroidea, *q.v.*), it is connected with the internal ear by a chain of bones, the Weberian ossicles, and in these forms it is possibly concerned with hearing. It usually retains a connection with the alimentary canal (except in most Acanthopterygii, *q.v.*), but is normally dorsal to it. (See **FISH**.)

AIRBRUSH, a machine used for applying liquid colouring to a surface by means of compressed air. The use of compressed air for the atomization of liquids has been known for many years, but it is only in the last quarter century that the principle has been successfully applied to the application of varnishes, enamels, lacquers, etc., in commercial and industrial enterprises, and today there is hardly an institution anywhere whose product re-

quires finishing that does not employ this method of application. The early successful use of airbrushes was in the art field, where artists employed them almost exclusively for executing and retouching various kinds of art work.

The airbrush shown in fig. 1 (p. 441) is used in drawing the most delicate hair-line work, as well as photographic retouching. It is a common implement in all large newspaper art departments. Fig. 2 illustrates the next step towards a commercial airbrush, this style being used for decorative and show-card work.

The natural evolution of the airbrush that was used by the artist brought about the present industrial type (fig. 3) which is used in practically every automobile and furniture factory, or any industry applying liquid finishes to their product. This is a universal airbrush, inasmuch as it may be used with any style of fluid supply, gravity (overhead bucket), pressure tank and cup (either syphon or gravity), thus making the airbrush applicable to all purposes. The heads for this type are made in five sizes, all interchangeable, thus adapting the airbrush to all consistencies of material. The production of as high as 5,000 automobiles per day could never have been reached were it not for the airbrush, which makes it possible to coat a body in less than one minute. Fig. 4 shows a modern industrial installation as used for the finishing of furniture, the booth and ventilating equipment being very necessary to carry off the fumes and excess spray.

Fig. 5 illustrates a complete portable airpainting outfit, such as is used in painting a house. With such a machine one man can do more painting than five men with hand brushes, and do it better. Contract painters everywhere now use these machines for all general painting, and particularly are they of tremendous value in painting stucco work. Large railroad companies have adopted this method of painting their bridges, depots and cars, effecting an enormous saving in addition to the fact that they are now able to get this work done in season. This type of machine is made for both electric and gasoline (petrol) engine operation.

Airbrushes are now made to function in every capacity from that of a cement mixture to the most delicate art work.

(H. W. N.)

AIR COMBAT. Combat between aircraft is a new development of war. It is one that will probably become increasingly important, since aircraft have, so far at any rate, proved in war to be the best antidote to aircraft. The most effective way in fact of preventing enemy aircraft from carrying out their object, be it reconnaissance, observation of artillery fire or bombing, is to oppose them in the air with other aircraft.

I. HISTORICAL

The term air combat covers fighting between aeroplanes and between aeroplane and airship. There has been no instance recorded of airship fighting airship.

Early History.—Prior to the outbreak of the World War, none of the belligerents had devoted much attention to air combat. Reconnaissance was regarded as the primary, indeed almost the only, duty of aircraft. There was thus little or no specialization of duties among aeroplanes; in fact it is, broadly speaking, true to say that all the belligerents began the war with one class of aeroplane—a two-seater designed solely for reconnaissance. There were a few single-seaters of high performance, but their rôle was that of fast scouts. As the war went on, specialization appeared, and a class of aeroplane designed specifically for air fighting was evolved, followed by a class of bombing aeroplanes.

Prior to the outbreak of war the British had experimented with machine-guns in aircraft, and firing tests had been carried out in the air. But on the outbreak of war no aeroplane on the Western Front was actually armed with a machine-gun. Rifles, carbines, pistols, shotguns and hand grenades were carried by pilots and observers. The tactics employed in the stray combats that did occur at this time were rudimentary. The pilot simply flew close to the enemy aeroplane, and, when within range, he or his observer blazed away with whatever weapon they happened to be carrying.

In the summer of 1915, all belligerents began to mount machine-

guns in their standard two-seater reconnaissance aircraft, the great majority of which were of the tractor type (*i.e.*, aeroplanes in which the pilot sits behind the engine). In these aeroplanes the gun was usually mounted on a swivelling bar at the back of the observer's seat. The observer could only fire the gun backwards towards the tail of the aeroplane and over the pilot's head. (At that time the observer was always seated in front of the pilot.) The arc of fire was consequently restricted; and it was necessary, owing to the fact that the gun pointed towards the aeroplane's tail, to fly *away* from the enemy aeroplane in order to bring fire to bear upon it.

It was at once apparent that, in order to attack effectively, it was essential to be able to fire *forwards* in the direction in which the aeroplane was flying. The British had already designed an aeroplane embodying this principle. This aeroplane, the Vickers Fighter, was a two-seater of the "pusher" type (*i.e.*, the pilot and observer sat in a nacelle in front of the engine). The observer, who sat in the very front of this nacelle, was armed with a Lewis gun on a swivelling mounting. Two squadrons of these aeroplanes were sent to France in the summer and autumn of 1915 respectively. The machine, however, lacked speed and climbing power, and was soon outclassed by a new type of German aeroplane—the Fokker monoplane.

The Fokker Monoplane (Autumn 1915).—This was a small, fast single-seater, of the tractor type. It was fitted with a

fixed machine-gun firing straight ahead and a synchronizing gear by which the actions of the engine and the machine-gun were so co-ordinated that the gun only fired when the propeller blade was *not* opposite the muzzle of the gun. The pilot aimed the gun by pointing his aeroplane at the enemy. This, the first effective "fighter" aeroplane, began to appear on the Western Front in the autumn of 1915, and by the end of the year had achieved such success as to be practically master of the air.

Meanwhile the Allies had not been idle. Shortly after the advent of the Fokker E.I., the French produced the "Baby" Nieuport, a single-seater tractor biplane with a Lewis gun so fixed on its top-plane as to fire straight ahead outside the arc of the propeller; while early in 1916 the British sent to France the D.H.2, and later the F.E.8. These were small single-seater fighters of the pusher type, in which the pilot operated a Lewis gun on a moveable mounting in the front of the nacelle.

By this time the need for the specialization of functions among aircraft was becoming apparent; and both the Allies and the Germans, besides producing aeroplanes designed solely for air fighting, had, by the beginning of 1916, grouped these aeroplanes into specialist fighting squadrons.

Formation Flying (Spring 1916).—The success of the Fokker monoplane had a direct and immediate effect on the tactics of air combat, and on the design of all types of aeroplanes. As regards tactics, it was responsible for the birth of formation fly-

ing. Towards the end of 1915, owing to the casualties among British and French aircraft, it became the custom to send out two or three aeroplanes to fly in close company for mutual protection, whenever their duties necessitated their penetrating more than a few miles into enemy territory. The German Fokker pilots retaliated by working together in slightly larger formations, so as to have the advantage of numbers on their side. As the war proceeded, by reason of this competition to outnumber the enemy, formations tended to increase in size, until by the end of the war formations of 50 or 60 aeroplanes, working together in close co-operation, were not uncommon.

As formations increased in size and the tactics of fighting in formation developed, individualism in air fighting tended to disappear in favour of co-operation—that is, it was found, as the war went on, to be usually of little use for one pilot to go out alone to search for and shoot down enemy aeroplanes. Not only was he liable to be attacked by a formation of enemy fighters and so outnumbered, but it was also found to be a hazardous business for one man to attack single-handed a close-knit formation of two-seater reconnaissance or bombing aeroplanes.

The System of Offensive Patrols (Summer and Autumn 1916).—By the summer of 1916 therefore the customary British method of employing fighter squadrons was to send them out in small formations of five or six aeroplanes on what were termed “offensive patrols.” These formations flew out over enemy territory, often as far as the enemy aerodromes, with the object of searching for and dispersing enemy fighting patrols, and so affording indirect protection to the British reconnaissance, artillery observation and bombing aircraft. To the French must be given the credit of first employing this system on a wholesale scale. This they did at Verdun in the spring of 1916. But the system was brought to full flower by the British during the battle of the Somme, where its success was so great as to transfer for a time to the Allies the mastery of the air that had been previously won for the Germans by the Fokker monoplane.

Modifications in Design of Two-Seaters (Summer 1916).—In 1916, as a result of the increasing importance of air combat, all belligerents began to devote far more attention not only (as already described) to the development of fighting aircraft and their methods of employment, but also to the design of the two-seater reconnaissance and bombing aeroplanes, and to the tactics by which they could best defend themselves against the attacks of fighting aircraft. Thus there gradually came into vogue a more or less standard “lay-out” for the two-seater reconnaissance and bombing types—a lay-out that has not so far been materially modified. The design that was found to be most effective was a tractor biplane, in which the pilot was seated *in front* of the observer or gunner. The pilot had a fixed machine-gun, firing straight ahead, and a synchronizing gear—an armament in fact similar to that of the fighter pilot. The observer was seated facing backwards, behind the pilot, with a light machine-gun on a swivelling mounting with which he was able to cover an arc of rather more than 180 degrees towards the aeroplane’s tail. Since—for reasons that will be explained later—the usual method of attack in the air is to take the enemy in the rear, the main defence of a two-seater was found to be in the fire of the observer from this rearward gun, supplemented of course, by such tactical manoeuvres as the pilot thought fit to carry out. The first two-seater aeroplane of this type to be used on the Western Front was a British machine, the Sopwith “1½ Strutter,” the first squadron of which was sent to France in the early summer of 1916. Later aeroplanes with a similar lay-out and armament were the British R.E.8, D.H.4, Bristol Fighter and D.H.9; the French Breguet; and many types of German two-seaters, of which the L.V.G. was perhaps the most common.

FIG. 1.—THE SUPERIOR ACCURACY OF FIRE ALONG THE LINE OF FLIGHT

When firing along AB the line of flight, no allowance need be made for the speed of the aeroplane, but when firing any other direction, as CD, this factor has to be taken into account

Germany's Second Period of Mastery (Spring 1917).—

Early in 1917 the Germans made a determined effort to regain the mastery of the air, which they had lost the previous summer on the Somme. They produced two new types of single-seater fighters—the Albatros D.III. and the Halberstadt—which for some months outclassed the fighters of the Allies at that time on the Western Front. Their success was due partly to their superior performance, and partly to the fact that they were armed with two machine-guns, fixed to fire through the propeller, instead of one as heretofore. The Allies, caught short of effective fighters, quickly lost the superiority in the air that they had won the previous year at Verdun and on the Somme. By February 1917 German superiority was clearly marked.

Second Period of Franco-British Superiority.—Once more, however, the pendulum swung. In the spring of 1917 the British brought to the Western Front a new type of single-seater fighter, the S.E.5, followed in the early summer by another fighter, the Sopwith Camel and by two two-seaters of exceptional performance, the D.H.4 and the Bristol Fighter. The French moreover produced an improved Spad. With the machines now at their disposal, the British and French fighting pilots gradually won back for the Allies a measure of superiority in the air that was not lost before the Armistice was signed.

In the last year of the war the tactics of fighting in formation crystallized, and tactical systems were evolved adapted to the peculiarities of the various types of aeroplanes. In the summer of 1918 on the Western Front it was rarely that either fighter or bombing squadrons operated in formations of less than squadron strength; and, as already stated, it was not uncommon for three or four squadrons to work together in one large, but rather loose formation. The tactics customarily employed in the formation fighting of this period have not materially changed and will be described in a later section.

II. THE TACTICS OF AIR COMBAT

Types of Aircraft.—From the point of view of air fighting, aeroplanes fall into two categories—first, aeroplanes designed solely for air fighting, and, secondly, aeroplanes designed primarily for some other duty, such as reconnaissance or bombing.

Aeroplanes in the first category are called “fighters” (U.S. “pursuit planes”; Fr. “avions de chasse”); they are usually single-seaters of great speed and climbing power, armed with two fixed machine-guns firing straight ahead through the propeller by means of a synchronizing gear.

FIG. 2.—SHOWING THE EASIEST TARGET IN AIR COMBAT
In direct line pursuit the pilot of the pursuing machine A is aiming at the equivalent of a stationary target

Among aeroplanes not designed solely for air fighting there is a wide variety in design and lay-out. Broadly speaking, however, they fall into two main classes—single-engine and twin-engine aeroplanes. The modern single-engine machine is usually a tractor biplane of medium size carrying a crew of two, or less frequently three, men. The pilot is seated in front of the gunner, and is armed in the same way as the pilot of a fighter aeroplane with one or two fixed machine-guns firing straight ahead. The gunner or observer sits behind the pilot, facing backwards, and is armed with one or two light machine-guns on a swivelling mounting.

In the case of twin- or multi-engine aeroplanes two gunners are carried; one sits in the very front of the aeroplane’s fuselage and

covers the forward arc; the other sits behind the pilot and covers the rearward arc.

The Manoeuvres Preliminary to an Air Combat.—When two hostile aeroplanes meet, the higher of the two has the advantage. The reason for this is that an aeroplane can descend more quickly than it can ascend. The higher of the two aeroplanes can dive down to its opponent's level in a few seconds; whereas the lower will take several minutes to climb up to the other's height. This is why in air fighting a pilot is constantly striving to outclimb his opponent, since superior height gives him the power to attack at once or to avoid combat altogether, just as he wishes. This also explains why speed and climbing power are such vital factors in "fighter" aircraft, since, if they lack these characteristics, their natural prey, the enemy's bombers and reconnaissance aircraft, will, by coming over high up, be able to avoid combat.

The Tactics of Attack.—A fighter pilot therefore, when on patrol, will always try to get above his opponent. He will then dive to close quarters and attack. His method of attack now requires explanation.

Referring to fig. 1, the first fact to be grasped is that it is easier for the pilot of the aeroplane depicted to hit a target with a gun firing along the line A-B (either forwards or backwards) than with one firing along any other line (e.g., the line C-D). The reason for this is that, when firing along the line A-B, he does not have to take into account the speed of his own aeroplane or the direction in which it is moving with reference to the target. This is an important consideration in view of the high speed of aeroplanes. Generally speaking, therefore, the most effective way to attack a hostile aeroplane is for the pilot to fly towards it and shoot at it with a gun fixed so as to fire straight ahead parallel to the path of his own aeroplane, since by doing so he has to make no allowance for the speed and direction of flight of his own aeroplane.

Now if the enemy aeroplane was a stationary object that could not shoot back the problem of attack would be simple. The attacking pilot would simply fly straight at his target, aiming his gun at it by steering his aeroplane. But the target is not stationary; it is moving in three dimensions at a speed of anything up to 180 m.p.h., and can moreover shoot back. The attacking pilot has therefore two objects—first to attack in such a way that the enemy aeroplane presents a reasonably easy target, and secondly to attack in such a way that the enemy cannot shoot back effectively.

A glance at fig. 2 will show that the easiest target for the pilot of the attacking aeroplane (marked A in the diagram) is an aeroplane flying directly ahead of him and in precisely the same direction as himself.

It will be seen that when the attacking pilot is flying directly behind, and in the same direction as the aeroplane he is attacking, and is shooting at it with a fixed gun firing straight ahead, not only does he have to make no allowance for the speed and direction of flight of his own aeroplane, but he also has to make no allowance for the speed and direction of flight of the enemy aeroplane. In fact he gets a straight shot at the enemy over open sights. It is true that he himself is exposed to a straight shot over open sights from the enemy gunner, firing to the rear. But this can usually be avoided by the attacking pilot placing his aeroplane in such a position (slightly below and to the rear of the enemy aeroplane)

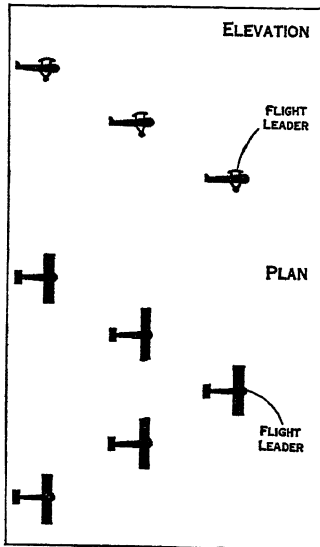

FIG. 3.—FLIGHT OF 5 AEROPLANES FLYING IN FORMATION

The leading aeroplane flies at the lowest elevation, while the second and third lines fly at heights that enable them to keep their leader in full view and catch up easily if they drop behind

that he is concealed from the view of the enemy gunner by the tail-plane of the enemy aeroplane.

While therefore a pilot may attack from any direction—from the front, flank or rear—to confuse an opponent or to break up an enemy formation, he will generally, when he wishes to fire for effect or deliver the *coup de grâce*, fly directly behind the enemy aeroplane, and shoot at it over open sights.

Tactics of Defence.—How will a pilot attacked in this way defend himself? He will rely of course to a certain extent on the accuracy of the gun-fire of his gunner behind him. But over and above this he will have two objects in view at the moment of attack: first to get out of the enemy's line of fire as quickly as possible; and secondly to try and turn the tables and himself become the attacker. There are various alternative manoeuvres by which these two objects may be attained. But it is usually accepted that the most effective manoeuvre is to do a steep, climbing turn. The turn carries the pilot attacked out of the enemy pilot's line of fire in a lateral direction; by climbing on the turn he gains that all important factor—height; and, with the help of the height so gained, he stands a good chance, by means of a second turn and a dive, of turning the tables and himself becoming the attacker.

Fighting in Formation.—The most convenient formation for air fighting is the wedge or "vee" (see figs. 3 and 4).

The reasons why the "vee" is the most suitable shape for a formation of aircraft are first, that all pilots can see the leader in front and so conform readily to his movements; secondly, that each pilot can fire in a forward direction without hitting one of his fellow-pilots, while in the case of two-seaters the gunners can obtain a good concentration of fire in a rearward direction; and lastly that no aeroplane is flying in another's propeller wash.

A formation is usually "stepped" upwards in height from front to rear, i.e., the leader's aeroplane is the lowest; the pilots on either side of him fly slightly higher; while the rear rank of the formation flies higher still.

A formation must not be so small as to be easily overwhelmed by superior numbers, or so large as to be unwieldy. Fifteen aeroplanes are about the maximum number that can be handled in one

formation. When greater numbers than this are required for an operation, it is usual to form two or more separate formations which work together in close co-operation.

The first essential of fighting in formation is that the formation should hang together, and not be split up. Once the formation becomes disintegrated, each aeroplane is liable to be set upon separately by superior numbers and defeat in detail results. Further, the concentration of gun-fire that an organised formation of aeroplanes can bring to bear is far more likely to achieve results than the spasmodic gun-fire of the same number of single aeroplanes working independently of each other.

A consequence of this is that when one formation of aeroplanes meets another (e.g., a formation of fighters meets a formation of bombers), the first

FIG. 4.—FLIGHT OF 9 AEROPLANES IN SQUADRON FORMATION

The formation is spear-headed and is composed of 3 flights of 3 aeroplanes each

object of the attacking formation (the fighters) is to break up the bombers' formation. Once the bombers' formation is broken, each bomber can be dealt with separately by a superior concentration of fighters. Conversely, the bombers' object is to avoid having their formation broken. For this they will rely primarily not on manoeuvre, but on the concentration of fire that their gunners can bring to bear on the fighting formation, as it dives in to attack. In other respects the principles of fighting in formation are similar

to those already alluded to in the case of combat between individual aeroplanes.

Night Fighting.—Aeroplanes can fight at night. The tactics employed are the same as by day, except that aeroplanes do not fly in formation at night. It is moreover far more difficult at night for a fighting pilot to locate an enemy aeroplane; in fact he

The machine gun groove with barrel fixed for forward firing through the propeller arc is shown in black. Another gun is carried on the opposite side

will not usually be able to do so without the assistance of a ground organization of sound locators and searchlights.

The Future.—The performance of aeroplanes is gradually improving. This is unlikely, however, to affect air tactics greatly, unless one nation falls far behind another in air development.

It is probable that the calibre of the guns carried in aircraft will increase. The chief obstacle to this is the great increase in the weight of the ammunition involved in even a small increase of gun calibre.

It is possible that aeroplanes will be armoured. But here again considerations of weight apply.

Finally, radio telephony, which enables pilot to speak to pilot in the air, will undoubtedly make for better co-operation in a fight-

FIG. 6.—LINE OF ATTACK ON TWO-SEATER FROM THE "BLIND SPOT"
By approaching along the line indicated the attacking pilot is immune from the fire of the enemy and is himself well-placed to get in a burst of fire at close range

ing formation. Combined tactics of a more elaborate nature will be possible when the commander of a formation can give orders to his pilots by means of the spoken word. By this means also the size of the formation that can be controlled by one man will tend to increase.

AIR CONDITIONING. The term is derived from the word "conditioning" which was applied to the determination of the moisture content of textiles, and covers the treating of air in an enclosure to regulate its moisture content, temperature, purity and usually its circulation. For increasing human comfort and for the manufacturing or processing of certain materials, an accurate control of the moisture content of the air is most important. It is

sometimes roughly effected by adding water vapour or mist directly to the enclosed air, but more precisely by using an air-conditioning apparatus by which the air is purified and its temperature and moisture definitely controlled before it is introduced into the space to be conditioned.

Originally only places where equable and moist climatic conditions prevail, such as Lancashire, England, and the Fall River district in Massachusetts, could be chosen for the building of cotton mills. Then moisture was added to the air by evaporating water in steam pots. This method sufficed for small mills, but was inadequate in the larger mills on account of the heat generated by the great concentration of machinery. In the latter half of the 19th century the direct introduction into the room of an atomized spray of water both cooled and moistened the air, thus making it practicable to spin fine cotton yarns in all climates. At about the same time moist air was supplied to malting floors by passing the air through coke filters over which water trickled, or through a large series of wetted baffle plates. In 1897 Joseph McCreary of Toledo, O., patented an air washer intended primarily for purifying the air, but incidentally it cooled it and increased the moisture content. In 1906 Stuart W. Cramer of Charlotte, N.C., and Willis H. Carrier of Buffalo, N.Y., working independently, made two important contributions to the art. Cramer automatically controlled humidity by a system which depended upon the relation between the wet and dry bulb temperatures. This was applied to the humidifying spray heads located in the room. Carrier devised the "dew point control," an improved form of air washer which not only brought the air to saturation, but also controlled automatically the temperature of such saturation, thus determining the moisture content of the air supplied.

Types of Apparatus.—Of the two main types of humidifiers, the "direct spray" type, which provides for the atomization of the water and its introduction directly into the room, is made in relatively small sizes. The nozzles or distributors are placed just below the ceiling, and provide for humidifying only. The "saturated air" type, on the other hand, employs larger volumes of saturated air at the required temperature. In the conditioning chamber it is brought into intimate contact with water finely divided by spraying through special nozzles under moderate pressure. All of the free particles of water are then removed by an "eliminator," which usually consists of a series of specially formed baffle plates on which all free particles of moisture are caught, leaving the air saturated but free of all suspended water particles. The spray water may be heated or cooled, and the temperature of the saturated air may be modified before passing it into the room at the theoretic dew point. Portable self-contained humidifiers, operating on the above principle, are also employed.

Under certain conditions it is desirable to remove dust and soot from air without modifying its humidity. In such cases either "cloth filters" or "viscous filters" are employed. The cloth filters are large areas of closely woven cotton cloth held in frames, provision being made for frequent cleaning. The viscous filters are either intricate metal baffles or cells filled with masses of fibre-like metal. These are dipped in a viscous oil which causes the particles of dust or soot to adhere to the metal surfaces.

Usually temperature is automatically controlled by thermostats governing the admission of steam to the air heaters, or regulating the supply of cold dehumidified air. Another form controls the sprays, but is mostly used in the direct spray type humidifiers.

The quantity of moisture which may remain in the vapour state in a unit volume of space is dependent only upon its temperature. The saturation pressure of water vapour is approximately doubled for each 20°F rise in temperature, i.e., the maximum vapour pressure increases approximately in a geometric ratio for equal increments of temperature. The relation of the weight of water vapour in the atmosphere to the weight of air varies approximately in accordance with Dalton's law of partial pressures (see DALTON, JOHN). When water is brought into contact with unsaturated air it evaporates. If the air is the sole source of heat necessary to produce evaporation, an eventual equilibrium saturation temperature is established depending on the initial air temperature and its initial degree of saturation. The reduction in the *sensible heat* of the

atmosphere is equalled by the *latent heat* of the acquired water vapour; the *total heat* remains constant. The equilibrium temperature of evaporation is observed with practical accuracy by a wet-bulb thermometer. The general formula based upon this heat balance is:

$$W = [r'W' - C_{pa}(t - t')] / [r' + C_{ps}(t - t')]$$

in which

W = the weight of moisture per unit weight of pure air.

W' = the weight of moisture per unit weight of pure air saturated at the temperature t' .

$(t - t')$ = the true wet-bulb depression.

C_{pa} = mean specific heat of air at constant pressure between temperature t and t' .

C_{ps} = specific heat of water vapour at constant pressure between t and t' .

r' = latent heat of evaporation at wet-bulb temperature t' .

When unsaturated air is passed through an air washer and brought to saturation without changing the temperature of the spray water, it will be cooled to the temperature of evaporation

BY COURTESY OF COOLING AND AIR CONDITIONING CORPORATION

DESIGN OF AIR CONDITIONING APPARATUS FOR LARGE BUILDING

(substantially, to the wet-bulb temperature of the entering air). For example, when the outside air is at 95°, the average wet-bulb temperature will be approximately 75°, and the air passing through a spray humidifier will be cooled to substantially 75°. This method of cooling is especially valuable in textile mills and tobacco factories where the increased humidity as well as the lower temperature is desirable.

The temperature of evaporation is independent of the actual rate of evaporation. The rate of evaporation of water into air is dependent upon the air velocity over the water surface and upon the difference in vapour pressure existing between the water and the air. The determinations of these relationships have important applications in the drying of materials in air.

Regain.—The ratio of moisture content to the weight of dry material is technically termed *regain*. The maximum regain for various materials varies widely, the amount depending principally upon the relative humidity of the air and to a slight extent upon the temperature. There is, however, no exact constant ratio between change of regain and change of relative humidity. Materials such as natural and artificial silk, wool, cotton, yarn and tobacco are sold on the basis of a standard percentage of regain, so in the drying and manufacturing of these materials it is necessary to control their relative humidity.

Comfort.—The relation of moisture, heat and air motion to human comfort and physiological efficiency has been the subject of much research, which has determined the points of equivalent comfort, or temperature sensation. A mathematical curve can be drawn showing the relation between temperature and humidity which will give the same sensation of temperature. Such a curve is termed an "effective temperature" line. Temperature by itself, even when automatically controlled, does not determine comfort. Humidity is equally important. The proper relation between temperature and humidity can be maintained only by complete conditioning.

Some instrument of measurement besides the dry-bulb thermometer has yet to be devised as an indicator of comfort. One instrument attempting to accomplish this, devised by Sir Leonard Hill in England, was known as the "kata-thermometer." Under conditions of high humidity this is a reliable indicator but it does not follow with precision the experimental effective temperature lines under varying humidities.

AIR CO-OPERATION. A result of the growth of aerial navigation in the first quarter of the 20th century has been to accent the importance of co-operation between the air forces and the armies and navies of the countries of the world. The problems to be solved in the military and naval spheres though in some ways alike are in others so different as to make separate treatment desirable. (X.)

CO-OPERATION WITH AN ARMY

To gain information about one's enemy has always been one of the first preoccupations of a military commander, for, until he has accurate knowledge concerning the strength and dispositions of his opponent, it is difficult for him to evolve an effective plan to bring about the defeat of his enemy.

HISTORICAL

It did not need a very great stretch of imagination in 1903, when Orville and Wilbur Wright made the first successful flight in an aeroplane, to realize that it would be possible to obtain a great deal of the essential information concerning an enemy by flying over his positions. The practical realization, however, was slow, owing both to conservatism and technical difficulties. By the time the World War broke out in 1914, the French, Germans and British all had military aeroplanes; we were actually able to send out four squadrons of twelve aeroplanes each, with the original Expeditionary Force. The stage reached in technical progress was that aeroplanes and engines were sufficiently reliable to enable flights of 50 miles into the enemy's country to be undertaken. Although all the pilots and observers of these aeroplanes were Army officers, and many of them had passed the Staff college, it is fair to say that British military leaders were still rather sceptical as to the value of the information which could be obtained by this means. The one idea underlying the employment of the aeroplane at that time was that they should obtain information. The aeroplanes did not carry any armament, and only two had been fitted with wireless for experimental purposes.

As a result of the first few weeks of the War several new ideas emerged:—

(a) Several combats in the air took place during those weeks, revolvers and rifles being taken into the air for the purpose; and in some cases enemy aeroplanes were actually forced to land in our lines. In consequence it was realized that aeroplanes should be equipped with machine guns for the sole purpose of fighting

enemy aeroplanes. For this, special mountings were required. It was also realized that the easiest way to fight another aeroplane would be to point your own aeroplane straight at it, and be able to fire a machine gun straight out through the propeller. Actually, the first purely fighting aeroplane which achieved this was the German Fokker, which made its appearance in May 1915. Our first fighters were pushers (*i.e.*, they had the engine behind the main planes). It was not till 1916 that the Allies produced

CODE USED IN AIR CO-OPERATION WITH THE ARTILLERY
The clock figures used to indicate the position, and the concentric circles the distance, of the burst from the target. Thus "Z.IX." would indicate a burst of 50 yd. west of the target

their first aeroplane with machine guns capable of firing through the propeller.

(b) Many of the pilots, while carrying out reconnaissances found roads packed with German troops and transport. Small bombs were taken up and dropped over the side of the aeroplanes, with little effect. But it was speedily realized what havoc might have been produced if it had been possible to drop large bombs accurately. To do this, suitable bombs, the means of attaching them to and releasing them from aeroplanes, and a sight which would enable the bombs to be dropped accurately, had all to be designed and produced.

(c) The two aeroplanes (mentioned above) equipped with wireless, rudimentary though it was, immediately became in great demand, and it became obvious that reconnaissance aeroplanes would have to be fitted with wireless as soon as practicable.

(d) The idea of taking photographs from aeroplanes as a useful adjunct to the usual reconnaissance report, was also initiated by some photographs being taken over the side of an aeroplane with a press camera. From this it became evident that the information contained on such photographs was of the utmost value to the general staff. To do this on a large scale many new things were necessary; a suitable camera, which could be fixed on to an aeroplane, and mobile photographic workshops in which developing, printing and camera maintenance could be carried out.

As a result of these early ideas, a vast air organization grew up. Instead of having one type of aeroplane as a "maid of all work," separate types were evolved for fighting, bombing, and the normal reconnaissance duties—and the pilots began to receive special training accordingly. In addition, vast specialist sections were trained to deal with wireless, photography, stores and overhauls of aircraft and engines.

POSITION AT THE END OF THE WAR 1914-18

By the end of the War, the force, which by then had become the Royal Air Force, was organized in brigades, wings and squad-

rons. One brigade was allotted to G.H.Q. This brigade had two wings, one of bombing squadrons and one of fighters. These bombers were used for carrying out long distance reconnaissance and bomb raids under G.H.Q. orders; the fighters were utilized to reinforce the brigade allotted to each army, according to the requirements of the situation. These brigades usually consisted of one wing of bombers, one of fighters, and one corps wing. From early in the war, one squadron had been attached to each corps (these squadrons are now called army co-operation squadrons). These squadrons operated under the orders of the corps to which they were attached, and carried out reconnaissance up to a depth of about eight miles, photography of the whole corps front, and supplied all the observation for the artillery. All aeroplanes working for the artillery were equipped with wireless telegraphy. Those carrying out reconnaissance duties, in addition to making out a written report on their return to the aerodrome, used to drop messages on the headquarters for which they were working. In addition to these allotments, special provision was made to provide co-operation for the Tank corps, one corps and one fighter squadron being allocated for this work.

CO-OPERATION AS ENVISAGED IN THE YEAR 1928

In a war of any magnitude it is reasonable to assume that very large air forces will be employed on each side. These are likely to consist of squadrons of the following types and capabilities:

(a) *Army Co-operation.*—Consisting of two-seater aeroplanes capable of staying in the air about three hours, fitted with either radio telephony, or wireless telegraphy, a camera and defensive equipment in the form of machine guns. Their first duty is to obtain information, and they should only fight when forced to do so. In the British Air Force, the pilot carries out all the observation work, the passenger being employed in looking out for enemy aircraft.

(b) *Day Bombers.*—Day-bombing aeroplanes will probably have a radius of action of about 200 m., and be capable of carrying about 500 lb. of bombs; they can also be fitted with wireless telegraphy and a camera for occasions when they are employed on reconnaissance duties.

(c) *Night Bombers.*—Multi-engined aeroplanes, which will be capable of carrying about one ton of bombs, with a radius of action of about 500 miles.

(d) *Fighters.*—Single-seaters, very fast, able to climb and manoeuvre very rapidly. They will be employed chiefly in fighting enemy aircraft.

The organization of these squadrons would be in groups and wings since the group has now taken the place of the brigade. Instead of there being one army co-operation squadron per corps, there would normally be one army co-operation wing with each corps, composed of a number of army co-operation squadrons equal to the number of divisions in the corps. The actual number of army co-operation squadrons may, however, vary as the size of the force increases. Having shown the types of aircraft that the commander-in-chief of an army would have at his disposal, it is now proposed to discuss their employment in helping the military force to achieve its object. These duties will be examined under the following headings: reconnaissance, artillery, co-operation, offensive action and protection.

Reconnaissance.—Before a military commander can formulate a definite plan for the defeat of his enemy, he must have ample information concerning him. He must know where the enemy has his main force, the line along which he is intending to develop his attack, the location of his reserve troops, and whether or no the enemy has troops working round his flanks. A military commander has several sources of information—from spies, from captured prisoners, reports coming through neutrals, and possibly captured orders. All these will give him a portion of the information he wants, but even when he has pieced together all the evidence available from these sources, the real movements of the enemy will, in all probability, be a matter of conjecture, arrived at by drawing deductions from the incomplete information available. The enemy is likely to secure the movements of his force by a screen of mobile troops. In the days before aero-

planes, a commander would seek to gain information concerning the movement of the enemy's main forces by using his cavalry to penetrate this screen. The information so obtained might prove very costly in casualties, much of the information obtained would, in all probability never get back to the commander who required it, and would only reveal what was happening at certain points, where the screen had been penetrated. In other words, the military commander would still feel that he wanted to see what was really happening the other side of the hill. Having aeroplanes at his disposal enables him to accomplish this. His day bombing aeroplanes have the additional function of carrying out long distance reconnaissance. By this means he is able to direct his reconnaissance aircraft as far as 200m. into enemy country, and from the information which they obtain, and from the information available from the other sources already mentioned, the military commander should be able to anticipate the plan of his enemy.

It must not, however, be supposed that these reconnaissance aeroplanes can be sent such a distance at a height from which it would be easy to see with the eye what was happening on the ground. They will carry out this duty singly, flying at about twenty thousand feet, and by far the greater proportion of their information will be obtained by taking photographs of the important points over which they pass. Consequently, the success of the reconnaissance will, to a great extent, depend on the accuracy with which the military commander has chosen the places to be reconnoitred. By means of this long-distance reconnaissance, a military commander will be able to obtain his strategical information; his subordinate commanders, however, will require much tactical information concerning the enemy's movements within 50m. of our own troops. Thus, a corps commander will want to know if the enemy is increasing the number of troops in his area, or if there are any signs of a withdrawal; early information of the presence of tanks is particularly important. Again, a divisional commander will require the fullest details of what is happening on his immediate front. He will want to know where the enemy has his reserves, where he is digging trenches, and details of his disposition.

This reconnaissance for corps and divisions will be carried out by the army co-operation squadrons. These squadrons are usually allotted to a corps on the basis of one per division in the corps. The squadrons in each corps are administered by a wing headquarters, which will be situated at corps headquarters, the wing commander acting as air adviser to the corps commander. If the war is one demanding the maximum effort, and a national army is produced, the allotment of army co-operation squadrons may be altered from a divisional to a corps basis. The reconnaissance for corps and divisions will be carried out at a much lower height than the strategical reconnaissance, and consequently much information will be obtained from the actual observation made by the pilot. It is obviously essential that it should be transmitted without delay to the military commander who has ordered the reconnaissance. For the reconnaissance carried out for corps, aeroplanes are fitted with wireless telegraphy. The messages are received at corps headquarters direct, and, if he wishes, the corps commander can also communicate with the aeroplane by this means. The aeroplanes carrying out reconnaissance for a division are in very intimate touch with the divisional commander, since they are equipped with radio telephony sets, which enable the pilot to telephone his reports direct to divisional headquarters, and also make it possible for the divisional commander to telephone instructions to the pilot in the aeroplane. Besides this visual reconnaissance, these aeroplanes carrying out reconnaissance for corps and divisions take many photographs, from which the staffs of these formations can draw an accurate picture of the enemy's organization and disposition.

Artillery Co-operation.—An important part of the work of the army co-operation squadron is co-operation with the artillery. The undulations of the ground often make it impossible for artillery commanders either to find suitable targets to aim at, or to be able to range their guns on to important points, such as bridges and crossroads, which they may want to shell. Consequently,

aeroplanes are employed to "spot" the positions of enemy batteries. This is usually done by seeing the flash of the enemy guns when they fire, and then sending down their position by wireless. These reports are usually confirmed by photographs, which show clearly where the enemy batteries are. Other targets, such as bodies of troops or transport, are also reported to the artillery. If the artillery commander wishes it, a pilot having "spotted" a target can range a battery on to it. This is effected by means of a simple code, the target being taken as the centre of a clock, twelve o'clock always being the north point. Imaginary circles radiate outwards from the centre of the clock at distances of 10, 25, 50, 100, 200yd., etc. These circles are lettered, the corrections to the guns being sent down by sending the letter of the distance circle followed by the hour of the clock. "A" is the letter for the 100yd. circle. Thus, if the shell burst 100yd. due east of the target, the correction would be A.3. (*i.e.*, 100yd. at 3 o'clock). By this means our aeroplanes are able to tell the battery commander exactly where his shells are falling, it being his province to work out the actual corrections for the guns. To receive these messages, artillery brigades and batteries are equipped with wireless telegraphy receiving sets (*see fig.*, p. 446).

Offensive Action.—The duties described above, which are performed by aircraft assisting the army, are confined to obtaining information. A military commander will, however, have at his disposal bombing aeroplanes, which if directed on to suitable objectives, may have a far-reaching effect on the course of the campaign. Having gained information concerning the movement of his enemy's main forces, he will obviously try to hamper the enemy in the achievement of his plan, and the weapon with which he will be able to strike his enemy first, and nearest his vitals, is his bombing force. For the employment of this force, he has before him three main courses. He can direct it against his enemy's industrial areas, his communications, or his troops, if in a favourable situation to offer a target. He should select one of these objectives, and concentrate his whole strength on it, for, to be effective, bombing must be concentrated and continuous. A military commander, by concentrating a big bombing force on to the enemy's industrial area, can reduce enormously their output of the munitions, clothing and food which are essential if their armies are to be maintained in an efficient fighting condition. In choosing such a target as this, a military commander would have as his object the cumulative effect of the raids over a period probably lasting several months. The military commander may want to produce some more immediate effect on the situation; for instance to prevent reinforcements and supplies from reaching an area in which he intended to strike some decisive blow. An effective way might be to create a block on a railway or a main road, and having created it, to maintain it by subsequent bombing raids at frequent intervals both day and night. As a general rule, the further back a line of communication can be blocked, the more extensive will be the area affected.

Situations will arise occasionally, when the employment of aircraft to attack tactical targets is imperative. These occasions will occur at the most critical moments of the land campaign. For instance, if one's own army were retreating, all available bombers, and possibly fighters too, would be turned on to attack the advancing columns of the enemy so as to disorganize their advance and give our own army time to get established on a defensive position. Conversely, at the crisis of some great offensive, the enemy army might just be breaking and starting to retreat; then every available aeroplane would be concentrated on the creation of such havoc amongst the retreating columns of the enemy that the retreat would be turned into a rout.

Protection.—For a commander to obtain the full value of his reconnaissance and offensive action, he must be protected against similar enemy action. He will, in other words, wish to attain and maintain, air-superiority. To enable him to achieve this, he will have fighter aircraft whose main function is to fight enemy aircraft, and enable the reconnaissance and bombing aircraft to carry out their work without undue interference. Experience in the past has shown that air-superiority is apt to fluctuate. One side will suddenly bring several new squadrons into the field, or

re-equip all its fighter squadrons with a new type of aeroplane more efficient than the fighters of the other side. Consequently a continuous progressive effort is required, and even then, it is difficult to ensure the continuous maintenance of air superiority.

The Future.—To look into the future at a transitory stage like the present, is difficult. Most of the great Powers are thinking about mechanization. The mechanization of armies, however, will not alter the principles underlying the conduct of a land campaign, and, consequently the requirements of mechanized armies will probably be much the same as those equipped with the present day appliances. The air units working with mechanized forces will obviously have to be highly mobile. There is, however, a possible development which may take place, in which the attainment of the ultimate object (the subjugation of the will of the enemy people) will be achieved by the air rather than the land forces. In such a case, the function of these highly mobile land forces would be to secure suitable bases from which great bombing formations could strike at the vitals of the enemy nation.

(T. L. L.-M.)

CO-OPERATION WITH A NAVY

The object of aircraft co-operation is to assist a navy in the destruction or neutralization of a hostile battle fleet, and in the control of sea communications. Aircraft can afford indirect assistance in battle by providing information of enemy naval forces obtained from long-distance or close reconnaissance, and can give direct assistance by offensive action against enemy surface and submarine craft with torpedo, bomb, and machine-gun. It is also their duty to afford protection to a fleet from enemy aircraft by attacking them in the air, on the sea, or at shore bases, and thus deny the enemy the use of his aircraft. In the control of sea communications, aircraft can be employed on reconnaissance, anti-submarine patrol, convoy escort, and for torpedo and bomb attacks on enemy forces which dispute control. Aircraft for naval co-operation operate from aircraft-carriers and from shore bases within flying range of the fleet. Aircraft borne in carriers are specially designed for launching from and alighting on their carriers, and are called ship-planes. They may be landplanes, float-planes (aircraft provided with floats for alighting on the water), or amphibians (aeroplanes which can alight on or rise from both land and water). Shore-based aircraft may be landplanes, seaplanes (floatplanes and flying-boats), amphibians, or lighter-than-air craft.

HISTORICAL

Prior to the War 1914-18, there were few instances of aircraft co-operation with a fleet, although seaplanes took part in the British naval manoeuvres of 1912-13-14. At the outbreak of war in 1914 none of the Powers had many naval aircraft, and the development of naval aviation was slow; in fact throughout the whole war the development of aircraft for naval purposes was not as rapid as that of aircraft for work with land forces. Perhaps the hardest problem was to provide aircraft to work with a fleet operating beyond the limited range of aircraft based on shore. Seaplane carriers were hastily improvised from fast merchant steamers, but the inability of the seaplanes of that time to rise from a rough sea, and the risk from submarine attack when stopping to hoist the seaplanes in and out, militated against their use. However about a dozen ships were so equipped by the Allies, and their aircraft were able to carry out observation and bombing flights.

To cope with the Zeppelins used by the Germans on long-distance reconnaissance, experiments were begun in Nov. 1915 in flying small fighting landplanes from British cruisers and seaplane carriers. These were successful, and in Aug. 1917 a Zeppelin was shot down by an aeroplane from the British cruiser "Yarmouth." The practice of carrying landplanes in fighting ships was extended in 1918 to all British battleships, battle-cruisers, and cruisers; the two former types carrying in addition to a fighter a two-seater aeroplane for observation duties. Flights were thus possible in weather which precluded the use of seaplanes. Such aircraft were, however, unable to return to their

ships, and were forced to fly to the nearest land or alight on the water.

In the meantime experiments in landing aircraft on the decks of specially designed ships had been progressing. In Aug. 1917 an aeroplane alighted on the deck of a ship for the first time, and in Oct. 1918 the British aircraft carrier "Argus," constructed for aircraft to fly both on and off, was commissioned for service in the Grand Fleet.

As regards employment, naval aircraft played a small part in close co-operation with the fleets in the War 1914-18. Seaplanes, kite-balloons, and airships carried out limited reconnaissance for the Grand Fleet, one British seaplane being present at the battle of Jutland. This aircraft sighted the German light cruisers, but low visibility prevented further observation, and only one flight was made. Seaplanes and kite-balloons were also used to observe the fire of the monitors off the Belgian coast, and of the bombarding ships in the Dardanelles. In the German fleet, Zeppelins provided valuable reconnaissance by reporting the approach of British surface craft, and by keeping down British submarines in the Heligoland Bight. The value of aircraft observation was greatly enhanced by developments in wireless telegraphy from the air.

Except for a few German attacks on British shipping in 1916 and 1917 and the attack on the Turkish battle-cruiser "Goeben" aground in the Dardanelles in 1918, there were very few instances of bombing attacks on surface craft at sea. Many naval objectives on shore, however, were bombed; as examples, Cuxhaven in 1914, the airship sheds at Dusseldorf and Friedrichshafen in 1914, the Zeppelin sheds at Tondern in 1918, and the intensive bombing of submarine bases in Flanders throughout the war.

Although as early as 1913 a Sopwith seaplane had carried a torpedo, the first torpedo attack by aircraft was carried out on Aug. 12, 1915, when for the first time in history a seaplane from the British seaplane carrier "Ben-my-chree" sank a steamer off Gallipoli. This form of attack was, however, slow to develop, and although in Oct. 1916 the British Admiralty decided to build large numbers of torpedo aircraft, it was not until three weeks before the Armistice that a squadron of torpedo-carrying aircraft was ready for service in the Grand Fleet.

By far the largest parts played by naval aircraft were those of anti-submarine patrol and convoy escort. Airships, kite-balloons, seaplanes, and, in 1918—when the supply of aircraft for the western front exceeded the demand—landplanes, were all used on these duties. From the first days of the war, when the British Expeditionary Force was crossing to France, until the Armistice, areas round the British Isles, off the Belgian coast, and in the Mediterranean—small at first, but increasing rapidly in size as the supply of aircraft became more plentiful—were systematically patrolled by aircraft: as the result, submarine activity was greatly reduced. Only 10 of the 178 German submarines sunk by anti-submarine measures were actually sunk by aircraft, although another 21 were probably seriously damaged, but the value of aircraft thus employed lay in their power to harass the submarine commander, to force him to dive to escape detection, to prevent him from taking up a suitable position for attack, and to locate submarines for their subsequent destruction by surface craft. In 1917, when the convoy system was introduced for the protection of merchant shipping, air escort was provided and a fair measure of security was afforded to convoys. For example, from April 1917 to Nov. 1918, neglecting ocean convoys, a total of 312 ships were torpedoed in convoy, but only two of these attacks occurred when vessels of the convoy were under air escort.

MODERN DEVELOPMENTS

Since the War 1914-18, rapid developments have been made, and aircraft now form an integral part of a modern fleet. Their employment may conveniently be discussed under the headings of carrier-borne aircraft and shore-based aircraft.

Carrier-borne Aircraft.—Aircraft carriers provide the aircraft for close co-operation with the battle-fleet. Their duties are reconnaissance prior to and during action, observation of gunfire, attacks on enemy ships with torpedo and bomb, and air fight-

SIDE ELEVATION AND FLIGHT-DECK PLAN OF A MODERN AMERICAN AIRCRAFT CARRIER

The Landing Net will be seen just before the recessed stern portion of the flight deck; it is about 100 ft. long. Before it is a large T-shaped elevator for moving aircraft from the flight to the hangar deck. There is another and similar T-shaped elevator abaft of the cage mast. Before the mast, disposed as one to port, one to starboard, are two aircraft catapults, worked by compressed air and capable of launching the heaviest aircraft.

ing. Early and accurate information of the enemy is of paramount importance to a naval commander to enable him to dispose his fleet. To obtain this information aircraft patrol ahead of and on the flanks of the fleet, and, when action is joined, they observe and report the movements of individual units of the enemy fleet, and control the effect of gun-fire. Only second in importance to the work of reconnaissance is the observation of gun-fire. By reporting the range, course, and speed of the enemy and observing the fall of shot, aircraft enable a fleet to engage a target which, owing to low visibility, smoke-screens, or the long range of modern guns, may be unseen.

Another function of aircraft in carriers is to fire torpedoes and to drop bombs. This is done by torpedo-bombers, aircraft which carry a torpedo or the equivalent weight of bombs. Torpedo-carrying aircraft can be employed against ships at sea or at anchor. Although, at the present state of development, to release their torpedoes the aircraft must fly close to the water and may thus offer a target for gun-fire, nevertheless their high speed, and the possibility of sun, haze, low clouds, or smoke, may enable them to approach undetected, and so provide an invaluable tactical weapon. If bombs are carried, the objective may be ships at sea, ships in harbour, or shore targets. The effect of bombs against modern armoured ships is largely conjectural. Trials against ex-German warships have been carried out by Great Britain and the U.S.A., but the results were inconclusive. With the development of armour-piercing bombs, however, this form of attack would appear to offer great possibilities.

A third duty of carrier-borne aircraft is air fighting. In order to provide freedom of movement in the air for aircraft employed on observation or other duties, it is essential to neutralise the action of enemy aircraft. Obviously the most satisfactory way of achieving this is to destroy the sources of enemy aircraft which, in a fleet at sea beyond flying range from shore bases, are the aircraft carriers. Since low visibility and the large area involved may render the discovery of enemy carriers impossible, resort is had to single-seater fighters—small, fast, highly manoeuvrable aircraft—to seek out hostile aircraft in the air and to provide protection for friendly observation aircraft. These fighters may also be employed to attack lightly-armoured ships with machine-guns and small bombs.

Shore-based Aircraft.—These, if within range of a naval battle, will be called upon to carry out any of the duties performed by carrier-borne aircraft, but they will more often be employed to co-operate with a fleet in its function of controlling sea communications, and their work will then consist in reconnaissance, anti-submarine patrol, convoy escort, and torpedo and bombing attacks. Reconnaissance may take the form of independent long-distance reconnaissance of enemy forces and bases, trade routes, and focal areas, or of close reconnaissance in co-operation with surface craft. Reliable information of enemy movements or defences, confirmed if possible by photographs, will

be most valuable. Anti-submarine patrol is perhaps the most important duty falling to the lot of shore-based aircraft. Shipping of all kinds requires protection from enemy submarines: areas round the coasts and on the trade routes—particularly in areas where shipping routes converge and in narrow waters—require constant patrolling. Such patrols may be carried out by aeroplanes operating independently of ships, but the experience of the War 1914–18 has taught that it is not by one weapon alone that submarines are destroyed but by the cumulative efforts of air, surface, and submarine craft working in close co-operation. Further, convoys of merchant ships lightly escorted by surface craft are very vulnerable to attack by hostile surface, submarine, and aircraft, and will be escorted whenever practicable by aircraft in order that they may give warning of the approach of enemy forces, attack submarines, and warn the convoy of the presence of mines. Attack by shore-based aircraft with torpedo or bomb against ships at sea or in harbour will not differ from that on similar targets by carrier-borne aircraft, though it may be necessary to operate from advanced bases to be within flying range. Shore-based aircraft will afford a valuable coast defence weapon.

Aircraft Carriers.—Under the terms of the Washington Treaty the total tonnage of aircraft carriers allowed to each of the Contracting Powers is limited and is as follows:—British Empire and U.S.A. 135,000 tons, Japan 81,000 tons, France and Italy 60,000 tons. At the end of 1927, the aircraft carrier tonnage was:—British empire 69,900 tons, Japan 27,000 tons, U.S.A. 14,700 tons, France 21,000 tons, and Italy nil.

FUTURE DEVELOPMENT

Experience gained in the War of 1914–18 and since, under active service conditions, is limited. Thus the functions of aircraft in naval warfare are largely conjectural. They would appear, however, to depend on two factors, namely: the degree in ease of operation of carrier-borne aircraft, and the development in endurance and seaworthiness of the flying-boat type of aircraft.

(D. G. D.)

AIRCRAFT CARRIER. The advent of the aeroplane has provided navies with a new means of reconnoitring for an enemy; of observing his movements; and correcting gunfire. In fact, aircraft have joined the cruiser of to-day, the frigate of old, as the "eyes" of the fleet. Moreover, they have extended the vision of an individual ship from that due to the height of her mast-head to one limited only by the range of an air observer who can maintain wireless communication. In addition they have provided a new method of attacking naval objectives by means of bombs and by torpedoes launched from the air.

To be of practical value to a fleet at sea, however, it is necessary that naval aircraft should be available whenever their services may be required, and weather and other conditions permit of their being used. Owing to their limited fuel endurance and inequality

A.A. = Anti-aircraft.

of speed with ships, it is impracticable for aircraft to fly continually with the fleet. Flying-boats, capable of moving on the surface, have not yet been sufficiently developed to withstand the buffeting of what, for ships, would be very moderate seas. They can, therefore, only operate with a fleet which is within easy range of a sheltered base.

The alternative to summoning aircraft from a shore base is to carry aircraft with the fleet and launch them into the air as and when required. Owing to the innumerable obstructions on the upper deck of a warship, it is very difficult even to find stowage room for more than one or two aircraft, and quite impossible to provide the necessary space for them to alight on the deck; but in some of the latest ships in modern navies arrangements are now fitted for aircraft to be projected into the air by a species of catapult. All of the battleships and new cruisers of the United States Navy carry aircraft, and many of them are fitted with catapults.

In order to provide the necessary number of aircraft which a fleet will require in the future, and a suitable ship for them to return to when they have completed their flight, the aircraft carrier has been designed. This type of vessel combines a roomy hangar with a clear, flush deck, free from obstructions, for taking off and alighting. At the same time it has introduced a new problem in fleet tactics; for the aircraft carrier can only work her aircraft by steaming into or directly away from, the wind, which may result in her becoming detached from the main fleet during an engagement. This, and the fact that, by the nature of her construction, she is very vulnerable and a large target, means that she is a comparatively easy prey to a force of enemy cruisers. In other words, aircraft, carried in carriers, will operate in a fleet action with the handicap that their mobile base is not a very secure resting place either for their departure or return. This, and the limitations imposed on them by bad weather, fog and darkness, preclude their becoming a complete substitute for cruisers and destroyers, for, clearly, the fleet cannot be dependent on intermittent scouting, and it may often be under just such conditions as prevent aircraft operating that information concerning the enemy, and a means of countering his own light craft, are most important. In other words, aircraft and their carriers have become indispensable auxiliaries to navies, but they cannot replace the older types of warships.

(E. A.)

Types of Aircraft Carriers.—Between 1910 and the beginning of the World War, trial flights had been made from warships in

the U.S. and British Navies, but the progress made was slow, and it was not until just prior to the outbreak of war in 1914 that a vessel was taken in hand for conversion to an aircraft carrier. The British Government then took over a tramp steamer, renamed the "Ark Royal," and fitted her with a flying-off deck forward and two cranes for lifting the seaplane inboard after returning from a flight. In the summer of 1917 the first landing was made upon a British warship while under way.

Further carriers being needed, several passenger vessels were taken over and converted into seaplane carriers. The largest of these, the "Campania," was taken up in 1915, and a large flying-off deck fitted forward for the purpose of flying seaplanes off wheel trollies. These alterations were completed early in 1916, and proved fairly successful. A demand arose for further carriers to accompany the British fleet at sea. Amongst the smaller vessels adapted as carriers were the "Riviera" and "Engadine," the latter being the only carrier present at the battle of Jutland. Later the "Pegasus" and "Nararia" were similarly equipped.

The next vessel taken over was the Italian passenger and cargo ship "Conte Rosso," renamed "Argus," which in 1916 was building at Beardmore's. A complete flying deck was fitted fore and aft with a hangar for stowing the machines under this deck. The funnels were made to run horizontally beneath the flying deck to the stern, so as to discharge all funnel gases abaft the stern with the aid of fans. For transporting purposes lifts were fitted from the hangar to the flying deck, and cranes to lift the machines from the water. To enable machines to be carried on the deck in addition, wind-breaking palisades were fitted which could be raised simultaneously above the level of the flying deck. The "Argus" was the first ship to prove a really satisfactory carrier on which aeroplanes could alight and fly off with safety. Workshops were fitted on board and the vessel was, in fact, a floating aerodrome which could accompany the fleet in all circumstances.

Whilst the first trials of this vessel were proceeding, early in 1917, it was decided to appropriate the "Furious," then completing at Messrs. Armstrong's naval yard, for aircraft-carrying purposes. This ship was originally designed as a large light cruiser to carry two 18in. guns in single turrets, one forward and one aft. The first stage of conversion was to remove the forward turret and fit a flying-off deck and hangar, and from this deck seaplanes and aeroplanes could be flown off successfully. Later, the stern 18in. gun was removed, and a big flying-on deck fitted, the two flying decks

FRENCH, BRITISH AND UNITED STATES AIRCRAFT CARRIERS WITH CLEAR DECK AND ISLAND LANDINGS

1. French carrier "Béarn," showing parasol type aeroplane taking off
2. H.M.S. "Courageous," which carries six flights of aeroplanes in hangar
3. The U.S.S. "Saratoga," upon whose flying deck the airship "Los Angeles" was successfully landed
4. H.M.S. "Eagle," showing the usual turtle deck aft. It has a capacity of 18 aeroplanes
5. H.M.S. "Hermes," with two two-seater "Panthers" forward and three single-seater "Flycatchers" aft
6. H.M.S. "Furious," which has accommodations for 36 aeroplanes

AIRCRAFT CARRIER

BY COURTESY OF AERO SERVICE CORPORATION

THE U.S.S. "SARATOGA," LAUNCHED IN 1925 AND COMPLETED IN 1927, WITH A CARRYING CAPACITY OF 72 AEROPLANES

Originally designed as a battle cruiser, the U.S.S. "Saratoga" is capable of very high speed, being equipped with all the recently developed improvements suited to naval mid-ocean bases

forward and aft being joined by a walking way around the mast and funnel. Owing to disturbances set up by funnel gases and eddies around the funnel structure, this flying-on deck was not a great success, and the ship was further reconstructed, being finally completed in 1925. This vessel was fitted, like the "Argus," with a clear fore and aft flying deck, the funnel gases being led out over the stern. She has two very large hangars, one above the other, and has a deck forward from which aircraft may fly off, in addition to the main flying off and alighting deck; this was an entirely new and important feature which is being copied in later aircraft carriers.

About the same time as the appropriation of the "Furious" for conversion, designs were prepared for a carrier named the "Hermes," and this was the first vessel primarily designed as an aircraft carrier. Some six months after, the Chilean battleship "Almirante Cochrane," building at Messrs. Armstrong's works, was taken over for conversion and renamed the "Eagle."

The "Island" Type.—In both these vessels a departure was made in the construction of the flying deck, since a completely clear fore and aft deck was not fitted, as in the "Argus" and "Furious." The funnels and navigating positions were incorporated in an "island" arranged on the starboard side, thus giving a clear deck of a width only slightly less abreast the island than just forward or aft of it. This feature is shown in Pl. I., figs. 4-5.

Following on the satisfactory results obtained with the "Furious," it was decided, in 1926, to convert the two larger light cruisers "Courageous" and "Glorious" into aircraft carriers. In these two ships a reversion is made to the island type, as in "Eagle" and "Hermes," and the clear deck, as in "Furious" and "Argus," is not repeated. The island type has also been adopted in the U.S., French and Japanese navies, but it is still doubtful which type will eventually prevail.

This question of the choice between the clear deck, with no obstruction at all, and the alternative of the island type—that is, with the navigating position and bridge, with all instruments such as range finders, fire control, etc., and the mast, funnel and perhaps some guns, all being located in a small, very narrow space on one side of the deck, as shown in the photos of "Hermes" and "Eagle"—is a much disputed one. The clear deck has the advantage of presenting no obstruction whatever to the aeroplane pilot as he approaches the ship with the intention of alighting on deck. The island type, whilst providing a much better navigation and control position on an elevated bridge, presents a serious obstruction on one side of the ship, and the pilot, in alighting on board, must so steer that, whilst one wing is in no danger of touching, the other is clear of the island standing up on that side of the deck. Some pilots, however, prefer the island, which gives them a good indication of the exact height they are above the deck when about to alight, it being more difficult to estimate this height with accuracy in the case of the clear deck. The stern view photograph of H.M.S. "Eagle" indicates very well the kind of view of the ship which is presented to the pilot when approaching to alight on board; it shows the deck curved downwards towards the stern to help him, in case the ship is rising and falling in the swell of the sea, and it also shows a good view of the island on the starboard side.

How Aeroplanes Board Ship.—It should be explained that the aeroplane about to land on board must always approach from behind the ship; the ship herself must, both for flying on and for flying off, be head to wind and steaming directly into the wind at a good speed. The speed of the ship therefore assists the aeroplane to alight on deck against the wind, and also helps the plane to rise when taking off. Speed has a double value for aircraft carriers, as it helps in alighting and flying off, and also enables the carrier to keep pace with the fleet, to retreat rapidly in case of attack by superior forces, or to regain station if separated from the fleet.

United States Aircraft Carriers.—In addition to a carrier named "Langley," which is comparable with H.M.S. "Argus," but of less speed, the U.S. Navy completed in 1928 as aircraft carriers of the island type, two very large vessels, the "Saratoga" and "Lexington," which were originally laid down as battle

cruisers. These vessels will have a very high speed, and will carry 70 to 80 aeroplanes, and in addition will have a 50% reserve carried in crates.

French Aircraft Carrier.—The French Government has recently completed a carrier named "Béarn" which is of the island type, and is a converted battleship. In many respects it closely resembles the British carrier, H.M.S. "Eagle."

Japanese Aircraft Carriers.—The "Hosho" is an aircraft carrier on similar lines to H.M.S. "Argus," except that the funnels come through one side of the ship, and can be laid level along the side below the height of the deck to facilitate flying on and off the deck. Two other large aircraft carriers, the "Akagi" and "Kagu," were being converted in 1928, the first from a battle cruiser and the second from a battleship. It is understood they are both of the island type, but in other respects resemble H.M.S. "Furious."

WASHINGTON CONFERENCE RESTRICTIONS

Restrictions on aircraft carriers formed part of the Washington Treaty (*q.v.*). These restrictions implied that the aircraft carrier is now recognized as a definite and essential unit in a modern fleet. The other naval Powers followed the British lead in building this type of war vessel, and the aircraft carriers in service and building in 1928 for all Powers are shown in the table given. This table is restricted to aircraft carriers proper, the earlier and smaller vessels being excluded. (E. T.-D'E.)

AIRCRAFT IN WAR. Airships and aeroplanes, as distinct from captive balloons, were first used in warfare by the Italian army during the campaign against the Turkish forces in Tripoli in 1911 and 1912. With the exception of aerial combat, there being no enemy aircraft to encounter, most of the features of modern air warfare were introduced by the Italian airmen. Both aeroplanes and airships were used extensively for reconnaissance work; the Turkish positions were frequently bombed by both types of aircraft, which in some cases received damage from rifle fire and from guns trained vertically by the simple expedient of placing them on the slopes of hillsides; and enemy troops were subjected to fire from aeroplanes armed with rifles and revolvers. Extensive photographic reconnaissance flights were made by airships and the photographs obtained formed into a mosaic from which a revised general staff map of the Tripolitan area was prepared.

The World War.—In the World War the first squadrons of the British Royal Flying Corps flew from Dover to France on Aug. 13, 1914. Squadrons 2 and 4 were homogeneously equipped with B.E.2 type aeroplanes, but Squadron 3 had both Bleriot monoplanes and Henri Farman biplanes, while 5 used Farman and Avro biplanes. Though the Lewis gun had been tested in an aeroplane in 1913, the adoption of machine-guns had not been general, and indeed no provision was made for the arming of these early machines, bomb sights and bomb racks being also lacking. This was partly because their primary duty was held to be visual reconnaissance, and partly because of the narrow margin of lift available, which prohibited any addition to the load beyond the weight of the pilot and of petrol. The same consideration prevented the carrying of cameras, but valuable work was done by the early reconnaissance flights, the first of which was made on Aug. 19. On Aug. 23 the reports of the massing of German troops led directly to General French's order for the retirement which saved the British army, and timely warning was given on Sept. 4 of the commencement of von Kluck's attempted enveloping movement against the French left, which led to the battle of the Marne.

The first approach to a fight in the air occurred on Aug. 22, 1914, when a German Albatross machine appeared over the aerodrome at Maubeuge and was chased by several British machines. Two days later the first German machine to be brought down was forced to land by machines of Squadron 2. It was considered at that time that the most suitable type for aerial combats was the slow two-seater Henri Farman with propeller in the rear giving a free field of fire for the observer armed with a rifle. Before the end of 1914 it was, however, beginning to be recognized

that the greater speed and manoeuvrability of the single-seater gave it advantages over the slower type. (See AIR COMBAT.)

The cessation of movement and settling down into trenches and a war of positions led to the development of aerial photography, in order that changes in the positions or sizes of enemy railheads, ammunition dumps and camps might be recorded. Early attempts at co-operation with the artillery also began,

FRAGMENTARY BOMBS AND A 4,000 POUND DEMOLITION BOMB

generally with the aid of coloured signal lights fired by the aeroplane to indicate the fall of shell; but as early as Sept. 15, 1914, an experiment in the use of wireless telegraphy on active service was made, and on Sept. 27 the R.F.C. headquarters wireless section was formed.

Air Fighting Develops.—Air fighting and organized bombing raids developed in 1915. Early in January the Germans made several raids on Dunkirk with a number of machines flying together, in place of the isolated attacks by individual machines which had hitherto been the practice. On Jan. 22, for instance, 13 machines appeared and dropped bombs on the docks. During the battle of Neuve Chapelle in March 1915, in addition to the routine work of reconnaissance and artillery co-operation, the Royal Flying Corps interfered with the enemy's movements by attacking such important points on his lines of communication as Menin, Courtrai and Douai. During the battle of Loos, on Sept. 25, co-operation with the artillery was considerably improved and a system of "zone" calls introduced, by which the guns could be rapidly put on to "fleeing" targets.

The co-ordination of aeroplane bombing attacks with army operations was also further developed during this battle and attacks were made on railway lines, trains and important junctions. Early in March the R.F.C. had received the first batch of a newly designed aerial camera, from which greatly improved photographs resulted. In May the Germans produced the Fokker monoplane equipped with an interrupter gear which enabled the machine-gun to be fired through the revolving tractor screw blades, a device which took by surprise the Allied air services, which for some time to come were to continue to rely mainly upon "pusher" machines for fighting. At the beginning of 1916 the uses to which British aeroplanes were being put were reconnaissance, artillery observation and bombing with B.E.2 machines; and aerial fighting with Vickers and F.E. two-seaters, and with D.H.2 single-seater "pusher" machines and the new Bristol Scout single-seater tractor biplane with a machine-gun firing over the airscrew. The universal adoption of the tractor type for fighting was still awaiting the synchronized gear operated by the engine for firing through the airscrew, which appeared on the curiously named Sopwith "Pup," a high performance scout, in the summer of 1916. Squadrons for the definite purpose of fighting in the air were organized and a regular patrol was kept up by each squadron

over its own sector of the trenches to engage and drive back the enemy's long-range reconnaissance and bombing machines.

Verdun and the Somme.—During the battle of Verdun, which opened on Feb. 21, 1916, the French introduced a new and successful form of air fighting in sending their own machines into German territory to seek out the enemy machines before they reached the lines. This to a large extent enabled their own reconnaissance and artillery machines to do their work undisturbed. The Germans replied to this by developing the "circus" system, never copied by the Allies, of giving a recognized star pilot, or "ace" as the French called him, command of a special fighting squadron for which he chose his own pilots. The originator of this system was the German pilot Boelcke; another famous leader being von Richthofen, whose "circus" would move to different parts of the line, where the needs of the moment called for it, in an effort to obtain local air supremacy. The opening of the battle of the Somme on July 1, 1916, was signalized by intensive British reconnaissance and bombing flights, as well as by attacks with small 20-lb. bombs and machine-guns on the front line troops, in the trenches and billets and on transport immediately behind the lines. The same battle was also the occasion of the introduction of "contact patrol" work in an organized manner and on a large scale. This consisted in locating units of Allied forces, and keeping headquarters informed of the progress from hour to hour; reporting on the positions of the enemy, and in particular on movements of his reserves; transmitting messages signalled by the infantry from the ground to headquarters; and dropping ammunition and supplies to isolated bodies of troops.
